The furnace is heated by means of an air-cooled, step-down 2.5 kva. auto transformer. The primary is wound for 220 volts, having eight different taps for connections which enable a voltage range of from 20.7 to 38 volts on the secondary. This arrangement does not require the use of any outside resistance, as the current and temperature are controlled by means of the various contacts on the primary winding and also by varying the pressure of the electrodes on the granulated coke between the electrodes and the crucible. The transformer is connected to the furnace electrodes with stranded No. 0 copper cable.

The voltage and corresponding amperage for the eight steps on the primary winding are as follows:

Volts	Amp	20 per Cent Overload,		Volts	Amp	20 per Cent Overload,	
		Amp				Amp	
38 -	65	78	27.5	90	108		
35 -	71	85	25.2	100	120		
32.7	76	91	22.8	109	130		
30	83	100	20.7	120	144		

The amperes as given in the 20 per cent overload column may be drawn for short intervals (20 to 30 min.) without disastrous results on the transformer.

Temperatures as high as 2,200 to 2,300 C. have been obtained with the above, from a cold start, in 20 min. The cost of running is not over 30c. an hr. figuring 10c. a kw.-hr.

East Orange, N. J.

Use of Acetylene in Chemical Laboratories

The use of acetylene in chemical laboratories is rendered convenient by the adoption of an equipment placed on the market by the Prest-O-Lite Company.

The acetylene flame is sufficiently hot to bring about chemical reactions in the most refractory of substances, is economical and is ideal for convenient handling. The equipment is very compact, comprising only the familiar

LABORATORY EQUIPMENT FOR THE USE OF ACETYLENE

Prest-O-Lite tank and flexible hose to connect it to the burner. Used with the bunsen burner, acetylene produces an intense local heat exceeded only by the electric arc and the oxy-acetylene flame, and if it were desired to use the oxy-acetylene flame it would be necessary only to add a cylinder of oxygen, reducing regulator and blowpipe. When the gas is exhausted the acetylene tank is detached and a full tank is put in its place.

²"The Borchers Furnace," by F. A. J. Fitzgerald, *Electrochem. & Met. Ind.* (1905), p. 215.

³If graphite should be injurious to the substance being heated, the crucible may be lined with MgO, CaO, Al₂O₃, ZrO₂, etc., to prevent any action which might be caused by carbon.

Synopsis of Recent Chemical & Metallurgical Literature

Manufacture of Carbon Dioxide.—Very little has been published concerning the methods used in the United States for the production of carbon dioxide. Since it is estimated that over 100,000,000 lb. of liquid CO₂ is produced annually in the United States and Canada, the following outline of the process of manufacture, from a paper by G. H. TOMLINSON in the *Canadian Chemical Journal* for July, 1920 (p. 189), will undoubtedly be of interest:

The coal or coke used in its production is burned in the usual way under steam boilers, thus furnishing not only the raw material of manufacture but also all the power required for its purification and liquefaction. The flue gases leaving the boilers are first passed through an economizer to reduce their temperature and then through scrubbers to remove dust and sulphur dioxide. From these they go to an absorption system in which contact with an alkaline carbonate solution is effected and as much as possible of the CO₂ combined. The carbonated lye is drawn from here and pumped through a heat regenerator. It is then passed to the economizer, and, following this, is used to condense the steam given off with the CO₂ during the final heating. Its temperature is thus raised to the boiling point by otherwise waste heat alone. The "boiling off" is effected by utilizing the exhaust steam from the compressors, etc., which in a properly balanced plant is sufficient to maintain the necessary heat balance. The decarbonated or exhausted lye returns through the heat regenerator, giving up its heat to the carbonated lye, before again passing to the absorption system to renew the cycle just described.

The CO₂ which is liberated from the boiling bicarbonate solution is separated from the steam as previously noted, and after further cooling is compressed into the cylinders in which it goes to the trade.

From this description it can be seen that the two main objects to be accomplished for the successful working of the process are:

1. The recovery from the combustion gases of the maximum amount of CO₂ by bringing this into combination with the alkaline carbonate.
 2. The maximum dissociation of the bicarbonate thus formed with the minimum consumption of heat.
- A study of the reversible reaction

requires measurements of the dissociation tension of CO₂ for bicarbonate solutions at various temperatures. While such data are available for pure solutions of sodium and potassium bicarbonates (see accompanying table), in the commercial process mixtures of carbonate and bicarbonate containing from 30 to 75 per cent of the latter are encountered. Complete dissociation tension-temperature curves for such mixtures have not been determined. However, it is possible to make certain general deductions on the assumption that the dissociation tension will be higher as the temperature and the proportion of bicarbonate increase.

Let x = pressure of CO₂ in combustion gases entering absorption system.

x_1 = pressure of CO₂ in waste gases.

y = CO₂ tension of exhausted lye solution.

y_1 = CO₂ tension of carbonated lye.

The best recovery of CO₂ from the combustion gases will result when x is a maximum and x_1 a minimum. Similarly, the most favorable conditions for recovering CO₂ from the lye solution are y_1 a maximum and y a minimum. Now x will normally have its greatest value when the percentage of CO₂ in the gases approaches 20 and y will have its lowest value the more completely the lye is boiled and the lower the temperature at which absorption is commenced. In order to conserve heat the volume to be boiled must be reduced as much as possible by using concentrated lye solutions. The highest efficiency will be obtained when $x = y_1$ and $x_1 = y$. In practice this results when sufficient time is provided for the absorption (which should be conducted on the counter-current principle) and when the amount of carbonate present is exactly adjusted to the amount of CO₂ available.

DISSOCIATION TENSION OF BICARBONATE SOLUTIONS

Temp. Deg. C.	NaHCO ₃ mm. Hg	KHCO ₃ mm. Hg
15	120	461
30	212	...
40	356	...
50	563	...

From the accompanying table it will be seen that y is lower for sodium bicarbonate than for potassium bicarbonate. However, the limited solubility of the sodium salt is a disadvantage and a mixture of the two salts is found to be more efficient than either alone.

Theoretically, 1 lb. carbon should yield 3.66 lb. CO₂. Commercial results vary between 1 and 1.5 lb. CO₂.

On the Oxidation of Coal.—During the last few years a number of chemists have worked on the problem of determining facts which might help to establish the constitution of coal. The theory now predominating is that coal contains three constituents; namely, compounds of lignocellulose, proteins and resins. It is also known that pyridine dissolves only the resinous constituent. It has also been determined that coal oxidizes slowly in the cold, more rapidly at 100 deg. C., and that by this oxidation the coal loses its coking property. Boudouard attributes the coking power of a coal to a substance or a group of substances which by oxidation form humic products soluble in potash and giving a brown solution. According to recent theories the oxidation is produced by the intervention of special bacteria which start the reaction.

MARCEL GODCHOT has studied the mechanism of the oxidation of coals and presented the results of this work to the French Academy of Sciences (*Comptes rendus*, July 5, 1920, pp. 32-34). He worked on Blanzky coking coal of the following composition: 37.4 per cent volatile matter, 58.6 per cent fixed carbon and 4 per cent ash. The ultimate analysis on the ash-free basis is: Carbon 83.59 per cent, hydrogen 5.78 per cent and oxygen plus nitrogen 10.67 per cent. A 100-g. sample of the coal was treated with boiling pyridine. The brown amorphous pyridine extract obtained weighed 22.63 g. and its composition was: Carbon 83.45 per cent, hydrogen 5.84 per cent and oxygen plus nitrogen 10.51 per cent. Comparing these figures with those for the original sample, it is seen that

their compositions are quite identical. An important fact is that the coal after extraction with pyridine cannot be coked, but by mixing this coal with the pyridine extract the product becomes again just as good a coking coal as the original sample.

Samples of the original coal, of the coal extracted with pyridine and of the pyridine extract were kept for one month in an oven at 100 deg. C. The increase in their weight was respectively 3.15, 1.99 and 1.22 per cent. A mixture of an extracted sample of coal with its pyridine extract submitted to the same heat for the same length of time showed an increase in weight of 3.20 per cent, which is identical with the increase in weight of the original coal. All these oxidized samples give with potash a brown coloration.

After a study of these facts it is difficult to admit that the oxidation of the coal is the result of the action of bacteria pre-existing in the coal, because pyridine is a strong antiseptic, and still the pyridine-extracted coal, the pyridine extract and their mixture are readily oxidized. It seems that pyridine has broken up the coal into two separate oxidizable parts, of which one part plays the role of an oxygen carrier because the original coal and the reconstituted mixture oxidize more rapidly and in greater proportion than the two parts separated by pyridine treatment. The coking property of the coal is due to the constituent which can be extracted by pyridine—i. e., to the resinous constituent of the coal.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Production of Sulphur Dioxide.—The removal, and subsequent disposal, of sulphur dioxide from the gases of metallurgical plants is a problem which is becoming increasingly important. The production of sulphuric acid from these gases is not difficult, but sulphuric acid is a cheap and bulky commodity, the sale of which is confined to local markets; and its use, except in particular sections of the country, is limited as to quantity. The demand for liquid sulphur dioxide in manufacturing processes is increasing. Sulphur has a broader market than sulphuric acid and has the advantage of being more easily handled. Liquid sulphur dioxide is easily produced from concentrated sulphur dioxide gases by direct compression, and the direct reduction of concentrated sulphur dioxide gas to sulphur with coke is comparatively easy. For these reasons the production of concentrated sulphur dioxide gases in metallurgical operations is desirable.

FREDERICK LAIST and FREDERICK F. FRICK of Anaconda, Mont., purpose to produce concentrated sulphur dioxide gases in a practical and economical manner in such metallurgical operations as roasting, nodulizing and sintering and in blast-furnace and converter practice by supplying oxygen diluted with sulphur dioxide instead of air during these operations. The intense action of pure oxygen on sulphide materials is avoided by returning to the furnace a portion of the gases evolved in the roasting operation, the oxygen being

added to the cyclic gas in a regulated quantity. Concentrated sulphur dioxide gas may be produced by this method from the usual types of metallurgical furnaces with the addition of comparatively cheap and simple equipment. (1,344,905; June 29, 1920.)

Hydrometallurgical Recovery of Copper by the Use of Iodine.—ARTURO A. OSSA, of Valparaiso, Chile, has invented a process for the recovery of copper from copper-bearing minerals with the simultaneous production of sulphuric acid. The process steps constitute a closed operating cycle in which iodine is an essential and recoverable reagent, being based primarily upon the inter-reactions between solutions of copper sulphate and hydriodic acid in the presence of sulphurous acid. In this reaction a precipitate of cuprous iodide is formed and sulphuric acid set free. The iodine is eventually recovered in a form for reuse in the process and the sulphuric acid is available for leaching oxidized copper ores for the preparation of additional copper sulphate. The sulphur dioxide is ultimately oxidized to sulphuric acid and is also available for leaching. The operation comprises three principal steps:

1. Preparation of hydriodic acid solution. This is conveniently effected by suspending pulverized iodine in water in a closed tank and subjecting it to a current of sulphur dioxide; or a mixture of iodine vapor and sulphur dioxide may be passed upward through a tower filled with inert material and sprayed with water. The reaction is as follows:

2. Precipitation of cuprous iodide. A solution of copper sulphate, preferably concentrated, is saturated with sulphur dioxide in order to prevent the precipitation of iodine during the subsequent reaction. Sufficient hydriodic acid prepared as described is added to completely precipitate cuprous iodide. The reaction is as follows:

3. The regeneration of the iodine. The precipitate of cuprous iodide is removed by filtration, washed and then dried by gentle heating. The dried precipitate is mixed with approximately 20 per cent by weight of cupric oxide and the mixture calcined in a closed furnace under oxidizing conditions. The cuprous iodide is transformed into cupric oxide and the iodine set free. The reaction is as follows:

The liberated iodine sublimes and is treated for the regeneration of hydriodic acid solution. (1,343,153; June 8, 1920.)

Recovery of Copper From Oxidized Ores.—Oxidized ores of copper are not ordinarily amenable to flotation, and the presence of oxidized minerals in sulphide ores prevent the flotation of a portion of the sulphide particles. Sulphide copper minerals are not soluble in ordinary solvents such as sulphuric acid; on the other hand most oxidized copper minerals are soluble in this reagent.

W. E. GREENAWALT, of Denver, Col., takes advantage of these facts in working out a process for the recovery of copper from ores containing both oxidized and sulphide minerals, of which there are large deposits in the Western states. The ore is pulverized and treated with a dilute solution of sulphuric acid in amount sufficient to dissolve the oxidized copper. The acid pulp in which the sulphides are practically unaffected and

the oxides partly or totally converted into sulphate is agitated with flotation oil and the mixture introduced into an electrolytic cell in which it is subjected to electrolysis and flotation. The gas generated by electrolysis assists in floating the sulphide minerals and by using a high current density a non-adherent copper deposit is obtained on the cathodes; this is floated with the sulphide particles. During electrolysis sulphuric acid will be regenerated dissolving more copper and the ferric salts which are formed will be reduced by the action of the minerals in the pulp. (1,344,127; June 22, 1920.)

Potash Recovery by Metathetical Reactions.—Potash is widely distributed in combination with silica in igneous rocks such as granite, gneiss, feldspar, green-sand and leucite, but is recovered with difficulty from such materials, and at an expense inadmissible for use as commercial fertilizers. A common method consists of fusion with relatively expensive chemicals. Such a method is expensive and difficult to conduct mechanically.

ARTHUR C. SPENCER proposes to utilize the mass action principle for the recovery of potash from potash bearing rocks by treating them with a solution of salt in excess of the potash equivalent in the material, utilizing heat and pressure to hasten the reaction, having found that the substitution of the potassium in the rock by the sodium in the salt proceeds quite readily in aqueous solution at temperatures corresponding to 150 to 300 lb. steam pressure. For instance, heating glassy basalt with a solution of sodium chloride in amount and strength so that somewhat more than two equivalents of sodium are present in the zone of reaction for each equivalent of potassium in the mineral for six hours at 200 deg. C. will result in the substitution of practically all of the potassium in the mineral. It is desirable that the rock be of an amorphous variety, otherwise it is better to heat the material sufficiently to destroy the normal molecular or the crystalline structure, or both.

Certain advantages arise by the use of ammonium chloride and ammonia to bring about the reaction: the reaction proceeds at a lower temperature and a smaller amount of ammonium chloride need be employed, only a small excess over the amount equivalent to the extractable bases being required; the unconsumed ammonia is easily recovered and the excess of ammonium chloride may be decomposed by lime; the amount of water employed can also be greatly reduced. Crude ammonia salts can be used, such as byproducts from coke-oven flues, forming an outlet for the material, which does not require such fixation reagents as sulphuric acid. The ammonia will be fixed in the mineral matter as a result of the metathetical reaction. This can be recovered by heating or the material may be used as a fertilizer. The potash recovered from the solution can be added to this material, which then requires but the addition of phosphate in some form to make a complete fertilizer.

Sodium carbonate or bicarbonate can be used if the escape of carbon dioxide be prevented, and it is possible to use natural brines. In this way such brines, if they contain small amounts of potash, may be enriched. (1,344,830; June 29, 1920.)

Devulcanizing Rubber.—CYRUS F. WILLARD, of San Diego, Cal., has developed a process for devulcanizing rubber which involves certain interesting principles of colloid chemistry. Assuming the "combined" sulphur

to be adsorbed by the rubber, the inventor treats the finely ground rubber with another emulsoid colloid solution (such as wood tar emulsified in water) which has a greater affinity than the rubber for sulphur. A sulphur solvent such as turpentine is added and the mixture boiled either in an open kettle or under pressure. Under the influence of the heat and the sulphur solvent, the "combined" sulphur is liberated from the rubber and immediately adsorbed by the tar emulsion. The latter is easily removed from the remaining devulcanized rubber by treatment with 3 per cent caustic soda solution. The whole process may be carried out in one or two steps, as desired. It is claimed that over 50 per cent of the combined sulphur is removed, so that the properties of the recovered material closely approach those of the original rubber before vulcanization. Furthermore, in the case of scrap containing fabric or fiber, devulcanization takes place without destroying the fiber, which can subsequently be separated, if desired. (1,322,077; 1,322,151; 1,322,152; Nov. 18, 1919.)

Electric Zinc Furnace.—FRANCOIS LOUVRIER, of Paimbœuf, France, proposes to produce zinc from its ores in an electric furnace, the design of which is shown in the sketch. Zinc ores are fed into the furnace through the central column 3, which is sealed to prevent the inflow of air. In passing down the column the ore is dried by the heat from the liberated zinc fumes which

pass up the annular passage 15 and out through pipe 19 to a condenser. Carbon in the form of powdered coal is fed into the annular passage from hopper 17, being retained on the circular shelves 16. The introduction of the coal dust into the reaction chamber in this manner affords the opportunity for the reduction of any carbon dioxide in the escaping gases. Six electrodes, 12, are

provided; these enter the furnace through stuffing boxes 20, also filled with powdered coal; a valve, 22, permits the feeding of the coal into the reaction chamber and the close proximity of the coal to the electrode reduces the consumption of the latter. Beneath the electrodes, 12, is an annular hearth, 5, which is electrically connected through electrode 9. A central electrode, 8, is provided. This arrangement of electrodes provides for the uniform distribution of heat through the charge. Slag and metal are tapped through spouts 6 and 7. (1,342,636; June 8, 1920.)

Potash From Silicates.—EINAR BERGUE, of Notodden, Norway, assignor to Norsk Hydro-Elektrisk Kvalstofaktieselskab of Christiania, has been granted a patent on a process for the reduction of $K_2O \cdot Al_2O_3 \cdot 6SiO_2$ to $K_2S \cdot Al_2S_3 \cdot 6SiS$, or an intermediate product by heating with sulphur vapors at about 800-1,400 deg. C. These sulpho-silicons or silicates are decomposed by water under pressure, giving soluble potash. (1,346,365; July 13, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Utilizing Slag.—Relates to the utilization of blast furnace slag in the production of bricks, blocks, tiles, slabs, door and window frames, baths, sinks, pipes, conduits, and other parts of workmen's dwellings, garages, bungalows, outbuildings, &c., also electric insulators, electric main conduits, the bed-plates of electric generators, curbing, tanks, etc. The slag is broken up, graded, and filled into molds, which are then filled with molten slag so as to bind the particles of graded slag together. The graded slag may be heated, and the molten slag may be mixed with 10 to 15 per cent of silica, lime, or other binding agent, and also metallic oxides for coloring purposes; or the metallic oxides may be applied to the inner faces of the molds. The molds may also be heated and gradually cooled for the purpose of annealing the product. Instead of using molten slag direct from the blast furnace, the molds may be filled with the graded slag mixed or not with other materials such as soda-ash, cryolite, crushed waste glass, iron silicate, etc., having a lower melting point than the slag, and afterward heated to a temperature above the melting point of the slag. A mold having a double wall may be used, the space between the walls being filled with asbestos or other heat-insulating material. Or the graded slag may be placed in an inner mold surrounded by an outer mold into which the molten slag is poured while the inner mold is simultaneously removed, so that a layer of solid slag is formed around the mass of granulated slag; also molten slag may previously or simultaneously be poured among the granulated slag so as to bind the whole together. (Br. Pat. 140,874—1919. T. F. HOARE, Bradford, Yorkshire, May 27, 1920.)

Treating Wood With Liquids.—A process for lightening the color of veneers of colored wood, in imitation of the effects produced on the same wood by the prolonged action of light so that the veneers may be used for repairing or imitating old furniture, consists in treating the wood in an acid bath, preferably nitric acid, then drying the wood at as high temperature as it will stand without charring, and finally rinsing. Rosewood and purplewood are subjected to a preliminary immersion in oxalic acid and rinsed in warm water before treatment in nitric acid. In order to lessen the visibility of the grain, the wood may be immersed in alcohol for 24 hr. previous to the acid treatment. Mixtures of nitric and hydrochloric acids should be used when reddish effects are desired. Amaranth wood is treated for about half an hour in hot water before immersion in nitric acid. (Br. Pat. 141,052—1919. P. E. SIMON, Beauvais, France, June 2, 1920.)

Decarburizing Iron and Its Alloys.—Iron and its alloys are decarburized by heating to a high temperature under oxidizing conditions, and then slowly cooling, for the purpose of increasing the magnetic permeability and reducing the hysteresis loss. A low carbon ferrosilicon, for example, with 4 per cent of silicon is heated at 1,050 deg. C. for 13 hr. in a current of air at a pressure 2 mm. of mercury, and has its carbon content reduced from 0.1 to 0.01 per cent or less. The article may be placed in contact with iron oxide during the treatment, and over-oxidation may be corrected by a further heating under slightly reducing conditions. After decarburizing, the article

may be forged or rolled and annealed. (Br. Pat. 141,348—1919. METROPOLITAN - WICKERS ELECTRICAL Co., Westminster, June 9, 1920.)

Acrolein.—Acrolein is stabilized by the addition of minute quantities of phenols, e.g. from 0.1 to 1 per cent of pyrogallol, pyrocatechol, hydroquinone, gallic acid, tannin, etc. (Br. Pat. 141,361—1919. C. MOUREU, C. DUFRAISSE, P. ROBIN and J. POUGET, all of Paris, June 9, 1920.)

Artificial Leather.—Artificial leather is made from paper, alone or combined with a textile fabric, by treating with a vegetable glue such as is obtained from bananas, or from the farina of *Colocasia esculadium*, mixed with water containing 25 per cent of glycerine, with or without the addition of isinglass, casein, gum damar or other agglutinant. The material is then air-dried and may be dyed. The material so treated may be waterproofed with a mixture containing a vegetable wax such as carnauba, mixed, for example, with paraffine wax and turpentine. A number of sheets may be superposed, and the material may be finished to give it the appearance of ordinary leather. (Br. Pat. 141,385—1919. G. MILLER, Meopham, Kent, June 9, 1920.)

Deoxidizing and Refining Aluminum and Its Alloys.—For deoxidizing and refining aluminum and its alloys, an aluminum cartridge containing potassium phosphide is first added to the metal heated above its melting point, to convert the impurities, silicon, iron and oxygen, into phosphorus compounds; then, at a higher temperature, a second aluminum cartridge, containing one of the metals of the alkaline earths or lithium, is added for the purpose of decomposing the phosphorus compounds, which burn at the expense of the alkaline earth metal, and the oxides formed float on the surface of the aluminum. (Br. Pat. 141,324—1919. A. STRASSER, Borschach, Switzerland, June 9, 1920.)

Sulphuretted Dyes.—A black dye is obtained by boiling 1:2:4 dinitrophenol with sodium sulphide solution and sulphur in the presence of phenol or cresols. (Br. Pat. 141,759—1919. H. R. VIDAL, Asnières, France, June 16, 1920.)

Monoazo Dyes.—Monoazo dyes are obtained by coupling an aromatic diazocarboxylic acid with the *n*-methyl- ω -sulphonic acid derivative of an aromatic aminocarboxylic acid (capable of being coupled and diazotized) and finally eliminating the methyl- ω -sulphonic acid group. The products are mordant dyes, dyeing wool yellow to orange shades and giving similar tints on chrome-printed cotton, and may be used as parent materials for secondary disazo dyes. Examples are given of the preparation of 4-aminoazobenzene-3:3'-dicarboxylic acid, 4-aminoazobenzene-2:3'-dicarboxylic acid, 4-aminoazobenzene-3:4'-dicarboxylic acid, and 4-aminoazobenzene-3:2'-dicarboxylic acid.

N-methyl- ω -sulphonic acid derivatives of the aminocarboxylic acids referred to are prepared by heating a solution of the sodium salt of the amino acid with sodium formaldehyde bisulphite solution. (Br. Pat. 141,643—1919. SOCIETY OF CHEMICAL INDUSTRY, Basel, Switzerland, June 16, 1920.)

Aluminates.—Sodium, barium, calcium and other alkali and alkaline-earth aluminates.—Calcium aluminate practically free from other oxides is produced by heating bauxite or other aluminum ore with lime and

carbon or silicon, aluminum or calcium carbide in an electric furnace, whereby all the foreign oxides are reduced to the metallic state. Acidic oxides, such as those of silicon and titanium, form ferrous alloys which separate at the bottom of the furnace and are suitable for use in the metallurgy of iron. In place of lime, baryta or other alkaline earth may be used. The alkaline earth aluminates are converted into alkali metal aluminates, such as sodium aluminate, $\text{Al}_2\text{O}_3\cdot\text{Na}_2\text{O}$, by treating their hot solutions with alkali metal carbonates. (Br. Pat. 141,666—1919. ROCHETTE FRÈRES, Savoy, France, June 16, 1920.)

Recovery of Volatile Solvents.—In recovering volatile solvents evaporating during the drying of india-rubber articles and the like, an absorption agent is placed in the drying chamber, and uniformly distributed over it. The agent is preferably made to flow through the chamber, and may be conducted by means of rods, threads, wires, textile fabrics and the like. The solvent is subsequently recovered by distillation or other means. (Br. Pat. 141,739—1919. H. SCHMIDT, Cologne, Germany, June 16, 1920.)

Electrolysis—Zinc and Cadmium.—A precipitate obtained by adding zinc dust, with or without a copper salt, to sulphate solutions prepared from ores containing zinc and cadmium, with or without copper and cobalt, is treated for the recovery of cadmium, zinc, and, if present, copper, in the following manner: If substantially free from cobalt, the precipitate is oxidized and leached with sufficient dilute sulphuric acid to dissolve a maximum of zinc and cadmium and a minimum of copper. From the residue the copper is recovered by smelting or otherwise. Alternatively, the precipitate, oxidation of which is guarded against, may be leached with sufficient acid to dissolve the zinc, the residue being then oxidized and further treated to dissolve the cadmium. In either case, the solution containing the cadmium is treated with zinc dust in quantity insufficient for complete precipitation of the cadmium, which is thus obtained free from zinc. In this treatment, the solution should be slightly acid and air should be excluded as much as possible; about $\frac{1}{2}$ g. of cadmium per liter should remain after precipitation. A further treatment of the solution in a second vat with excess zinc, and preferably in the presence of about $\frac{1}{2}$ g. of copper per liter, gives a zinc solution which is added to the purified ore solution, and a precipitate which can be used again in the first vat. The precipitated cadmium is roasted and dissolved in dilute sulphuric acid or spent electrolyte. Copper is removed by excess of the cadmium precipitate, metallic cadmium, or cadmium oxide, and the solution, then containing about 100 g. cadmium per liter, is electrolyzed with rotating aluminum cathodes at which the current density may be 20 amp. per sq.ft. Glue may be added to the electrolyte in the proportion of 2 lb. for each ton of cadmium produced. The deposit after removal may be melted under caustic soda and potassium cyanide. After electrolysis, the solution should contain 60 g. of acid per liter. An alternative method of separating the zinc from the cadmium consists in agitating the solution with zinc oxide or hydrate at 60 deg. C. for some time, and then cooling to 35 deg. C. so as to precipitate the zinc as basic sulphate. When the original precipitate contains cobalt, it is oxidized and leached with zinc sulphate solution or just sufficient dilute sulphuric acid to dissolve out most of the cadmium and cobalt, and the residue is then treated as in the first case.

The solution of cadmium and cobalt is treated with zinc dust as described above so as to obtain zinc-free cadmium, which is added to that obtained from the residue above mentioned, and a solution of zinc and cobalt, from which a pigment may be prepared, for instance by adding sodium carbonate and drying and heating the precipitate. (Br. Pat. 141,688—1919. ELECTROLYTIC ZINC CO. OF AUSTRALASIA PROPRIETARY, LTD., Melbourne, June 16, 1920.)

Color Photography.—In the interference method of color photography, the radio activity of the mercury, silver or other radio-active material used in conjunction with the film is supplemented "instantaneously and simultaneously with the eruption of the rays reflected by the object in the form of electricity, X-rays, light or other form of free energy so as to make up for the normal insufficiency of the radio-activity of these substances made by radiation in the opposite direction from these latter to aid, on the one hand, the extra rapid realization of the equilibrium of the stationary rays, the remainder of the available energy serving to effect the laminar formation of the different complementary colorations corresponding to the rays absorbed by the object, and on the other hand to aid in the prompt formation of the blacks by the process of superposition of unilateral rays in the region of the sensitive film where no ray comes from the object." (Br. Pat. 141,699—1919. P. ELMASSIAN, Paris, France, June 16, 1920.)

Imitation Leather.—In the manufacture of imitation leather, bundles or laps of fibers are led on to an endless conveyor band, and binding, softening and hygro-

scopic substances are applied to the fibers, which are simultaneously acted upon by a blower to produce a "felting" of the fibers. As shown, fibers 1 from a carding-machine pass over a conveyor 3 to a conveyor 2 and are subjected at 6 to the action of a blower, treated with binding, fatty, and hygroscopic substances at 7, 8, and 9 respectively, then subjected again to the action of a blower at 10, and pass between pressing-rollers 11 and calendar rollers 14 to a roll 15. For producing thicker fabric, the material is passed a number of times around the conveyor 2, or a drum, while fresh fibers are fed from the carding-machine. In another form of apparatus, a number of layers of fibers are fed simultaneously from rolls on to successive parts of an endless conveyor, the fibers of each layer being subjected to the action of a blower and treated with binding and softening or hygroscopic substances. The binding substance may be a solution of cellulose, cuprammonium oxide, glue, etc. (Br. Pat. 141,712—1919. N. ZIGNONE, Milan, Italy, June 16, 1920.)

Ammonium Sulphate.—Neutral ammonium sulphate is prepared by mixing the crystals removed from the saturator with ammonium sulphite or bisulphite, in solid form or in solution, either before or after the crystals have been washed, or by adding ammonium sulphite or bisulphite to the washing liquor. (Br. Pat. 141,799—1919. SOUTH METROPOLITAN GAS CO., London, and O. W. WEIGHT, Bromley, Kent, June 23, 1920.)

in the Chemical and Metallurgical Industries

Special Train Service to Chicago for A. C. S. Meeting

The special transportation committee of the New York Section of the American Chemical Society in charge of transportation from Eastern points to Chicago for the general meeting of the American Chemical Society, Sept. 7 to 10, finds that alternative plans can be made for a special car or cars on the New York Central and Pennsylvania lines. Members of the Society who would like to join these special parties at New York or points farther west should communicate immediately with Frank E. Dodge, care of The Barrett Co., 17 Battery Pl., New York City. Space will be reserved upon receipt of telegram or letter together with the necessary remittance.

On the New York Central a special car or cars will leave on Train No. 3, from Grand Central Station, New York City, at 8:45 a.m., Eastern standard time, Sunday, Sept. 5, arriving in Chicago Monday 7:40 a.m., Central standard time. The fares from New York and intermediate points, including extra fare, which is \$5.10 from New York, together with Pullman charges, are as follows:

City	Fare	Upper	Lower	Dr. Room	Compartment
New York City.....	\$40.46	\$7.78	\$9.72	\$34.02	\$27.54
Albany.....	31.84	7.13	8.91	32.40	25.11
Schenectady.....	31.19	7.13	8.91	32.40	25.11
Syracuse.....	26.10	5.51	6.91	24.30	19.44
Rochester.....	22.98	4.86	6.10	22.68	17.01
Buffalo.....	20.31	4.86	6.10	22.68	17.01
Cleveland.....	13.19	3.24	4.05	14.58	11.34

On the Pennsylvania a special car or cars will be attached to train No. 5, leaving Pennsylvania Station, New York City, at 11:04 a.m., Eastern standard time, Sunday, Sept. 5, arriving in Chicago Monday at 9 a.m., Central standard time. The fares, including extra fare and Pullman, are as follows:

City	Fare	Upper	Lower	Dr. Room	Compartment
New York City.....	\$41.76	\$7.78	\$9.72	\$34.02	\$27.54
Philadelphia.....	36.96	7.13	8.91	32.40	25.11
Baltimore.....	30.97	7.13	8.91	32.40	25.11
Washington.....	30.97	7.13	8.91	32.40	25.11
Harrisburg.....	27.76	6.48	8.10	29.16	22.68
Pittsburgh.....	18.23	3.89	4.86	17.62	13.77

These fares, figured from the existing tariff by the railroad passenger departments, may vary by a few cents when the official tariff is promulgated. Trains on either line will arrive in Chicago in time for the meeting of the directors and advisory committee at 12:30 p.m. and the council meeting at 4 p.m.

Alpha Chi Sigma to Meet in Chicago

The chemical fraternity Alpha Chi Sigma will hold a meeting in Chicago coincident with the meeting of the American Chemical Society in September. A banquet will be served at the Morrison Hotel at 6:30 on Wednesday evening, Sept. 8, and a business meeting will follow. Members of the fraternity are requested to register at a place provided for that purpose at the headquarters of the American Chemical Society, Congress Hotel.

Application of Government Research to Be Fostered

In announcing the appointment of David J. Price as chief of the office of development work in the Bureau of Chemistry, Dr. C. I. Alsberg, chief of that Bureau, makes the following statement:

The practical application in the industries and in the arts of scientific research is quite a different matter from the doing of the research itself. It requires rather different talents and an objective point of view which the scientist in his enthusiasm may not always have. If it be a matter involving manufacturing, for example, it requires the calculation of costs, which is really usually an engineering problem, and which in many cases can best be done by someone without the bias of authorship. In short, it is rather an engineering business problem than a problem of science.

It is expected that the work to be undertaken along these lines by Mr. Price will afford both the industries and the investigators of the Bureau added facility for co-operation in the application of research conclusions that have possible industrial value. It is hoped that any industry finding valuable conclusions in the work will thus be aided to a prompt realization of the technical possibilities from an engineering as well as a laboratory point of view.

Another important aspect of this is also emphasized by Dr. Alsberg when he says: "I believe that by such an arrangement as is proposed herein much of the Bureau's work can be made effective and that the investigators of the Bureau may be made free to prosecute their researches and not waste unnecessary time in establishing industrial contacts."

It has not yet been determined what particular problems will first be attacked by this new office, but the work will go forward early in the fall.

Water-Power Rules and Regulations

The rules and regulations to be used in connection with the administration of the water-power act are being perfected. The regulations were the subject of two public hearings, at which the draft was criticized and suggestions made. The committee of the Federal Power Commission, together with a committee representing outside interests, is working out the moot points in order that the regulations may be promulgated in the near future.

The financial interests made an especially urgent plea that in framing the regulations, sight should not be lost of the fact that, at best, it is going to be difficult to interest capital, under present conditions.

Bureau of Mines Creates New Division

F. G. Cottrell, director of the Bureau of Mines, has authorized the creation of a division on non-ferrous metallurgy. A. E. Wells, who has been a member of the Bureau's staff for many years, will be in charge of the new division with the title of chief metallurgical engineer. The headquarters of the division will be maintained in Salt Lake City.

October Meeting Electric Furnace Association

The subject of Refractories has been selected for the session of the Electric Furnace Association which will be held in Columbus on Wednesday afternoon, Oct. 6.

The meeting will provide an opportunity for a discussion of their problems by the users and makers of refractories. Papers will be presented by steel men and by the manufacturers of bricks and lining materials, and considerable time will be allowed for questions and informal discussion.

Some other interesting features are being arranged for the meeting so that it should be a considerable addition to the progress of activities already planned for the first week of October in Columbus.

The Electric Furnace Association plans to hold its session in one of the buildings of the Ohio State University.

The British Paper Industry

British paper makers are making extensive plans to meet the ever-increasing demand for paper. Because of the uncertainty of business due to war conditions and the lack of raw materials, all previous measures had to be delayed till a more propitious time. Conditions, however, have very much improved since the armistice and the companies are fast recovering from the effects of the war.

The Imperial Paper Mills, Incorporated, is offering to investors £800,000 of 7½ guaranteed 15-year first mortgage debenture stock at 93 and redeemable at 103. This stock is secured by a first mortgage on mills and property at Gravesend on the Thames and on shares of a Canadian company.

The Imperial Mills was organized to supply the requirements of the Amalgamated Press, Ltd., in the production of its seventy periodicals and magazines and also the large amount of paper necessary for the printing of the *Times*, the *Daily Mail*, the *Daily Mirror*, the *Sunday Pictorial* and other papers. Originally the mills were designed with a weekly capacity of 1,500 tons. This output, however, is to be increased to 1,800 tons per week in the new plants.

CANADIAN PULP MILLS PURCHASED

The Imperial Co., together with Lord Rothermere and companies with which he is associated, has recently purchased the whole of the capital stock of the pulp mills of the Gulf Pulp & Paper Co. at Clarke City, in the Province of Quebec, on the St. Lawrence River, together with timber limits of about 625,000 acres. Under the arrangements for purchase, the Imperial Co. will acquire two-thirds of the capital, the other third being taken by outside interest.

The businesses of Edward Collins & Sons of Glasgow and Henry Leigh Slater of Manchester have been consolidated in the incorporation of the Amalgamated Paper Mills, Ltd., with a share capital of £900,000 issued at par, £400,000 of which is 8 per cent cumulative participating preferred shares.

The Kelvindale mills of Edward Collins & Sons are among the oldest paper-making concerns in the United Kingdom, having been established in 1746. The average output of the two concerns is 190 tons per week. Recently the Slater Co., in association with M. A. Berges of the Papeteries Berges (Paris), formed a new company, the Société Franco-Anglaise des Papiers Speciaux, which is erecting a new plant at Eragny, near

Paris, for the purpose of coating the papers manufactured by the Berges Co.

The profits of the Collins and Slater firms combined advanced from £86,797 in 1916 to £220,219 in 1918, but dropped to £56,791 in 1919, due to war conditions. Profits for this year are estimated at the rate of £294,803 per annum.

Although only a few of the companies publish public reports, those of the following large companies will give some idea of the profits made in this industry.

PROFITS AFTER PROVIDING FOR EXCESS PROFIT DUTY

	1919	1918	1917
Edward Lloyd.....	£223,032	£117,940	£151,536
Ordinary dividend.....	13½%	11½%	11½%
Alex Pirie & Sons.....	£105,543	£102,500	£83,833
Ordinary dividend.....	6%	%	6%
C. Marsden & Sons.....	£97,930	£66,180	£26,884
Ordinary dividend.....	9%	8½%	6%
A. M. Peebles & Son.....	£43,287	£38,349	£21,102
Ordinary dividend.....	9%	5%
A. E. Reed & Co.....	£135,485	£111,295	£73,308
Ordinary dividend.....	14%	10%	10%
Spier Brothers.....	£236,500	£155,584	£155,345
Ordinary dividend.....	14%	12½%	12½%

PROTECTIVE AGREEMENTS

Compared with Germany, where there were several cartels, the British paper industry is almost without organization. Every individual firm moved along in its own way. It was only under stress of war that the British makers made price agreements among themselves. Fear of foreign competition has also caused a suggestion that a duty of 15 per cent be imposed on all imports to protect home industries.

RAW MATERIALS

The shortage of raw material is gradually becoming less acute and more stock is coming in. In the first half of the current year (January to June) the import of pulp wood, grass, rags, etc., exceeded 600,000 gross tons, compared with the import of the corresponding period of 380,000 tons and a pre-war total of 563,758 tons. The net import of pulpwood, the chief raw material, for the last six months amounted to 505,195 tons, esparto, rags, etc., amounting to only 94,830 tons, with a total aggregate value of £14,403,831.

FOREIGN TRADE

England is still importing from abroad immense quantities of manufactured paper of all kinds, the aggregate of the six months being 346,047 gross tons, as compared with 303,638 tons in the same period during 1913. Although the imports are large, England's exports of paper manufactured in the United Kingdom made a poor showing, the total for the six months period being only 48,489 gross tons. It is this extraordinary excess of imports of foreign-made paper over the comparatively small quantity of British exports that causes the paper manufacturers anxiety. Norway and Sweden furnished England with 45 per cent of its printing and writing paper during the last half year, and 75 per cent of packing and wrapping paper, including tissue paper.

The reappearance of Germany as an exporter of approximately 8,000 tons is an interesting item. Russia exported to Great Britain 13,110 tons of packing and wrapping paper. Imports of straw board amounted to 105,900 tons and came mostly from Holland. The United States supplied England with a little more than 2,000 tons.

Corn Products Refining Co. to Build Big Factory in Kansas City

Approximately \$8,000,000 will be required for an extensive manufacturing enterprise to be established here by the Corn Products Refining Co., of Chicago, New York and other cities.

The amount will be expended for branch works manufacturing sirup and various other products from corn. Seventy-five acres of land have been bought for the site and engineers are preparing plans for buildings, the construction of which will begin in September. There will be seven large buildings, all of reinforced concrete construction, the largest to have about 100,000 sq.ft. of floor space.

The manufacturing machinery to be installed will consume each day about 25,000 bu. of corn and 10,000,000 gal. pure water from an artesian well. About 1,000 operatives will be employed, most of the machinery being automatic. Prominent officials of the corporation expect to profit considerably by the increasing use of the Missouri River for the transportation of freight. Large quantities of corn are imported from the Argentine Republic by the Corn Products Refining Co. and this supply may in time come up the Missouri River when this ship transportation for the lower Missouri has been assured.

Maritime Chemists Association Holds Annual Meeting

The annual meeting of the Maritime Chemists Association was held on Aug. 3 in St. John, N. B. The chief business of general interest transacted was the formation of a Maritime Section of the Society of Chemical Industry which will function as a separate section of the Society. The program also included among others an illustrated address by H. Jermaine Creighton, D. C. S., of Swarthmore College, Pa., in "How the Nitrogen Problem Has Been Solved," and an interesting paper by Prof. H. C. Hanlon on the newly discovered salt deposits at Malagash, N. S.

Officers elected for the ensuing year were:

President, Dr. H. S. Biglow, Mt. Allison University.

Vice-presidents, Dr. H. Jermaine Creighton, Swarthmore College; I. C. Mackie, Dominion Iron & Steel Co.

Executive, Prof. H. C. Hanlon, N. S. Agricultural College; A. F. Blake, Atlantic Sugar & Refining, Ltd.

Secretary and treasurer, H. B. Vickery, Provincial Normal College.

Lack of Coal a Menace to Paper Supply

President Dodge of International Paper Co. says the Commerce Commission must modify its priority orders in allocating coal and wood cars or many newspapers will have to suspend publication because production and shipment of print paper must cease. He says over 400 newspapers of United States, directly dependent on company for their stock, are now "living from hand to mouth."

Manganese in Southern Nevada

More than twenty-five manganese mines and prospects in the southwestern part of Nevada are described in Bulletin 710F of the U. S. Geological Survey. The average content of Mn is reported as about 40 per cent. The total estimated amount of Mn runs into many hundreds of thousands of tons. The limiting factors are found in transportation and cost of production.

Milk Plants in Washington

Utility plants costing approximately \$600,000, capable of handling 500,000 lb. of milk daily, with an annual output of an estimated value of \$8,000,000, are being constructed by United Dairy Associations of Washington in Seattle, Wash. These plants will manufacture the raw milk into butter, milk powder, ice cream and cheese.

One of the new plants to be constructed at Lynlen will cost \$150,000 and will handle 100,000 lb. of milk daily. Skagit County dairymen are building a \$250,000 plant at Burlington with a daily capacity of 250,000 lb. of milk. Snohomish County dairymen purchased a modern condenser plant.

Besides these projects the dairymen in Grays Harbor County have at Satsop what is said to be the largest cheese factory in this country, if not in the world. Its output is 3,000 lb. every day in the year.

Products of these plants will be standardized, so that large orders can be filled from products of all the plants.

Dyes or Dyestuffs?

A laboratory for research on dyestuffs and explosives has been established at George Washington University, Washington, D. C. It is to be under the general supervision of Prof. H. C. McNeil and in charge of G. W. Phillips, formerly of the C. W. S. Prof. C. E. Munroe of the National Research Council will be consulting chemist of the laboratory.

Why do they call dyes "dyestuffs"? Dyes is a good old English word that means exactly the same thing. We might as well say colorstuffs. We are glad to see the laboratory established, our only objection is to its German name. The word dyestuffs indicates bulk and weight rather than tinctorial power. Dyes is better.

Glass Works for Birmingham

General glass products in the nature of bottles will be manufactured in Birmingham, Ala., in a \$400,000 plant to be built by the Birmingham Glass Manufacturing Co., a new enterprise organized by New York and Alabama capitalists, who have secured a site and land containing several million tons of silica sand. The officers named for the first year are Sol W. Quinn, president; H. C. Bryson, vice-president, both of New York, and E. R. Owen, secretary, of Birmingham, Ala.

Use of Glycol as a Substitute for Glycerol

It is proposed in *Der Scifenfabrikant* (vol. 40, pp. 245-6, 1920) by H. Wolff of Berlin that glycol be used in the place of glycerol as a substitute owing to its hygroscopic and viscous nature. It is used to advantage, he says, for printing inks, for softening, cleaning and felting textiles and in pharmacy. Schlinck & Co. has patented its use (Ger. Pat. 315,222) to neutralize the acidity of oils by boiling them with glycol under reflux in order to convert the free acids into glycol esters.

New Lignite Carbonization Research Plant in North Dakota

The sum of \$200,000 has been subscribed by private persons to build and operate a research plant for the carbonization of lignite at New Salem, N. D. It will be conducted by the staff of the U. S. Bureau of Mines.

The Chemistry of Churning Butter

L. S. Palmer of the Missouri Agricultural Experiment Station has made a study of the chemistry of churning butter. As the stage of lactation advances the protein concentration of the milk increases, while the size of the fat globules decreases. Therefore the difficulty in churning increases, and this factor is beyond the complete control of the butter maker. His microscopic work gave strong support to Fischer's idea that the formation of butter consists in a change of fat-in-colloid-hydrate emulsion (cream) into a colloid-hydrate-in-fat emulsion, which is butter.

June Exports and Imports of Dyes and Dyestuffs

Payne Hears War Mineral Plea

After listening to arguments of representatives of the Mining Congress and attorneys for claimants under the war minerals relief act, the Secretary of the Interior has stated that he has no objection to the enactment by Congress of a law giving to these claimants the right to appeal their cases to the United States Court of Appeals.

Manufacture of Paper Pulp in Congo

Papyrus, which grows in great abundance near Elizabethville, in the Belgian Congo, principally along the lower Lualaba, near the lakes of Kabuli, Sjemba, Kisali and Neaga, is to be exploited by a large company which has been granted a concession. It is planned to establish near the river a large plant, costing two and a half million francs, which will have an initial production of 20,000 tons of pulp. The material for this factory is to be sought among Belgian and, if necessary, allied manufacturers.

The papyrus of the Congo has proved on analysis to contain 37.8 per cent cellulose. After research and experiments, a process was discovered for bleaching the plants which had been vainly sought for fifty years.

Personal

Dr. JOHN J. ABEL, professor of pharmacology at the Johns Hopkins Medical School, Baltimore, Md., has received an honorary doctorate of laws from Cambridge University. Dr. Abel's numerous and distinguished researches on the chemistry of animal tissues and fluids and on the physiological and therapeutic action of various substances render him worthy of academic distinction.

Dr. H. K. BENSON, in charge of the chemistry department of the University of Washington, is spending the summer at Lake Bunsen, B. C., conducting special research work for the American Nitrogen Products Co. Dr. Benson will return to Seattle in September.

A. W. FAHRENWALD has been appointed ore-dressing engineer with the U. S. Bureau of Mines in charge of the station at Moscow, Idaho.

CHARLES H. FULTON, formerly professor of metallurgy in the Case School of Applied Science, has been appointed

director of the School of Mines and Metallurgy, University of Missouri, Rolla, Mo., and not head of the Mining Department as given erroneously in our issue of Aug. 4. Prof. Forbes is head of the Mining Department.

H. S. GALE, who for many years has been the Geological Survey's specialist on potash and nitrate, has resigned to enter private employment.

RALPH A. GOULD and BRYANT S. DRAKE announce their association, from Aug. 1, as a partnership under the firm name of Gould & Drake, chemical engineers, with offices at 216 Pine St., San Francisco, Cal.

CHARLES S. HOWARD, formerly an instructor in the department of electrical engineering and physics at the U. S. Naval Academy, has accepted a position as junior chemist in the Quality of Water Division of the Water Resources Branch of the U. S. Geological Survey, Washington, D. C.

ERIC A. LOF has just returned from Europe, where he visited a large number of industrial plants in Sweden, Norway, England, France and Belgium.

Dr. VAN H. MANNING, director of research of the American Petroleum Institute, has returned from a trip to Europe.

E. P. MATHEWSON has gone to Arizona on a professional engagement.

PAUL MOORE, at present director of the Information Bureau of the War Trade Board, will become the secretary of the Division of Research Extension, National Research Council, on or about Oct. 1. Mr. Moore will devote himself to the promotion of research with particular reference to the industries. In this work he will be associated with Dr. H. E. Howe, who continues actively in this field as the chairman of this division of the Council.

Prof. ARTHUR M. PARDEE has resigned from the chair of chemistry at Washington and Jefferson College, Washington, Pa., to become the head of the department and professor of chemistry at the University of South Dakota, Vermillion, S. D.

Dr. CHARLES L. PARSONS, secretary of the American Chemical Society, has returned to Washington following the adjournment of the International Union of Pure and Applied Chemistry at Rome, where he acted as the American representative.

JOHN H. RAMAGE, formerly metallurgist, industrial department, U. S. Navy Yard, Norfolk, Va., is now metallurgist for the Westinghouse Lamp Co., Bloomfield, N. J.

RICHARD R. REES has resigned as chief metallurgist at U. S. Arsenal, Watervliet, N. Y., to accept a position as metallurgist with the Neptune Meter Co., Long Island City, N. Y.

R. T. READ, of the safety department of E. I. du Pont de Nemours & Co., has been appointed by the National Safety Council as permanent secretary of the Delaware local council.

J. C. TOWNSEND, formerly safety engineer for the International Shoe Co., of St. Louis, has been appointed by the National Safety Council manager of the Grand Rapids division.

Obituary

Dr. E. Y. TITUS, a member of the technical staff of the International Coal Products Co., Newark, N. J., died on Aug. 7, as a result of blood poisoning following an accident in which he was run down by an automobile. Dr. Titus was formerly associate professor of physical chemistry at the University of Wisconsin; later chief chemist at U. S. Nitrate Plant No. 1, Muscle Shoals, Ala., and prior to his engagement with the International Coal Products Co. he was in the U. S. Fixed Nitrogen Research Laboratory. He had been married about a month at the time of his death.

Book Reviews

IRON AND STEEL. By Erik Oberg and Franklin D. Jones, editor and associate editor of *Machinery*, in collaboration with prominent metallurgists and steel-makers. 328 pp. New York: The Industrial Press.

In the rather limited space of 300 pages of pica type, the authors present "A Treatise on the Smelting, Refining, and Mechanical Processes of the Iron and Steel Industry, Including the Chemical and Physical Characteristics of Wrought Iron, Carbon, High-Speed and Alloy Steels, Cast Iron, and Steel Castings, and the Application of These Materials in Machine and Tool Construction." Obviously the words "brief outline" would be better than "treatise." Thus in the very sub-title the authors exhibit that defect of non-precise diction which will blast their hopes that their volume will find favor as a text-book for technical students. The casual reader may not mind, but the budding engineer or technician should not be told that "wrought iron" and "bushelled scrap" are the same thing (p. 72) nor think of "ingot iron" and "wrought iron" as the same type of material (p. 79).

It is too bad that the prominent metallurgists collaborating in this work did not revise the chemical terminology. When discussing bessemer steel (p. 139) it is said that "the graphitic carbon is burned into the combined form," whatever that action may consist in. Also on page 140 the statement is made that "manganese . . . burns the sulphur (which is in the form of iron sulphide) into manganese sulphide." At the bottom of page 147 is a simple explanation of rephosphorization in acid steel which will attract those metallurgists who are delving into the mysteries of balanced reactions for light.

Had the authors confined themselves to the mechanical processes involved in the manufacture of steel products, a happier result would undoubtedly have been attained. Their chapter on Rolling and Drawing contains an unusually full and well-illustrated account of the operations involved in the cold drawing and rolling of shafting, strip and wire. Forty pages are devoted to this matter, a disproportionate amount in a general survey, but fortunately so in this case. Doubtless by experience and intimate contact the authors could have presented an authoritative yet concise account of non-metallurgical operations in modern steel mills which have filled a vacant spot in American technical literature, rather than merely another book, of which there are already far too many. E. E. THUM.

Current Market Reports

The Iron and Steel Market

Pittsburgh, August 20, 1920.

The iron and steel market has not established any general or definite trend, but rather is displaying even more confusing features than a few weeks ago. For instance, semi-finished steel prices are showing a distinct downward trend and pig iron is not merely showing an advancing tendency, it actually has advanced, and in the case of valley foundry iron by no less than \$4 a ton in a week. The influence of improving transportation conditions is not defined. There does not seem to be any increased consumptive demand for steel in consequence, while there are heavier deliveries of steel, yet this does not seem to make steel more plentiful.

IMPROVED TRANSPORTATION

The improvement in transportation, as regards the movement of steel products, has been continuous for several weeks. Taking the steel industry as a whole, the rate of

accumulating of steel began to decrease several weeks ago, while the increase in shipments has proceeded far enough so that no more steel is accumulating, the present situation being that while some mills have added to their accumulations in the past week or two others have moved some of the steel accumulated many weeks ago.

Hopes had been entertained that the Interstate Commerce Commission would allow the coal-car preference order to expire Aug. 19, at the end of its two 30-day periods, thus releasing many flat-bottom gondolas from coal movement to pig iron and steel movement, but the commission has extended the order for another thirty days, to Sept. 18, and has not relaxed the provision that gondolas 38 in. and higher inside measurement are to be considered coal cars. Apart from this, the Pennsylvania system has made an order on its own account that cars classifiable as coal cars may no longer be loaded with other freight when destined to travel toward the coal mine, and thus shipments of some valley producers to the Pittsburgh district are impeded. On the whole, however, car supplies at furnaces and mills are increased by reason of there being a more rapid movement of cars all around, the total quantity of transportation having increased. The point has not yet been reached at which coal mines are able to load all the cars furnished, but that time may come soon, and then some cars would automatically be released for use by the iron and steel and other industries.

A noteworthy improvement in transportation is seen in connection with placement of cars for coke loading in the Connellsville region. For several months the production there has been regulated by the car supply. The Connellsville *Courier* reports production of coke in the Connellsville and lower Connellsville region in the past three weeks as having been as follows, successively: 172,870 tons, 194,140 tons, 219,440 tons. A labor shortage has not yet been uncovered in the region, although a continuation of increasing car supplies would eventually make labor the limiting factor. The better car placements are due solely or chiefly to quicker movement of the cars that have been in the coke service right along. The quantity of coke en route to furnaces has been reduced, and thus the receipts have increased even more than the shipments.

ADVANCING PIG IRON

The advances in pig iron are rather a curious phenomenon, considering the fact that any trend observable in steel products is downward, while pig iron was already too high relative to steel prices. The buying of pig iron is not heavy, but it is so insistent that when furnaces ask higher prices enough consumers pay the advance to establish the market at the higher figures. In the past week sales have established foundry pig iron, valley furnaces, at a \$4 advance, while transactions in steel-making grades have scarcely been sufficient, with conservative market reporting, to establish higher levels distinctly. In foundry iron the transactions, though totaling only a few thousand tons, have established \$50 valley as the market, a few of the sales being for delivery to the end of the year. Former quotations were: bessemer, \$47; basic, \$46.50; foundry, \$46. If foundry iron does not recede from \$50 it is quite probable that within a few days the other grades will be clearly established at a \$50 level. As the market has never before advanced even by a dollar or two on such light transactions, there are naturally misgivings in some quarters as to what the end of this curious movement will be.

SEMI-FINISHED STEEL

It is learned that in a number of recent transactions in sheet bars \$70 Pittsburgh was shaded slightly, and this figure represents absolutely the top of the market, though three weeks ago the market seemed clearly established at \$75 as minimum. There are reports of a number of transactions in standard billets, particularly in the East, on the basis of \$60 Pittsburgh. Obviously \$50 pig iron and \$60 billets are not properly aligned. Again, however, bars and shapes can be bought for forward delivery at about 3c., or \$60 a net ton, and this does not agree with \$60 per gross ton for billets.

Many statements are now being made that the decline in automobile building is not as great as has been reported in some quarters, and it seems evident that there is a good bit to explain away, if possible. The steel industry feels much less pressure from the majority of automobile factories for steel deliveries, but the loss in tonnage is a small item compared with the total steel productive capacity, since at capacity for both industries the automobile industry would not absorb more than 6 or 7 per cent at the outside of all the steel. In such items as hot and cold rolled strips, however, the decrease in demand is important.

As to railroad buying, it is quite improbable that there will be any buying of cars and locomotives to amount to anything for delivery before early next year. Car and locomotive repair work will continue and will absorb considerable tonnages of steel. A little interest is beginning to be shown in rails for next year.

In steel for large construction jobs there is very little demand and it does not look as though there would be much activity along this line until some changes occur in fundamental conditions.

The general demand for steel, for a wide variety of uses, continues good and it remains the marvel of the trade that so much steel can be absorbed when there do not appear to be heavy consumptive operations in progress.

The Chemical and Allied Industrial Markets

New York, August 20, 1920.

Considering the season of the year, there has been considerable price activity during the week. The movement in general has been upward, with a noticeably firmer undertone to the market, although the volume of business transacted does not seem to be very much more than the usual amount. The increases, where they have occurred, have been made by producers who are finding it impossible to meet existing prices with the increased labor costs and transportation difficulties.

Among the items that came up is *calcium chloride*, fused lump, formerly listed at \$25@30 per ton as low price and now difficult to obtain under \$33. With it the *granulated* grade also advanced to a low mark of 2@2½c. per lb. The average price for *formaldehyde* is between 40@50c. per lb., although it is possible to get small lots of from one to five tons at a figure slightly under the market, from second hands who are finding it difficult to find purchasers at 40c.

The newly arranged schedule of prices on *sal soda* issued by producers ranges between \$2@2.25 per cwt.; this represents an increase of 75c. per cwt. and is evidently due to the increased cost of production and is also a move in preparation for the coming buying season. In comparison with the rise of *sal soda* is the sharp decrease of *caustic soda*, which is down as low as \$5.60, against recent quotations of \$6.25@7 per cwt. There is no doubt the demand for this item has greatly fallen off and with the banks calling in notes holders are making concessions to get rid of the material on hand.

COAL-TAR PRODUCTS

The absence of buying interests is felt in the coal-tar products market and prices are at about the same levels as previously reported. Both *aniline oil* and *salts* have fallen off, the former being listed at 30@33c. and the latter at 35@40c. per lb., with very little activity displayed. *Benzidine sulphate* has also been affected and current quotations are 85@90c., against the recent 90c.@1 per lb. level. In contrast with these comparatively small drops, *dimethylaniline* came down from \$1.35@1.45 to \$1@1.05 per lb. The looked-for increased interest caused by the expected return of textile mills to their former activity has not strengthened this market to any extent and whereas the drops are not numerous there is not one actual increase in the list.

Ortho-toluidine and *paranitraniline* are both slightly under last week's listing, the former being quoted at 30@35c. and the latter \$1.10@1.20 per lb., representing a drop of 25c. per lb. for this material.

In line with the other allied markets the *waxes* continue weak, as demand is practically at a standstill. Through a mistake in the price table of the Aug. 18 issue, *Carnauba*, No. 2, regular, was quoted at 55@60c. per lb., whereas the correct price is 85@86c., a 5c. difference between that and No. 1, which is now being sold around 90@95c. per lb. *Montan*, crude, is weaker at 25@26c. than it was last week and business has been very dull as a result.

VEGETABLE OILS

	Today	Week Ago	Month Ago	Year Ago
Cottonseed oil, crude.....	\$0.10	\$0.10@.11	\$0.11	\$0.22
Cottonseed oil, summer yellow....	.12	.13@.13	.18	.27
Cottonseed oil, winter yellow.....	.17	.18	.21	.27

The above table shows the decline in cottonseed oil during the past year. The principal reason back of this downward movement is the persistent lack of demand on the part of consumers, with a resulting accumulation of supplies in the hands of the crushers. To remedy this situation the farmer is being urged to withhold his supply of seed, thereby causing a scarcity on the market of this commodity and boosting the price back to former war levels. The present price is the lowest it has ever been since this commodity had its first sensational rise immediately after being introduced on the market, when the crude could be obtained for 5@6c. per lb. Previously it had been thrown away as useless until the discovery was made that it could be used in cattle feeding and as a fertilizer. During the war the peak was reached when it sold as high as 24c. per lb., but since then owing to slackening of demand the price has been steadily falling off.

MISCELLANEOUS MATERIALS

Feldspar remains very scarce and \$17@20 is the nominal quotation, although all contracts are being written with a provisional clause making the price subject to "prevailing quotation at time of shipment." All grades of *shellac* have strengthened and although it is possible to obtain small quantities of this material slightly under the current quotations, it would be only the cheaper grades on which concessions would be granted. The fall crop, while there is no surplus, promises to meet requirements, and with the present heavy inquiry it is expected these prices will prevail for some time.

The St. Louis Market

St. Louis, Mo., August 17, 1920.

The chemical market for this district continues quiet and prices remain firm. With the settlement of the railroad rates and wages many large buyers are coming into the market for future needs and producers are booking orders for 1921 delivery. An increase in prices for nearly all lines is predicted in the near future, as the increase in freight rates will in many cases materially affect the cost of raw materials.

The local supply of chemicals is now normal and ample to meet present demands, with the following quotations, based on car lots unless otherwise noted, holding firm. The market for *sulphuric acid* continues good with prices unchanged. The 60 deg. grade is quoted at \$16 per ton and 66 deg. at \$24 per ton. *Oleum* remains unchanged at \$27.50 per ton.

Muriatic acid is quiet and prices unchanged at \$25 per ton and 2@2½c. per lb. in carboys.

The supply of *sodium bisulphate* is now ample and prices are quoted at from \$5 to \$6 per ton, a slight reduction from previous quotations.

Nitric acid remains unchanged and is quoted at \$7 per cwt. for the 36 deg. and \$10 per cwt. for the 42 deg. *Standard mixed acid*, consisting of 36 deg. nitric and 61 deg. sulphuric, is unchanged at 11½c. per lb. of nitric and 1½c. per lb. of sulphuric acid.

Zinc chloride, 50 per cent solution, is quoted at \$4 per cwt., an increase of 25c. due to rise in cost of raw material.

Phenol is plentiful due to a local firm disposing of surplus Government stocks, and prices are unchanged at 12c. per lb. in lots of fifteen tons or more.

Beta naphthol, sublimed (nominal).....lb.
Beta naphthol, tech (nominal).....lb.	85 -	95
Beta naphthylamine, sublimed.....lb.	2.25 -	2.40
Cresol, U. S. P., in drums (100 lb).....lb.	18 -	19
Ortho-cresol, in drums (100 lb).....lb.	23 -	25
Creosylic acid, 97-99%, straw color, in drums.....gal	1.05 -	1.15
Creosylic acid, 95-97%, dark, in drums.....gal	1.00 -	1.05
Creosylic acid, 50%, first quality, drums.....gal	65 -	75
Dichlorobenzol.....lb.	08 -	10
Diethylaniline.....lb.	1.50 -	1.60
Dimethylaniline.....lb.	1.07 -	1.05
Dinitrobenzol.....lb.	30 -	37
Dinitrochlorobenzol.....lb.	32 -	35
Dinitronaphthalene.....lb.	45 -	55
Dinitrophenol.....lb.	40 -	45
Dinitrotoluenol.....lb.	40
Dip oil, 25%, tar acids, car lots, in drums.....gal	38 -	40
Diphenylamine (nominal).....lb.	80 -	85
H-acid (nominal).....lb.	2.00 -	2.25
Metaphenylenediamine.....lb.	1.25 -	1.30
Monochlorobenzol.....lb.	18 -	20
Monothylaniline.....lb.	2.00 -	2.40
Naphthalene crushed, in bbls. (250 lb).....lb.
Naphthalene, flake.....lb.	19
Naphthalene, balls.....lb.	19
Naphthionic acid, crude.....lb.	75 -	85
Nitrobenzol.....lb.	14 -	19
Nitro-naphthalene.....lb.	40 -	50
Nitro-toluenol.....lb.	18 -	25
Ortho-amidophenol.....lb.	3.25 -	4.25
Ortho-dichlor-benzol.....lb.	15 -	20
Ortho-nitro-phenol.....lb.	80 -	85
Ortho-nitro-to.....lb.	25 -	30
Ortho-toluidine.....lb.	35 -	40
Para-amidophenol, base.....lb.	2.50 -	3.00
Para-amidophenol, HCl.....lb.	2.50 -	3.00
Para-dichlor-benzol.....lb.	08 -	12
Paranitraniline.....lb.	1.10 -	1.20

Parn-nitro-toluenol.....lb.	1.35 -	1.50
Paraphenylenediamine.....lb.	2.50 -	2.65
Paratoluidine.....lb.	2.00 -	2.25
Phthalic anhydride.....lb.	60 -	70
Phenol, U. S. P., drums (deat.), (240 lb).....lb.	12 -	12
Pyridin.....gal.	2.00 -	3.50
Resorcin, technical.....lb.	4.25 -	4.50
Resorcin, pure.....lb.	6.25 -	6.75
Salicylic acid, tech., in bbls. (110 lb).....lb.	50 -	52
Salicylic acid, U. S. P.....lb.	50 -	60
Salol.....lb.	90 -	1.00
Solvent naphtha, water-white, in drums, 100 gal. gal.	33 1/2 -	35 1/2
Solvent naphtha, crude, heavy, in drums, 100 gal. gal.	23 -	26
Sulphanilic acid, crude.....lb.	32 -	35
Toluidine.....lb.	1.70 -	2.50
Toluidine, mixed.....lb.	45 -	55
Toluol, in tank cars.....gal.	35 -
Toluol, in drums.....gal.	38 1/2 -	40 1/2
Xylidine, drums, 100 gal.....lb.	50 -	65
Xylol, pure, in drums.....gal.	47 1/2 -	50 1/2
Xylol, pure, in tank cars.....gal.	45 -
Xylol, commercial, in drums, 100 gal. gal.	32 1/2 -	35 1/2
Xylol, commercial, in tank cars.....gal.	30 -

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....lb.	\$0.36 -	\$0.39
Beeswax, refined, light.....lb.	37 -	38
Beeswax, white pure.....lb.	63 -	68
Carnauba, No. 1 (nominal).....lb.	90 -	95
Carnauba, No. 2, regular (nominal).....lb.	85 -	86
Carnauba, No. 3, North Country.....lb.	35 -	36
Japan.....lb.	17 -	18
Montan, crude.....lb.	25 -	26
Paraffine waxes, crude match wax (white) 105-110 m.p.....lb.	09 -	09 1/2
Paraffine waxes, crude, scale 124-126 m.p.....lb.	09 1/2 -	10
Paraffine waxes, refined, 118-120 m.p.....lb.	11 -	11 1/2
Paraffine waxes, refined, 125 m.p.....lb.	12 1/2 -
Paraffine waxes, refined, 128-130 m.p.....lb.	13 -	15
Paraffine waxes, refined, 133-135 m.p.....lb.	16 -	17
Paraffine waxes, refined, 135-137 m.p.....lb.	17 1/2 -	18 1/2
Stearic acid, single pressed.....lb.	20 -	21
Stearic acid, double pressed.....lb.	22 -	23
Stearic acid, triple pressed.....lb.	24 -	25

NOTE--Paraffine waxes very scarce.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls. gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....gal.	\$2.15
Pine oil, pure, deat. dist.....gal.	1.80
Pine tar oil, ref., sp. gr. 1.025-1.035.....gal.	48
Pine tar oil, crude, sp. gr. 1.025-1.035 (tank cars) f.o.b. Jacksonville, Fla. gal.	35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....gal.	87
Pine tar, ref., thin, sp. gr. 1.080-1.060.....gal.	36
Turpentine, crude, sp. gr. 0.900-0.970.....gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....gal.	35
Pine wood creosote, ref.....gal.	52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.....280 lb.	\$14.00	\$16.25
Rosin E-I.....280 lb.	16.60	16.75
Rosin K-N.....280 lb.	17.00	17.20
Rosin W (G-W).....280 lb.	17.25	17.50
Wood rosin, bbl.....280 lb.	15.00
Spirits of turpentine.....gal.	1.60
Wood turpentine, steam dist.....gal.
Wood turpentine, deat. dist.....gal.
Pine tar pitch, bbl.....200 lb.	8.50
Tar, kiln burned, bbl. (500 lb).....bbl.	14.50	15.00
Retort tar, bbl.....500 lb.	15.00	15.50
Rosin oil, first run.....gal.	72
Rosin oil, second run.....gal.	75
Rosin oil, third run.....gal.	92

Solvents

73-76 deg., steel bbls. (85 lb).....gal.	\$0.40
70-72 deg., steel bbls. (85 lb).....gal.	38
68-70 deg., steel bbls. (85 lb).....gal.	37
V. M. and P. naphtha, steel bbls. (85 lb).....gal.	29

Crude Rubber

Para-Upriver fine.....lb.	\$0.32 1/2 -	\$0.34
Upriver coarse.....lb.	20 1/2 -	22
Upriver caucho ball.....lb.	21 -	21 1/2
Plantation--First latex crepe.....lb.	33 -
Ribbed smoked sheets.....lb.	29 1/2 -
Brown crepe, thin, clean.....lb.	27 -
Amber crepe No. 1.....lb.	29 -

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.....lb.	\$0.16 1/2 -	\$0.18
Castor oil, AA, in bbls.....lb.	19 -
China wood oil, in bbls.....lb.	17 1/2 -	18
Cocoonut oil, Ceylon grade, in bbls.....lb.	15 -	16
Cocoonut oil, Cochinchina grade, in bbls (nominal).....lb.	16 1/2 -	16 1/2
Corn oil, crude, in bbls.....lb.	14 1/2 -	15 1/2

Louisiana

NEW ORLEANS—The Union Paper Products Co., 109 Tchoupitoulas St., has awarded the contract for the construction of a 1-story factory to Jos. Fromberg, 302 Little Guarantee Bldg. Estimated cost, \$112,748.

Maryland

BALTIMORE—The Bd. of Awards, c/o City Register, will soon award the contract for the construction of a sludge digestion tank, pipe lines, etc., at the sewage disposal works on the shore of the Back River here. A. E. Christhof, Highways Engr.

Massachusetts

CAMBRIDGE—The Suffolk Engraving & Electrotyping Co., 394 Atlantic Ave., Boston, has awarded the contract for the construction of a 6-story, 100 x 100-ft. manufacturing building on Main St. to the Simpson Bros. Corp., 166 Devonshire St., Boston. Estimated cost, \$225,000.

GREENFIELD—The School Bd. will soon receive bids for the construction of a 3-story high school at Federal and Sanderson Sts. A chemical laboratory will be installed in same. Estimated cost, \$400,000. Patton & Blair, 579 5th Ave., New York City, archts.

Missouri

ST. LOUIS—The G. J. Fritz Fdry. & Machine Co., 20185 3d St., has awarded the contract for the construction of a 1-story foundry addition to the Stupp Bros. Bridge & Iron Co., Frisco Bldg. Estimated cost, \$40,000.

New Jersey

NEWARK—The Amer. Can Co., 120 Fway, New York City, is having plans prepared for the construction of a factory. Estimated cost, about \$500,000.

North Dakota

MARMARTH—The Bd. Educ. will receive bids until Sept. 7 for the construction of a 2-story, 61x91-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000.

Pennsylvania

ALLENTOWN—The Allen Tire & Rubber Co., 510 Hamilton St., has awarded the contract for the construction of a 2-story rubber factory to the Allentown Constr. Co., 5th and Hamilton Sts. Estimated cost, \$2,500,000.

CHESTER—Allison & Co., Law Bldg., has awarded the contract for the construction of a 1-story, 30x85-ft. paint shop and dipping tank to the John R. Wiggins Co., Inc., Otis Bldg., Philadelphia.

COALDALE—The Bd. Educ. plans to build a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$150,000. John T. Simpson, Essex Bldg., Newark, N. J., archt.

NEW CASTLE—The Johnson Bronze Co., South Mill St., has awarded the contract for the construction of a foundry, etc., to the Moore-Lamb Co., Starrbaugh Bldg., Youngstown. Estimated cost, \$125,000. Noted Aug. 11.

Rhode Island

PROVIDENCE—Brown University is having plans prepared for the construction of a 3-story, 50x200-ft. chemical laboratory. Chemical equipment will be installed in same. Day & Klauder, 925 Chestnut St., Philadelphia, Pa., archts. and engr.

Texas

EL PASO—The Atlas Brick Co., Dallas and Cotton Sts., plans to construct a lime hydrating plant, etc. Estimated cost, \$60,000. Clarence L. North, pres.

PIHARR—The city received bid for the construction of a sewage disposal plant including a septic tank from R. O. Langworthy, \$20,000.

SAN ANTONIO—H. D. Kellar, Coldwater, Mich., plans to build a cannery and sirup mill here to include an ice factory, etc., for the manufacture of cane sirup, citrus preserves and marmalades.

Virginia

EAST RICHMOND (Richmond P. O.)—The Jefferson Tire & Rubber Co., Central Bank Bldg., is having plans prepared for

the construction of a 3-story, 80x240-ft. factory. Estimated cost, \$150,000. Akron Eng. Co., Akron, O., archt. and engr.

West Virginia

SCHINISTON—The Paquet Glass Co. is building an 80x120-ft. illuminating glassware factory. Estimated cost, \$25,000. P. J. Paquet, pros.

Wisconsin

CAMPBELLSPORT—The White House Milk Products Co., West Bend, had plans prepared for the construction of a 2-story, 50 x 110-ft. condensed milk plant. Estimated cost, \$75,000. M. Tullgren & Sons, 425 East Water St., Milwaukee, archts. Noted Aug. 11.

DURAND—The Bd. Educ. plans to build a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. H. Miles, secy.

Quebec

QUEBEC—The Standard Pulp & Paper Co., Ltd., will soon receive bids for the construction of a pulp and paper plant. Estimated cost, \$1,250,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Illinois.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1920 convention and exhibit at Columbus, Ohio, the week of Oct. 4.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, on Lake Superior.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PEAT SOCIETY will hold its annual meeting at Madison, Wis., Sept. 2, 3 and 4, 1920.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS 1920 annual meeting will be held in the Engineers Societies Building, from Dec. 7 to 10 inclusive.

AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS will hold its 14th annual convention at the Hotel Pennsylvania, New York City, Sept. 20 to 24, 1920.

ELECTRIC FURNACE ASSOCIATION will hold a meeting Oct. 6, at Columbus, Ohio, the subject of which will be "Refractories."

ENGINEERING COUNCIL will hold its next meeting in Chicago Thursday, Oct. 21, 1920.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SIXTH) will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12, 1920.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Chemistry to Be Represented On Super-Power Survey

THE acceptance by ARTHUR D. LITTLE of an appointment as member of the advisory board on super-power investigations of the United States Geological Survey will be noted with pleasure by all chemists. CHEMICAL & METALLURGICAL ENGINEERING has urged that the problems of chemistry be carefully considered in connection with these investigations, and it is a great pleasure, therefore, to note this striking assurance that the ideas for which we have stood are agreed to by the Government departments in charge of the work.

The coking of coal and development of byproducts therefrom promises to be one of our greatest chemical industries. Byproduct gas affords a means for transportation of energy from the mine field to the districts where fuel and power are required that does not in any sense interfere with simultaneous transportation of solid fuel by railway and electric current over high-tension power lines. The technology of such gas transfer is well known. It remains to determine the circumstances under which this medium of energy movement is most advantageous.

If gas is used as a medium of energy transfer, the production of byproducts of great value is assured. The chemist is vitally concerned, and chemical industry will watch these investigations with the utmost interest. To be assured that a prominent chemical engineer will be continuously available to advise regarding these problems is most satisfying.

The chemical industries must also be considered by the super-power investigators as important consumers of electric energy. Electrochemical developments afford an excellent supplement for other industrial power requirements, because the load can be so distributed as to make more uniform demand, filling up the hollows and reducing the relative heights of the peaks in the load curve. Chemical engineering attention is, of course, vital for the most advantageous use of this possibility.

Chemistry In the Kitchen

THE chemistry of cooking, so far as its practical application is concerned, is easy. The co-ordination of fats, proteins and carbohydrates into a balanced ration may be learned in a short course in domestic economy, and thousands of young aspirants to the dignity of the distaff in households of the future are studying it in fresh-water and salt-water colleges. How much of it they are learning is open to question. They may take the subject as a thing apart and apply their chemistry to "nutrition," but forget all about it when they think of a feast. The art of cooking is, indeed, much more subtle than the chemistry of ra-

tioning, and while the two are seldom wedded they are, indeed, parts of the whole and should never be separated.

With all the immense sums that we pay for eating we are not very intelligent in the preparation of our food. In an essay lately published in *Harper's Magazine* it was suggested that if a committee of intelligent persons from another planet were to visit the earth for the purpose of reporting on social conditions obtaining among its inhabitants they might well declare to their celestial authorities that, so far as we Americans are concerned, we miss more than is reasonable in the selection and preparation of what we eat. The imaginary high commission noted that, generally speaking, men and women differed in their attitudes toward food, in that men care more for its taste and odor than for its appearance, while women care more for its appearance than for its taste and odor. Nevertheless the preparation of food is assigned chiefly to women. Few women like to cook, and wherever it is possible they employ other women to do the work for them; and these other women have learned what little they know as a trade and not as a science or an art. The kitchen, they observed, is usually placed in the least desirable part of the house, and combined with it in the same room is the scullery, so that all the gross work of cleansing, peeling and cutting up is made part of the cooking, whereby the least agreeable and the most honorable duties of the household are combined in one. Distinction and honor accrue to the art of the cook because what he or she prepares becomes part of our very selves.

One of the reasons why living is so expensive is because competent persons have addressed themselves rather to discrimination in the selection of things prepared than to the selection of things to eat and the subsequent preparation of them. There is so little imagination and invention among cooks that they can make savory dishes only out of certain cuts of meat, while other cuts which cost much less could be made to taste better than the conventional expensive viands with the aid of a little intelligence and imagination. When we consider what the Chinese have done with the soy bean we should hang our heads in shame over our own stupidity with vegetables.

We know a man of science engaged in research whose salary was not increased in accord with the increase in living costs, and the problem of maintaining himself, his wife and four children became a serious one. Fortunately his wife had a scientific turn of mind and had been through a course of "domestic science," so together they began to balance their rations from a chemical standpoint. They prepared the amount actually needed, and found that it was less than had been their custom, and at first they felt themselves on short rations. A few weeks' experience taught them, however,

that they were eating all they needed, and this soon became all they wanted, while the family health improved.

Then came the development of the art as such, the use of herbs, many of which were unfamiliar, a happy diversity of flavors, and a much broader field from which to keep up a constant change in things eaten than before. The result is a complete rationing of the family at no greater expense than before the rise in prices, and with it the greater satisfaction of every member. The man and wife are, it is true, persons of rare and even unusual intelligence, and the results are what we may expect from the application of brains and intelligence to any problem. By thought and experiment they live better today at no greater expense for food than five years ago.

We believe it would pay the proprietors of large hotels and restaurants to retain the services of chemists of the first rank; men of imagination and culture as well as of laboratory technology, to engage in research in the preparation of foods. There are bakery and flour-testing and butter fat laboratories by the score, but these are not what we mean. We have in mind research and development in cooking, which includes baking and frying and broiling and steaming and roasting, with the use of imagination rather than the kitchen conventions in the selection and treatment of raw materials.

Soy Beans and The Chinese Character

IN THE *National Medical Journal* of China W. A. ADOLPH and P. C. KIANG tell at length of the nutritive value of the soy-bean products, and give information as to their preparation. The leading foods seem to be soy-bean milk, cheese, oil, and sauce. The cheese or bean curd has been the chief source of Chinese protein diet for centuries, and we can commend from experience the excellence of a good chop suey made with it. It is white, has about the consistency of calf's brain, and a delicate agreeable taste. Four methods of making it are given, and when the process involves the coagulation of bean milk with salt bittern, a curd is produced which is rich in all the inorganic essentials that are lacking in the bean proper. The authors suggest that some of the racial characteristics of the Chinese people may be traced to their dependence to so great an extent on this vegetable protein.

If they are right, and if the habits of industry and the disposition to mind his own business that distinguish the Chinaman are due to his diet of soy-bean cheese, let's have more of it in this country. Let's make it by the thousand tons and feed it to the millions.

If our present indisposition to work and our tendency to quit and then blame somebody else for our laziness is due to too much beef and pork and mutton let's give the bean-eaters a chance. Economics is not the main thing in life, and economics alone does not make or mar nations. Dietetics plays an important role. Better far a thousand years of beans than a century or so of too much meat if it is to be followed by collapse. The Chinese dallied with this ubiquitous and excellent vegetable as far back as B.C. 2838. They should have some experience with it by this time, and we have yet to learn of an anti-bean bill in the legislative halls of that country.

Resistance Between The Cup and the Lip

IN OUR issue of July 28 we published a paper by Dr. ALVIN J. COX on Philippine industrial material, products and resources available to the United States. It was an illuminating catalog of supplies. It showed that the islands offer immense quantities of the following materials, subject, of course, to proper development: Manila hemp, sisal and maguey, tobacco, sugar from cane and palm coconuts, including copra and coconut oil; alcohol from molasses, nipa palm (from which 5,000,000 gallons or 10,000,000 proof gallons are made annually) and from cassava, arrowroot, yams and sugar palm; buri palm fiber for buntal hats which we call "Bangkok" and are so light that whoever can afford to wear them in summer at present high prices will wear no other if his wife will let him; rattans, coir fiber for brushes, ropes and doormats; tree cotton or kapok, which is an oily, short fiber, susceptible to many uses; resins, terpenes, perfumes, edible nuts, and a large variety of vegetable oils; coffee, cacao, papaya gum, strychnine, the leaves and seed of *Datura alba*, which, on extraction, produce a valuable remedy for asthma; rubber, lumber and tanning materials, paper pulp from bamboo (especially *Canabojo*), abaca or Manila hemp waste, rice straw and other paper stock; honey, silk, and a large variety of products of the sea. In minerals there are silver, gold, copper and well-located deposits of iron, the ore being workable, high in iron content and well located. And there is manganese in abundance. The petroleum outlook is very favorable. Coal is imported but is present in large quantities, unmined. Cement material and limestone are plentiful; so are asbestoform materials and so is bat guano. There are resources in fireclay, abrasives and sulphur. There is great need for island-made caustic soda, bleaching powder, lime, sand-lime brick, salt, chloroform and glass, to mention but a part of the list.

'Tis a grand bill of fare, if we, who published it, do say it. If this country were industrially organized the speedy development of many industries would follow. This would add to the sorely needed stores of manufactured materials both here and abroad and bring down the cost of living and of things required in the practice and arts of civilization.

American capital is ready to go abroad and afield, American management in industrial affairs has proved itself as competent as British or German management; in some countries it bears a superior reputation. The trouble seems to lie between knowing that the stuff is there and knowing just how to go about to get it. We need, however, to qualify the statement that American capital is ready to go abroad. It is shy about taking the first step and that is—to pay for *all* the information needed. By far too often it has rushed in—and we lay no stress on Philippine development in this respect—without adequate knowledge. In the islands referred to, for instance, there are great holdings in possession of religious orders, and while these associations are not averse to profits it is necessary to negotiate with them and to understand their points of view and habits of mind. More important still is the industrial survey which, in the making, must be backed by scientific proficiency and acumen, engineering competence in the calculation of costs, as well as in the ability to design and construct, together with keen business common sense and honesty.

Occasionally a technical man is sent out to give a proposal the "once over" and the chances are that he will miss the key to the situation, and then whichever way he decides is likely to be wrong. What is needed is a promotion organization that is in no hurry to make money; the profits of which, beyond costs for services rendered, are to come from industries after they have been established. And such an institution must have modest ideas of bankers' commissions. It requires also better administrative ability than is easy to find, because the diversity of requirements is coupled with the diversity of opportunity.

We believe the best method for such development would be for a kind of organization to be formed between some high-class promotion corporation (and there are a few such) together with selected representatives of such industries as cordage, tobacco, sugar, oil, industrial alcohol, straw hat, furniture, drug, rubber and others, and always including transportation. Competitors are still shy of joint conferences, or of letting one another know what they are doing; and since they will not change their natures it would be better to take them separately. The main thing to pay for would be information, for complete industrial surveys which should be made by the most competent men available. Then the promoting company could co-ordinate the information, and provide for the mutual aids and conveniences to be enjoyed by the various pioneers. The sugar man and the straw hat manufacturer may not have much in common, and yet they might find themselves indicated as neighbors by the survey.

In short, we should like to see organized research applied to the international and overseas business of the United States.

It would be a great help.

The Right Chain

And the Right Sprocket

USUALLY when a link gives way in a chain drive the plant mechanic hooks in a new one and turns on the power again. If any attempt is made to account for the accident, nine times out of ten it is laid to overloading the conveyor, pump, mixing machine, etc., and to avoid a recurrence the charge to the machine is materially cut down to suit the power delivered by the drive. The lack of good design seldom comes into consideration, probably because very little is known about the subject. General rules are applied, usually, such as: For durability a short pitch is better than a long one; the sprocket centers should not be closer than forty times the pitch of the chain; the under side of the chain should be the slack one; large sprockets and a large number of teeth give less wear; the ratio of sprockets should not be less than 5 to 1 and sixteen teeth should be the minimum used; adjustable shafts should be used to take up wear. But no concrete conception of the phenomena involved is presented.

In printing a Study of Chain Driving in this issue we are making Mr. LAWSON's article in *Engineering* available to our readers, many of whom have more than a remote interest in this branch of machine elements. Attention is directed especially to the subject of impact and the effect of an oil film on chain elasticity. The formula on the life of chain is ideal engineering computation. It involves the selection of the right chain and the right sprocket.

Pig-Iron Statistics Are Informing

STATISTICS usually are considered rather "dry," but the statistics of pig-iron production are quite illuminating as to the proportions of the iron and steel industry. The American Iron and Steel Institute has just issued its midsummer pig-iron statistics, showing the production in the first half of this year. The total shown for the output, 18,435,602 gross tons, is one of the least interesting things in the presentation. The trade knew in advance approximately what output would be reported.

As a matter of record, however, it may be mentioned that the maximum half year's output was the 20,826,914 tons made in the second half of 1918, while in the past three half-years output has been as follows: First half 1919, 16,278,175 tons; second half, 14,737,189 tons; first half 1920, 18,435,602 tons. With reference to capacity, under reasonably favorable working conditions, such as obtained in 1916 except for the last two months of that year, the furnaces can probably turn out about 46,000,000 tons of pig iron in a year, so that production in the first half of this year was at 80 per cent of commercial—not rated or theoretical—capacity. That was a good showing considering the great difficulties encountered, particularly in the matter of transportation.

The statistics show that coke is practically the universal fuel in making pig iron. A little bituminous coal is used raw, less than 0.25 per cent of the coke used. A still smaller quantity of anthracite is used, less than 1 per cent of the pig iron having been made with use of any anthracite, and even with that pig iron coke was used largely in mixture with the anthracite. In 1890 2,186,411 tons of pig iron was made with anthracite.

In the first half of this year 155,612 tons of pig iron, was made with charcoal as fuel, that being 0.8 per cent of the pig iron output.

Of the pig iron made in the first half of this year 46 per cent was basic iron, while 32 per cent was bessemer and low-phosphorus iron, making 78 per cent for the two "steel-making irons." The comparison is accurate enough, but it is not exact, because on the one hand some of the bessemer iron was produced primarily for making ingot molds, the subsequent use of the worn-out molds in making steel being incidental, while on the other hand in the 22 per cent of "all other" are included spiegeleisen and ferromanganese, which are employed chiefly in steel making. In the year 1907 the production of bessemer iron was more than double the production of basic iron, while in the year 1913 basic iron took first place.

Marketwise, however, the grades of pig iron stand in altogether different relations. Of the total pig iron made, 29 per cent was made for sale, the other 71 per cent being made by consumers. Of the iron made for sale only 20 per cent was basic iron, while only 10 per cent was bessemer and low-phosphorus. Foundry and ferrosilicon comprised 54 per cent while malleable contributed 12 per cent more. No small part of the bessemer, low-phosphorus and basic iron sold was for making steel castings. It may be estimated that of all the "merchant pig iron" made about 80 per cent goes into steel, gray iron and malleable iron castings, including ingot molds, whereas of all the pig iron produced fully 75 per cent is used for making rolled steel.

British Chemical Industry

FROM OUR LONDON CORRESPONDENT

London, August 9, 1920.

BUSINESS at the moment is somewhat stagnant, partly owing to the holidays and mainly, perhaps, on account of the serious international situation. Prices of imported chemicals are somewhat higher, but the home chemical trade is dull, with values falling slightly. It is thought, however, that the next month will show a very considerable improvement, especially on export account.

CHEMICAL COMPANIES' RESULTS

Recent reports of progress in chemical undertakings are of a disappointing nature. Thus the dividend on the preference shares of the British Cellulose & Chemical Manufacturing Co. has been postponed, the reasons given being delay in obtaining machinery and plant and the after effects of strikes, etc. It will be remembered that this company is to manufacture artificial silk and "celluloid" products made from acetyl cellulose, and while it is stated that production on a large scale is to commence shortly, the general impression seems to be that the plant has been inefficiently and too lavishly planned and that considerable reorganization will be necessary before remunerative results are obtained. The Alby United Carbide Factories has also failed to declare a dividend owing to shortage of raw materials such as coal and on account of serious losses caused by strikes. The history of the company is a very interesting one and it appears to have been universally successful until it took an interest in the Nitrogen Products Co. with its attendant share manipulations.

An interesting feature of the report is the statement that it is now possible to manufacture carbide on a commercial scale from inferior carbon material using an "agglomerate" patented by the company. Ultimately a committee of inspection was appointed by the shareholders to assist the Board and to watch the shareholders' interests. Brunner Mond & Co. have allocated \$400,000 in furtherance of scientific and industrial research, the resolution giving effect to this proposal of the directors having now been carried after it had previously been rejected by the shareholders at the recent annual meeting.

DEVELOPMENTS IN NITROGEN FIXATION AND RUBBER VULCANIZATION

Preliminary details of the Claude process previously referred to have now been published in the *Chemical Age*, London, of July 17, and results of large-scale working will probably be forthcoming before the end of the year. Meanwhile it is understood that the nitrogen fixation process via barium cyanide of the British Cyanides Co. has proved commercially successful and an announcement in this connection is to be made shortly. The chief difficulty seems to have been the question of temperature and suitable refractories for the furnace lining. Similarly, Dr. Calvert's process, which is being developed by the Cyanides Trust, Ltd., was rendered possible only by the use of a new resistant nickel-chromium alloy, "Cronite," and it is understood that while not yet on a commercial scale, manufacture on a large laboratory scale is proceeding with very satisfactory results. An interesting patent is that of

Peachey, No. 146,734, for the cold vulcanization of rubber, the process having been developed at the Manchester College of Technology. A company with a capital of \$1,000,000 has recently been formed to develop the process, which is somewhat revolutionary in character.

SOCIETY OF CHEMICAL INDUSTRY'S ANNUAL MEETING

In spite of the presumed considerable influx of American visitors to this country at the present time, Americans and Canadians were conspicuous by their absence at this meeting, probably because Newcastle is a relatively long way from London. The conference on filtration promoted by the Chemical Engineering Group disclosed the fact that there is shortly to be an amalgamation of the various interests developing centrifugal filters such as that of Gee and Sturgeon, while the company developing the Sharples centrifuge will probably also be included. The difficulties of continuous operation and of washing the precipitates can be best overcome by such amalgamation and as regards washing, it is probable that the principle of "steeping"—i.e., filling the machine with water to soak into the precipitate—will be adopted. Other interesting features of the meeting were discussions on the increased rate of subscription, the general question of increased publicity and the advisability of forming a British Institute of Chemical Engineers. As regards subscriptions, the point was raised that the interests of American and Colonial members, as well as those of the Society, would be best served by preferential treatment as against British members, while the formation of a British Institute of Chemical Engineers was considered informally, not with a view to separation from the Society of Chemical Industry but to enable chemical engineers to have a voice in the proposed general registration of practicing engineers in this country and to provide facilities for qualifying chemical engineers as and when education in this important subject has been adequately developed. The cinematograph was used for the first time in illustrating one of the papers read before the Chemical Engineering Group, Mr. Kestner, the recipient of the Society's gold medal, being in the chair.

PERSONAL NOTES

Lord Moulton was presented at a dinner held on July 21 with a Georgian loving cup in recognition of his personal and national services, and while his services were really called upon at a time when he "was really too old for his job," there is no doubt that his magnetic personality was the source of inspiration to those who worked under his general direction and that it required a man of his character and achievements to bring about that degree of co-operation among chemical manufacturers which was so lamentably lacking before the war and which is now proving of inestimable benefit to the industry. Dr. T. M. Lowry, F.R.S., has been appointed professor of physical chemistry at Cambridge, G. O. Banister professor of metallurgy at Liverpool University and Dr. R. V. Wheeler to the new chair of fuel technology at the University of Sheffield. The latter's researches in the constitution of coal are classical, while Dr. Lowry's work at the Ministry of Munitions has received full recognition. Sir John Cadman, Director of Petroleum to the British Government, has been appointed a member of the Advisory Council for Scientific and Industrial Research.

Lake Superior Meeting of the A.I.M.E.

Report of the 122d Meeting of the American Institute of Mining and Metallurgical Engineers, Giving Short Descriptions of the Lake Superior Milling and Smelting Practice and of Some of the Papers Presented

LAKE Superior region was the scene of the 122d meeting of the American Institute of Mining and Metallurgical Engineers, their technical sessions starting at Houghton, in the "copper country," just twenty years from the date of their last visit. Over a hundred members of the party had been gathered together since the previous Friday morning on board one of the lake passenger steamers, en route from Buffalo. On this journey the usual pleasures of a water voyage were experienced, ranging from "rubber-neck" wagons at the ports of call to a strong north wind on Lake Huron, either of which was well calculated to disturb the equanimity of the dignified.

That storm so delayed the boat's arrival at Houghton that no inspection trips were possible Monday afternoon, except for those members who had foregathered by rail. Tuesday, however, the Engineers grouped themselves in small parties and were motored over any route which their interests suggested, examining geologic formations, mining methods, surface plants, mill, smelter, refinery or reclamation plant as they desired. Luncheon brought them together at a little bay on the extreme northern end of Keweenaw peninsula, where a picnic full of local color was enjoyed by visitors and hosts. The visitors dissected the anatomy of a "pasty," and enjoyed a four-cornered wrestling bout done in true "Cousin-Jack" manner, while the hosts were able to get impressions of Mr. Hoover from many angles.

VISITORS PROVIDED WITH EVERY COMFORT

Mining men who have acquired tender feet from prolonged use of subways and golfing togs certainly have nothing to complain of the many thoughtful attentions given by those in charge of their entertainment in Houghton. Visitors were housed in a rolling hotel composed of Pullman and dining cars, complete enough in itself, but given the finishing touch by the early morning arrival of a road engine, which furnished steam heat and hot water, a comfort well appreciated by anyone who can remember the morning chill in northern woods.

SIGHTSEEING AND SOCIAL EVENTS TAKE PRECEDENCE

Sightseeing and social events took more marked precedence at this 122d meeting than for many past occasions. Relatively few technical papers describing details of local mining and metallurgical operations were read, this deficiency being atoned for by the presentation of a 260-page "Handbook of Mining in the Lake Superior Region," prepared by Alexander N. Winchell, professor of mineralogy, University of Wisconsin, and by the engineers clubs of northern Minnesota and Duluth. Personal inspection also shows improvements in many important operating details, many of which are well worth attention in technical literature. Possibly in no other region could a visitor see Collom tappet jigs and low-pressure steam turbines operating in the same mill, nor a blast furnace making block copper close neighbor to an ammonia leaching plant.

LAKE SUPERIOR MILLING AND SMELTING PRACTICE

Lake Superior milling and smelting practice is distinctly an adaptation to local needs. Primary crushing is done in steam stamps because that is the only high-tonnage machine which will not be "frozen" by the occasional piece of mass copper which slips through. After stamping through $\frac{3}{4}$ in. the ordinary practice, as illustrated by the Quincy mill, was to get a little copper by launder jigs before the $\frac{1}{2}$ or $\frac{3}{8}$ in. material (oversize crushed by rolls) was jigged in Collom tappet jigs. The hutch product of these was classified and fed to more jigs, the middlings of which joined the classifier overflows, were settled and cleaned on tables. Such practice—what with the peculiar association of gangue and native copper—gave a recovery of approximately 15 lb. of copper and a tailing of 7.5.

Recent improvements made by Ralph Hayden at this mill have cut the tailing in half, with a corresponding recovery. He substituted real jigs of ample capacity for the "oversize" launder jigs, and sized the roll product so that three separate banks of machines are handling material of certain limiting dimensions. This was in an effort to catch as much mineral in the coarse form as possible, and relieve the machines handling finer products of just that much duty. All jig tailings are then reground in ball mills and passed over a system of primary, middling and cleaning tables.

Older practice at the Calumet & Hecla mill has produced a tremendous volume of much higher-grade tailings than the various amygdaloid ores produce. This is now being reclaimed, reground and settled and the values in the sands leached by ammonia solution,¹ while the slimes are cleaned in flotation machines. This new plant is a model in many ways, and thoroughly in keeping with modern engineering advance.

It contrasts sharply with the primitive 10-ton melting and refining furnaces used to profusion in the smelters. Not that this plant is devoid of improvements, for it has one battery of three large furnaces equipped with every improvement: charging machine, casting machine, pulverized fuel and waste heat boilers. Necessity for keeping various ore receipts separate and the impracticability of accurate sampling have prevented the more widespread installation of modern labor-saving devices. Studies and complete plans have lately been made by the C. & H. staff, working in conjunction with C. H. Repath, involving radical changes in this layout, an improvement which is now held up by unfavorable market conditions. A feature of the new plant will be the separation of the melting from the refining stages—now done successively in the same furnace.

Large reverberatories similar to those in use in Western plants will melt the mineral, delivering practically pure molten copper to the refining furnaces, there to receive the finishing touches.

¹Process devised by C. H. Benedict (see *Eng. & Min. J.*, July 14, 1917, p. 48), similar to that described in *CHEM. & MET. ENG.*, Vol. 20, No. 7, April 1, 1919, p. 328.

On Tuesday, Aug. 24, the party went to Marquette, Mich., and inspected the plant of the Cleveland-Cliffs Iron Co.

The original Pioneer charcoal furnace, the first in Michigan, was built in the City of Negaunee in 1857, and was operated almost continuously until 1895, when it was abandoned. In February, 1890, the Pioneer Iron Co. was acquired by the present owner, the Cleveland-Cliffs, Iron Co. This was the beginning of the furnace and chemical department of this company. In 1903 the Pioneer furnace at Marquette was completed and went into blast in connection with the chemical and byproduct plant, and has operated continuously since that time. It is 70 x 13 ft. with a 7 ft. hearth. To supply this furnace with charcoal under normal running conditions, eight acres of hardwood is cut over daily, making about 200 cords of wood. Its capacity is 130 tons of pig iron per day.

In addition to the basic products (methanol, methyl acetone, acetate of lime), the chemical plant produces c.p. acetone, acetic acid, formaldehyde, flotation oils, insulating pitch, sodium acetate, sulphuric acid, iron liquor, methyl acetate, special solvents, hexamethylenamine and pure creosote.

The methanol and acetone are used principally for solvent purposes and in the production of dyes; acetic acid for the cutting of lead, production of vinegar and dyes; formaldehyde as a disinfectant, preservative, treatment of seeds to prevent smut, scale, etc., and in the production of insulating material, such as bakelite, etc. Hexamethylenamine is chiefly used as a drug, largely in cases where internal disinfection is required.

The wood is prepared mechanically, coming in as logs and going through the splitting and block mills, coming out in 8-in. lengths, where it is put into pre-driers, which are heated by the waste gases from the retorts. By this means charcoal can be put in the blast furnace within seven days from the time the tree is cut.

The furnace and also the chemical plant are thoroughly modern. The furnace is equipped with self-dumping device for the charcoal, has steel ore bins, motor-driven scale cars, skip hoist and revolving top.

Technical Papers Presented

SURFACE CHANGES OF CARBON STEELS HEATED IN VACUO

E. HEATON HEMINGWAY and GEORGE R. ENSMINGER described some experiments made at the Watertown Arsenal on "Surface Changes of Carbon Steels Heated in Vacuo." After heating a highly polished piece of 1.01 per cent carbon steel at 1,000 deg. C. for six hours there appeared on the cooled surface, when examined at 500 magnifications, very delicate pearlitic grains outlined by ragged continuous markings, lightly depressed, the whole probably representing the structure stable below the transformation. Clearly independent of these figurings, deeply marked polygonal crystal outlines, with straight elements, represented the gamma boundaries. A third system, suggestive of broad shallow valleys, more or less independent of either, was thought to represent the boundaries of former gamma crystals that have been absorbed by crystalline growth.

This outside layer of carbon-free iron was very thin—a moderately heavy polishing, followed by the usual etching, would exhibit the original hypereutectoid structure. Similar markings remained on lower carbon steels after a similar heating, but in this case the depth of the

pure iron was considerably deeper, although not so deep as found by Rawdon and Scott.¹

Study of the deposits formed on the inside of the vacuum tube led the present authors to the conclusion that the outside layer containing the characteristic markings consists of a ferrite volatilized at the high temperature and redeposited below the temperature at which solid solution exists. Any iron oxide existing on or in the steel would also tend to cause decarburization by breaking down cementite with formation of corresponding amounts of carbon oxides.

UTILIZATION OF TITANIFEROUS IRON ORE

An interesting paper on "Utilization of Titaniferous Iron Ore," as practiced in New Zealand, was presented by J. A. HESKETT. Large quantities of titanium-bearing iron beach sands are available; these, however, contain large quantities of ferrous oxide. Accepting the established opinion that such an ore would smelt slowly, the author made a mixture of equal parts of the sand and coking coal, coked the combination, producing a ferrocoke having 36 per cent metallic iron and 40 per cent carbon. This was then charged with limestone into a 3 ft. x 8 ft. cupola, and produced ten tons per day of very close-grained gray iron. However, the coke broke up into very fine particles and gradually plugged the furnace.

Briquetting and coking a 1 coke : 3 sand mixture, using sodium silicate for binder, and then smelting with coke and limestone gave no fines and a free-running slag, yet the iron was white. The briquet evidently contained sufficient carbon to deoxidize the ore, yet the time in the coking process (30 min.) was insufficient, resulting in direct reduction immediately above the tuyeres at comparatively low temperature.

Using a 45-ft. blast furnace (8 ft. bosh, 4 ft. hearth) with 20-oz. blast at 1,000 deg. F., the charge consisted of briquets containing 50 per cent iron. These were made by grinding eight parts sand and one part coal to an impalpable powder, pressing and carbonizing. Slags were very fluid, but coke consumption was high, and the hearth gradually built up with a mixture of coke, ferrotitanium and cinder. By tapping at short intervals (2 hr.) this high-titanium mixture was flushed out of the furnace between iron and slag. It appeared that approximately 85 per cent of the TiO₂ content in the ore was accounted for as a slag constituent. The remainder was divided, 5 per cent into a high TiO₂ cinder, and the rest in ferrotitanium.

Their experience is that their pig iron will not "grain out" as will other irons of similar analysis. It has a ready tendency to chill to a depth of less than $\frac{1}{8}$ in., even in sand castings, and despite the fact that the iron contains 2.5 per cent Si and 0.04 per cent S. This is usually accompanied, however, by an excellent surface appearance and a strength about 25 per cent higher than expected.

NITROGEN IN STEEL, AND THE EROSION OF GUNS

When studying the structure of failed steel bottles which had contained nitrogen and hydrogen at high temperatures and pressures (in the Haber process), H. E. WHEELER observed a decarbonized inner case, structureless under normal etching agents, and permeated by cracks. Its scleroscope hardness was 20, but a small amount of cold work increased it to 75. Under

¹CHEM. & MET. ENG., vol. 22, No. 7, April 28, 1920, p. 787.

the microscope no pearlite was evident, although chemical analysis showed from 0.05 to 0.58 carbon, depending upon the alloy steel under examination—chromium-vanadium steel being the most resistant. No satisfactory method for determining nitrogen in this metal was available at the Watertown Arsenal, where the investigation was conducted.

Normalizing at 1,000 deg. C. in vacuo closed the cracks, and caused the reappearance of considerable pearlite in the affected zone, the latter change not occurring if the sample was heated in the air, while the former change was due to relief of internal stresses.

Small cylinders of various analyses were then heated in ammonia for 20 hr. at 650 deg. C. and cooled in the same atmosphere. Nascent nitrogen from such treatment forms Fe_3N , this compound being stable below 450 deg. C. Carburization also occurs in low-carbon irons by pyridine or hydrocarbon impurities in the gas, while decarbonization takes place in hypereutectoid steels. Washed metal is apparently unaffected, while white cast iron becomes coated with solid iron nitride $\frac{1}{2}$ in. deep, a layer easily removed and analyzing Fe_3N plus about 1 per cent carbon. Many alloy steels were studied in this way, and it was concluded that the alloying elements did not combine with the nitrogen, but affected the penetration only as they affected the carbide. Nickel steel, for instance, heated above the critical for 12 hr. gave, when cross-cut, polished and etched, a deep white case, grading into martensite, and thence into a central zone showing pronounced dendritic structure, which latter is reverted to the normal pearlite grains by vacuum treatment. Cold work greatly assists the penetration, the work apparently shattering the cementite so that it is more easily taken and retained in solid solution by the combined action of heat and nitrogen.

These effects were so similar to the oft-described phenomena accompanying gun erosion that Mr. Wheeler proposes a new hypothesis for the cause of this deterioration. Briefly it is that the hard white layer on the inside of an eroded gun is a locally cold-worked (and therefore hard) austenitic case due to penetration of nitrogen at the high pressure and temperature during the course of an explosion.

CASTING AND MOLDING STEEL INGOTS

EMIL GATHMANN presented a brief paper on "Casting and Molding Steel Ingots," in which he classified steel into three divisions: *A*, non-effervescing, killed, or solution steel so made that the lower portion of the ingot is free from blowholes, segregation or pipe; *B*, effervescing gassy or evolution steel, making an ingot containing deep-seated blowholes without pipe or shrinkage cavity; and *D*, a midway class of less commercial importance and ease of definition. Division *A*, comprising only one-eighth the American production, is used for superior-quality material, ordnance, rails, and high-strength materials. *D* cannot be used where surface finish is important. *B* and *D* are usually squared on the ends only, total discard amounting to 20 per cent. Division *A* must be cast big end up to prevent concealed pipe by crystals bridging across the molten center; easy commercial methods for stripping such ingots have been devised, and approximately 1,000,000 tons is made in this manner each year. Killed steel should possess 0.20 residual silicon, while effervescing steel obviously must have silicon and other deoxidizers in very small quantity. When cast properly at low temperature into hot molds, piping steel can be made with only 5 per cent discard.

The molds must have large mass near the base, and be devised so that the top is kept molten to the last, preferably by auxiliary heating.

Type *D* steel cannot be improved by any known mold-design short of fluid compression. Best results in type *B* are had when ingots are bottom cast,* although superior results regarding deep-seated blowholes and freedom from "snakes" have been effected by so-called top-bottom casting, where a large volume of very hot steel enters the mold at low pressure and velocity. One large unsolved problem in this type of steel yet remains, however, which is the prevention, or rather reduction, of segregation.

NOTE ON PRO-EUTECTOID FERRITE

When studying the structure of a cast-steel runner (0.35 per cent C, 2.69 per cent Ni) CHARLES V. CLAYTON noted a peculiar occurrence in the pearlite kernels. Ordinary reticular structure was observed at low power, but on higher magnifications the very fine, almost sorbitic pearlite granules exhibited white ferrite markings arranged like Widmanstätten bands ordinarily, but often as swirls or rosettes.

The author supposes that a whirling motion in the liquid steel rounded the tips of dendritic branches, upon which low-carbon austenite would be precipitated, due to the selective freezing or differential crystallation noted by Foley,* which upon passing the transformation range would give birth to the bent ferrite plates.

Variation in Length of Wood Fibers

A new conception of wood fibers is given by the great number of measurements that the Forest Products Laboratory in Wisconsin has made. The length of the fibers, instead of being uniform and characteristic in each species, has been found to vary more in a single tree than in the average for different species. One Douglas fir had fibers ranging from 0.8 to 7.65 mm. in length, though several thousand measurements showed the average for the Douglas fir to be 4.41 mm. and for the long leaf pine 3.76 mm.—a difference in the average for the two species of less than 1 mm., or one-twenty-fifth of an inch. In early growth, up to twenty to fifty years, the fiber length increases strikingly from the center outward, but after the maximum has been reached the variation is small, even though the tree live to 400 years or more. There is also some increase in fiber length from the butt of the tree upward for about two-thirds of the distance to the top. Each annual ring shows variation, the wood of early spring having longer fibers than that formed last in summer.

Develop Bonding Clays

Blends of bonding clays for use in crucible manufacture, which have been in process of development at the Ceramics Station of the Bureau of Mines at Columbus, Ohio, have reached a point where the Bureau is confident that the entire sufficiency of domestic clays has been proved. Since bond clay must possess a variety of properties, such as plasticity, bonding strength, slight shrinkage and a tendency not to slag, no one clay has been found entirely adequate. Requirements for all uses are being met, however, by the blends which are being developed. A number of domestic clays have been developed which have been found to be superior to the clays imported before the war.

Conversion of Walnut Shells Into Poultry Charcoal in a Rotary Kiln

BY HARRY L. GLAZE and RAYMOND B. STRINGFIELD*

TO CONVERT walnut shells, a waste product, into poultry food, a salable commodity, seems at first glance a difficult problem, but in reality it is quite simple. The solution of the problem brought out several features capable of rather wide application.

Briefly, the problem was this: From the walnut crop of southern California there are produced many tons of nuts which are scarred or otherwise off grade. These were formerly discarded or sold for next to nothing. With the development of a cracking machine, the meats from the cull nuts were made to yield a profit, but there remained as a waste product a thousand tons or more of shells per year. These were expensive to handle and bulky to dispose of. Used as a fuel, they proved to be unsuitable when burned loose, and were difficult to briquet. The available tonnage was too small to permit of the profitable operation of a retort process for the production of charcoal, acetic acid and creosote. Several attempts made to develop a profitable outlet for the shells had proved unsuccessful.

Upon investigation it was found that many tons of willow charcoal were brought into southern California each year to supply the large poultry ranches; it was also found that walnut charcoal was even better than willow for this purpose. Experience with the incineration of kelp in a rotary kiln for the recovery of its potash content convinced the authors that charcoal could be produced economically in a similar type of apparatus, and operation of the completed installation proved this surmise to be correct.

DESCRIPTION OF PLANT

The feature of the installation is its extreme simplicity resulting in low power and labor costs. Incoming shells from the walnut cracking plant are fed into the hopper of a No. 2 Sprout-Waldron corn grinder, the hopper being set flush with the unloading platform. The grinder reduces the shell to approximately 4 mesh, with the production of very little dust and fines. The product weighs about 31 lb. per cu.ft. A bucket elevator delivers the ground shell to a storage bin of five tons capacity. The bin has a 45 deg. hopper bottom, closed by an adjustable vertical gate, through which a reciprocating slide feeds a regulated quantity of ground shells into the kiln at each revolution.

The kiln is a steel shell 20 in. in diameter and 19 ft. long, lagged on the outside with asbestos felt 1 in. in thickness. This is mounted on trunnions and has a slope of 1 ft. in 10. There is a special arrangement of lifters and baffles designed to secure agitation of the shells during charring. It has been found that proper agitation is especially important, as it was almost impossible without it to control the conditions of charring. A chain drive rotates the kiln at 10 r.p.m. The regulated discharge from the storage bin flows into a hopper from which it is fed into the kiln by a rotary scoop such as is commonly used on ball mills. Through an 8-in. hole in the center of the scoop pass three 1½-in. ordinary type gas burners. These have atmospheric mixers and ¾-in. openings and burn 3 cu.ft. of gas per minute each.

As the ground shells enter the kiln, they pass through the flame and into a zone of high temperature. Active decomposition begins immediately and is accompanied by the complete combustion of the dust formed in grinding. About 6 ft. from the inlet end of the kiln an exothermic reaction sets in, the burning ceases and energetic distillation takes place. This is accompanied by dense clouds of creosote-bearing smoke. In the last few feet, distillation is completed, and the thoroughly charred shells are cooled. The charcoal discharges into a hopper and is quenched by a water spray. From the hopper it is conveyed to a rotary screen yielding 4-, 6- and 10-mesh products, which are sacked. The product is of excellent quality, free from dust, and of slightly higher gas-absorbing power than ordinary willow charcoal. The yield is slightly over one ton of charcoal per three tons of shells.

The flue gases are blown by means of a 10-in. fan into a scrubber, where practically all of the tar and creosote is removed by means of sprays. About 40 lb. of tar is recovered per ton of shells. The tar is suitable for use as a timber preservative. On distillation it yields excellent grades of creosote, heavy oil and pitch. No attempt is made at present to recover the acetic acid and other soluble constituents of the spray water.

COST OF OPERATION

The plant has proved simple and economical to operate. The feed is easily regulated and the shells are thoroughly charred without ashing. The grinder can be so regulated that practically the entire product is between 4 and 10 mesh. A 10-hp. motor furnishes ample power, drawing only about 4 hp. average load. Four men operate the plant—one per shift, with an extra man on the day shift to sack charcoal and do repair work. The chief source of trouble is the flue connecting the kiln with the scrubber, which catches considerable tar and burns out occasionally, making it necessary to clean out the flue every few days.

The plant has a capacity of three tons of shells per 8-hr. shift, yielding slightly over three tons of finished charcoal per twenty-four hours. Neglecting overhead and the cost of shells, the present cost of operation is:

Capacity: *	
Twenty-four hr. operation, 18,000 lb. shells, 6,000 lb. charcoal	
Operation Cost per Day:	
Three men at \$5.....	\$15.00
One man at \$4.....	4.00
Gas at \$1 per ton of shells.....	9.00
Electricity at 6c. per kw.-hr. for 4 hp.....	4.56
Water	1.50
	\$34.06
Cost per Ton of Charcoal:	
Operation	\$11.35
Sacking at 26c. per sack.....	4.00
Cartage on 3 tons of shells.....	3.00
	\$18.35

Since poultry charcoal is selling on the Pacific Coast at \$50 per ton and up, it will be seen that the plant is a profitable venture, even neglecting the value of the tar and creosote recovered as a byproduct.

Test runs have been made on apricot, peach and prune pits and on ordinary sawdust and shavings, and excellent results have been obtained in each case; the charcoal, of course, varies with the raw material. As the initial cost of the equipment is low, this type of plant with its flexibility and small operating cost may solve the waste disposal problem of other industries, even of those operating only a few months in the year.

Los Angeles, Cal.

Chicago Meeting, American Ceramic Society

Abstracts From President Minton's Remarks on His Investigations of the Economic Situation of the Ceramics Industry and Business Conditions in Germany—Short Notes on the Visits to Some Chicago District Industrial Plants

THE summer meeting of the American Ceramic Society, in accordance with the usual custom, followed a program of inspections of manufacturing plants, no papers being presented. The opening feature was the banquet at the Hotel LaSalle on Monday night, Aug. 16.

W. D. Gates, the dean of Chicago ceramists, presided at this function. Secretary Binns and Mr. Gates, charter members of the society, indulged in reminiscences of former times to the delight of the guests.

The chief address was delivered by President Minton, who had just returned from an extended trip through Germany investigating the ceramic industries and business conditions. His remarks covering general conditions are given in brief below.

PRESIDENT MINTON'S ADDRESS

"My journey was by way of England and Holland to Berlin, thence to Essen, Cologne and the Rhine cities. I found conditions very bad, the food supply being inadequate with nothing but black bread and potatoes available in the smaller cities. At the large hotels in principal centers there is plenty of food at fabulous prices, which accounts for the optimistic reports of some travelers. Everything is issued on cards as during the war and 100 g. of bread per person is the daily allowance. Importation of other than gift food is not allowed by the authorities, who are desirous of conserving the supply of available cash. Some food is smuggled in through Coblenz, as no frontier is recognized and consequently no inspectors are in evidence at this point. There are 550,000 children being fed by the German Government. These are on the average two years under-size for want of proper nourishment.

"The economic situation is exceedingly bad. Transportation equipment is particularly depreciated. Every car in Germany has a flat wheel. Upholstering has been ripped from the car seats to be used for clothing. This is also true of household furniture. I did not see any of the paper suits in evidence, but paper belting is

being used in factories and is said to be as efficient and long lived as leather belting.

"I visited twenty-seven clay plants and three chemical plants during the period. The Krupp works at Essen employ about 38,000 persons engaged in manufacture of typewriters, sewing machines and similar peace-time products. Many ceramic plants are burning wood for fuel. All are operating at about 50 per cent capacity because of lack of fuel.

"The attention paid to detail in these industries is remarkable. Clays are floated in order to segregate the finest material and classify the remainder. One plant is using the ultra-violet rays over the clay solutions to kill the bacteria which would otherwise exert action to collect the iron particles and subsequently speck the wares.

"Several companies are engaged in making large quantities of stove tiles, a business entirely ignored in America. These artistic tile stoves are lined with refractory materials which hold the heat in the room. The tiles are pressed very soft in aluminum molds, insuring perfect cast pieces."

PLANT INSPECTIONS

Chicago industrial plants were visited as outlined below. The Western Electric Co. gave a complimentary luncheon on Tuesday and the Chicago Hardware Co. entertained the members in like manner on Wednesday.

BACH BRICK CO.

This plant is a typical example of distinctive methods employed in the manufacture of common brick in the Chicago district. The clay from the pits contains from 8 to 14 per cent combustible matter, and coal dust is sometimes added to assist in the burning. The clay comes from the cutter with practically no previous working, is stacked on iron cars and put through the waste heat driers. The cars are then run out to an open area, where the overhead crane with special hoisting grapples lifts the mass of brick from a car in one

operation and transfers it to the huge rectangular pile. Large quantities are stacked in a short time; the outside of the pile is walled over with a layer of burned brick and mud; oil burners are inserted in eyes near the bottom and the burning operation started. The finished brick are loaded directly from the pile to wagons and cars.

NORTHWESTERN TERRA COTTA CO.

This manufacturing plant involves methods of procedure combining the skill of artist and scientist to produce commercial wares. It is a huge art studio em-

FIG. 1. PARTLY FINISHED ORIGINAL DESIGN FOR THE WRIGLEY BUILDING, CHICAGO

ploying numerous designers and clay modelers on one hand and demanding application of the exact science of chemistry to finishing glazes on the other. This is immediately evident in the fact that 35,000 tons of clay is molded to special shapes each year. No stock pieces or molds are kept. Each order calls for new designs. And the glazes used require all the colors of the spectrum with all the infinitely delicate shadings and blendings so essential for an appeal to the artist's eye. Here the ceramist is in his glory.

The raw clay is brought in from the Indiana coal district by rail and mixed with suitable grogs depending on the ware desired. The clay sculptor with the aid of architect and pen artist produces the original design from which plaster of paris molds are made; these molds are sent to the casting room, where the required number of pieces are cast. Then the finishers tool out the imperfections by hand and work the finer clay to the surfaces.

The drying is carried on in ten Carrier Engineering Corporation chambers, where the air is conditioned from a temperature of 130 deg. F. and a relative humidity of 70 at the start to a temperature of 180 deg. F. at the finish. Taylor Instrument Co. instruments are installed for the proper control of the driers.

The glazes are sprayed on in some instances, but a large amount of work is done with the brush.

A spacious ceramic laboratory is equipped to control the scientific features and prepare new glazes. Fig. 2 shows an Isko refrigerating machine used for freezing a piece in the laboratory. When this is thoroughly chilled it is removed and subjected to a steam bath on one side and protected with an ice bath on the other—a rigorous test of glazes against climatic conditions. Abbe mills are used in preparing the glazes.

The burning operations employ thirty-five periodic kilns of the muffle type and eleven days is required for the burning cycle. Maximum temperature of about

1,050 deg. C. is reached. In addition a 320-ft. Dressler tunnel kiln has just been installed, increasing the capacity of the plant about 50 per cent. This kiln continuously turns out about eighteen industrial cars of ware per day and burns oil for fuel, reaching a temperature of 2,100 deg. F. in the hot zone. The estimated efficiency of fuel consumption is 75 per cent, against 10 per cent efficiency in the periodic kilns. The waste heat is conveyed overhead to the Carrier driers.

LINDSAY LIGHT CO.

The production of gas mantles from oxides of cerium and thorium nitrates burned to oxides is carried on after the method of the Welsbach Co. of Philadelphia, which was described in detail in the Oct. 15, 1919, issue of *CHEMICAL & METALLURGICAL ENGINEERING*, page 497. The monazite sands from Brazil are passed through an electro-magnetic separator to remove the iron and thence to the digesters, continuing through the same process as the Welsbach, with slight modifications.

COONLEY MANUFACTURING CO.

The production of enameled kitchen ware in this plant involves two distinct departments, namely, the fabrication of the metal shape, involving punching, drawing and annealing of sheet steel to shape, and the application of the enamel or "granite" coating to the piece. The first department is a series of large machine shops with a variety of presses and continuous annealing furnaces arranged to anneal the metal between drawing operations. Rapidly operated electric spot-welding machines are employed to attach handles and lugs to the various utensils.

The enamels are prepared dry in a battery of Abbe mills and subsequently mixed with water in the tanks

FIG. 2. TESTING GLAZE BY FREEZING

at the dipping benches. Women are employed for the dipping room work, which is done by hand. The mottled effect on granite ware is obtained by throwing a second color on with a coarse stipple brush and turning the piece in the hand while the splotches are still wet. Various trimming coats are given by brush or dipping.

The ware is placed in movable racks, which are later wheeled to the drier. The burning on is accomplished in a short space of time by introducing into coal-fired muffle kilns and removing almost immediately. Though most of the coating operation is hand work, the production is enormous.

The company is erecting a large steel and brick building which when equipped will double the plant's capacity.

WESTERN ELECTRIC CO.

Some idea of the extent of this mammoth Chicago concern may be gathered by an inspection of the power house which generates 150,000 kw. from steam turbo-generators. An increased capacity to a total of 200,000 kw. will be available when the new General Electric turbine goes into service. The total factory space is 3,000,000 sq.ft., devoted entirely to the manufacture of telephone equipment. There are 22,000 employees engaged in turning out 100,000 telephones per month, 400,000 switchboard lines per year of central office equipment and other commercial systems. The work is particularly rushing at this time due to the change over of the entire Bell telephone system to automatic central station control, which requires new apparatus with the present system maintained in operation during the period.

The cable plant turns out 250,000,000 conductor ft. of telephone cable, or 98 per cent of all the telephone cable produced in America.

The visitors were provided with a sufficient number of guides to give one guide to each four men—quite a departure from the ballyhoo usually attempted. Space will not permit an adequate description of this trip, but should manufacturers in general organize inspection trips as the Western Electric did in this instance the educational benefit to visitors would equal many months of study and be of inestimable value in our industrial development.

AMERICAN STEEL & WIRE CO.

This factory, like the Western Electric Co., conducts operations on an enormous scale. Billets 4 in. x 4 ft. of high- and low-carbon steel are received from the mills of the Chicago district as raw material. These are heated in furnaces and rolled to rods about $\frac{1}{4}$ in. in diameter which are handled as coils of wire. After pickling in muriatic acid and neutralizing with lime solution, they are annealed and ready for the drawing operations.

The company makes fence wire, copper, zinc and tin finished fine wire, wire fence, springs of all sorts, wire nails and baling wire. An interesting feature of the drawing operation is the use of a fermented rye meal solution for lubricating the wire just before it enters the dies. Details of the chemical control will be presented in a subsequent issue of CHEM. & MET.

CHICAGO HARDWARE CO.

This plant produces small castings and white glass table tops. It is the most successful manufacturer of small iron castings in the Chicago district and has an

elaborate department for making small and intricate cores.

After an evening at the outdoor opera in Ravinia Park, the meeting was concluded. The Chicago Section's hospitable entertainment was deeply appreciated by the visiting members.

Canada's Sugar Industry

There are three sugar plants in the Province of Ontario, two in Quebec, and one each in British Columbia, New Brunswick and Nova Scotia.

The amount of capital invested in the industry in 1918 for the whole of Canada was \$37,256,851, apportioned by items as follows: Land, buildings, and fixtures, \$17,733,990; machinery and tools, \$6,108,445; materials, stocks in process, finished products, fuel, and miscellaneous supplies on hand, \$6,511,626; and cash, trading and operating accounts, and bills receivable, \$6,902,790. The capital invested in Ontario plants was \$11,407,382; in Quebec, \$5,869,592; and in the remaining provinces, \$19,979,877.

The quantity and cost value at the works of the material used during 1918 are shown below:

Classes of Materials	Tons	Cost Value at Works
Beets.....	204,017	\$2,593,715
Raw sugar.....	313,651	39,991,144
Bone black and other materials.....		529,059
Boxes, bags, other containers.....		2,289,119
Total cost.....		\$45,403,037

The quantity and selling value at the works of the various products are shown in the following table:

Kinds of Products	Quantity	Value
Sugar, granulated, pounds.....	651,940,965	\$57,080,353
Molasses or sirup, gallons.....	1,559,694	1,016,626
Beet pulp, tons.....	11,069	411,645
Lime, bushels.....	22,590	6,250
Fertilizers, tons.....	1,284	43,075
Cattle food.....		151,776
All other products.....		102,494
Total value.....		\$58,812,219

"Colloiditis" Prevalent in Britain

FROM OUR LONDON CORRESPONDENT

London, August 9, 1920.

The use of the word "colloid" is at present being made an excuse and a catchword in the chemical industry and elsewhere, the uninstructed public having heard so much recently of progress in colloidal chemistry that any new project connected or presumably connected with it attracts undue attention. Even in the realm of "colloidal" fuel methods in which the fuel and oil are merely blended without the aid of a peptizing agent are being exploited by companies under names such as the Colloil Trust. Dr. Searle's recent book on "The Use of Colloids in Health and Disease" also suffers from the craze of applying the term "colloid" indiscriminately and the book was trenchantly and amusingly criticised in the *Journal of the Society of Chemical Industry* of June 30, p. 211R, by Dr. H. H. Dale. Thus Dr. Searle states that all products of digestion are essentially colloidal and, after previously stating that solutions of colloids do not pass through membranes, assumes that in the presence of common salt their passage is considerably increased. From this Dr. Searle deduces "the advisability of eating salt with so typical a colloidal gel as a boiled egg," but to quote Dr. Dale's criticism, "if salt will get a boiled egg through the alimentary mucous membrane, digestion becomes a mere hobby."

Program of Chicago Meeting, American Chemical Society

THE following is the final program of the general meeting, entertainment, industrial excursions and Industrial, Rubber, Fertilizer and Leather Divisions:

Monday, Sept. 6

- 4 p.m. Council meeting in Parlor B, University Club.
- 6:30 p.m. Councillors' dinner given by Chicago Section in College Hall, University Club.
- 8 p.m. Council meeting reconvenes in Parlor B.

Tuesday, Sept. 7

10 A.M.—GENERAL MEETING, GOLD ROOM, CONGRESS HOTEL.

Address of welcome by Prof. Julius Stieglitz, honorary chairman, in behalf of Chicago Section.

Address of welcome by Joseph R. Noel, vice-president of Chicago Association of Commerce, in behalf of Chicago business men.

Response for Society by Prof. William Albert Noyes, president American Chemical Society.

"The Value of Technical Training in the Reconstruction of Industries," by Thomas E. Wilson, president Wilson & Co., packers.

"Chemistry's Contribution to the Life Sciences," by Dr. A. S. Loevenhart, University of Wisconsin.

The directors of the Chicago Chemists' Club will entertain the directors and the advisory committee of the American Chemical Society at luncheon, club headquarters, 315 Plymouth Court.

The Association of Harvard Chemists will meet in the Green Room, Congress Hotel, for luncheon and the semi-annual meeting.

1:15 p.m. Take special elevated trains at Adams St. Station for Noyes St., Evanston. Badge admits to trains.

3 p.m. General meeting reconvened in Patten Gymnasium, Northwestern University campus, Evanston.

"The Relation of Educational Institutions to the Industries," by Prof. H. P. Talbot, Mass. Inst. of Tech.

"Some Uses of Silica Gels," by Prof. W. H. Patrick, Johns Hopkins University.

ENTERTAINMENT PROGRAM

4:30 to 7:30 p.m. Chicago Band concert on the campus.

4:45 to 5:30 p.m. Swimming exhibition in gymnasium pool.

5:30 to 6:30 p.m. Swimming in pool for men only. No suits required.

4:45 to 5:45 p.m. Organ recital in Fisk Hall by Hugo Goodwin.

5 to 6 p.m. Indoor-outdoor baseball game between Chicago section and the World. Captain—Chicago Section, L. V. Redman; the World, Charles H. Herty.

5:30 to 7:30. Dancing in the gymnasium.

4:45 to 5:30. Committee of Evanston women headed by Mrs. L. V. Redman and Mrs. W. Lee Lewis will serve punch at various stands on the campus.

6 to 7 p.m. Supper served on the lawn south of the gymnasium near the Shakespeare Gardens. Registrants are furnished with tickets.

4:30 to 7:15 p.m. Outdoor smoker.

7:15 to 9:30 p.m. Evening entertainment.

8 to 10:30 p.m. Observatory will be open for inspection of the universe.

Special trains start for the city from Noyes St. at 9:40 p.m., but regular trains run all night.

Wednesday, Sept. 8

DIVISIONAL MEETINGS, 9 A.M. AT UNIVERSITY OF CHICAGO

Copy of the *Chemical Bulletin* furnished to all registrants will give explicit directions for reaching this and other locations.

DIVISION OF INDUSTRIAL AND ENGINEERING CHEMISTRY

Session opens with a symposium on "Cellulose Chemistry," which will be led by Dr. J. J. Esselen of A. D. Little, Inc.

"The Constitution of Cellulose," Harold Hibbert.

"Economics of the World Pulp Situation," Hugh P. Baker.

"The Regeneration of Book Stock," Charles Baskerville and Clarence Joyce.

"Recovering of News Print," Charles Baskerville and Reston Stevenson.

"On the Cellulose Content of Certain Compound Celluloses," Louis Kahlenberg.

"A Comparison of Wood Cellulose and Cotton Cellulose," S. A. Mahood and D. E. Cable.

"Acid Hydrolysis of Sugar Cane Fiber and Cottonseed Hulls," E. C. Sherrard and G. W. Blanco.

"The Preparation and Analysis of a Catt's Food Consisting of Hydrolyzed Sawdust," E. C. Sherrard and G. W. Blanco.

"Supply and Preparation of Wood for the Manufacture of Pulp," Hugh P. Baker.

"Parchmentizing Paper and the Reaction of Mordants," J. E. Minor.

"Is It Feasible to Form a Section of Cellulose Chemistry?" G. J. Esselen, Jr.

"Solvents for Phosgene," Charles Baskerville.

"Electrometric Method for Detecting Segregation of Dissolved Impurities in Steel," (Lantern), Edward G. Mahin and R. F. Brewer.

"Soda-Lime for Industrial Purposes" (Lantern), Robert E. Wilson.

"Flow of Viscous Liquids Through Pipes" (Lantern), Robert E. Wilson and M. Seltzer.

"New Solvents for Rosin Extraction," H. K. Benson and A. L. Bennett.

"Comparative Study of Vibration Absorbers," H. C. Howard.

"Catalysis in the Manufacture of Ether," Hugo Schlatter.

"Use of Platinum Crucibles in Electro-Analysis. Copper Determination," Harold Van Doren and J. R. Withrow.

"Use of Platinum Crucibles in Electro-Analysis. Rapid Copper Determination," Rufus D. Rud and James R. Withrow.

"Estimation of Benzene in Admixture With Paraffine Hydrocarbons," H. McCormack.

"Preparation of Manganates and Permanganates," H. McCormack.

"Permanganate Determination of Sulphur Dioxide," H. S. Coith and James R. Withrow.

"Action of Permanganate Upon Sulphur Dioxide and Sulphides," F. C. Vilbrandt, Samuel L. Shonefield and James R. Withrow.

"Idiometric Determination of Sulphur Dioxides," Gordon D. Patterson and James R. Withrow.

"Uniform Packages for Reagent Chemicals," W. D. Collins.

"Uniform Specifications for Chemical Thermometers," R. M. Wilhelm.

"Recovery of Industrial Gases With Activated Charcoal," O. L. Bannebey.

"A Comfortable Dust Respirator," H. V. Main.

"Evidences of Auto Catalysis in the Hydrogenation of Cottonseed Oil," O. R. Sweeney and Joseph Elbert.

RUBBER DIVISION PROGRAM

Discussions, "Shall the Rubber Division publish an annual volume of reprints and lengthy abstracts of interest to the rubber chemists and the public during the year?"

W. B. Weigand, "Rubber Energy."

Research Laboratories, New Jersey Zinc Co., "The Aging of Some Rubber Compounds."

Research Laboratories, New Jersey Zinc Co., "Some Microsections Cut From Vulcanized Rubber Articles."

KENT LABORATORY
UNIVERSITY OF
CHICAGO

W. LEE LEWIS
CHAIRMAN CHICAGO SECT.

CONGRESS HOTEL
CONVENTION
HEADQUARTERS

Thos. E.
Wilson

Julius - Stieglitz
HONORARY CHAIRMAN CHICAGO SECTION

W.A. NOYES
PRESIDENT AMERICAN
CHEMICAL SOCIETY

W. H. PATRICK

HENRY P TALBOT

NORTHWESTERN
CAMPUS

A. S.
LOEVENHART

PATTON GYMNASIUM
NORTHWESTERN
UNIVERSITY

G. D. Kratz, A. H. Flower and B. J. Shapiro, "The Action of Certain Organic Accelerators in the Vulcanizing of Rubber (II)."

G. D. Kratz, A. H. Flower and B. J. Shapiro, "The Action of Certain Organic Accelerators in the Vulcanizing of Rubber (III)."

J. F. Schuffer, "Method for the Determination of Free Sulphur and Antimony Tri- and Penta-Sulphides in Golden Antimony."

J. B. Tuttle, "The Action of Heat and Light on Vulcanized Rubber."

Symposium, "The Analysis of Rubber," led by W. W. Evans.

Round table discussion of recent developments.

There will be samples on exhibition of rubber, vulcanized by Peachey's nascent sulphur method.

FERTILIZER DIVISION

"Kelp as a Basis of an American Potash Industry," J. W. Turrentine.

"Relationships of Chemistry and the Fertilizer Industry," C. H. MacDowell.

"A Perfect Fertilizer Law," E. G. Proul.

"Boron in Relation to the Fertilizer Industry," J. E. Breckenridge.

"The Quantitative Estimation of Borax in Mixed Fertilizers," J. M. Bartlett.

"Note on the Determination of Nitrogen in Fertilizers Containing Both Organic and Nitric Nitrogen," by F. B. Carpenter.

"Injurious Effects of Borax on Field Crops," F. B. Carpenter.

"The Changes Taking Place in Cyanamide When Used in Mixed Fertilizers," Rolla N. Harger.

"Dicyanodiamide. A Rapid, Direct Method for Its Determination in Cyanamide and Mixed Fertilizers," Rolla N. Harger.

"Some Results of Determination of Potash by the Lindo-Gladding Method of Using Alcohol of Various Strengths in the Presence of Sodium Salts," R. D. Caldwell and H. C. Moore.

"The 'Blank' in the Kjeldahl Process, Its Analytical and Commercial Significance," B. F. Robertson.

LEATHER SECTION

"Nature of the Hide-Tannin Compound and Its Bearing Upon Tannin Analysis," John Arthur Wilson and Erwin J. Kern.

"The Mechanism of Bating," John Arthur Wilson.

"Chemical Control of the Tannery," F. C. Orthmann.

"A New Method for the Recovery of Nitrogenous Fertilizer Material From Tannery Waste Sulphide Liquors," V. H. Kadish.

"The Influence of Acids on the Tannin Content of Tan Liquors," Alan A. Claffin.

"On the Swelling and Falling of White Hide in Vegetable Tan Liquors," George D. McLaughlin and R. E. Porter.

"Dyestuffs as Used in the Leather Trade," P. R. Roberts.

"The Effect of Concentration of Chrome Liquors in the Adsorption of Its Constituents by Hide Substance," A. W. Thomas and Margaret W. Kelly.

"The Determination of Hydrochloric Acid and Neutral Chlorides in Leather," A. W. Thomas and A. Frieden.

"Comment on Wilson and Kern's Recent Contribution to the Knowledge of Vegetable Tanning Agents," A. W. Thomas.

Luncheon arrangements have been made at the Edelweiss Gardens during the scientific meetings.

PLANT VISITS

1:15 p.m. Entrain at Van Buren and Randolph Stations, Illinois Central R. R., on special train, or catch same train at 57th and 60th St. stations at 1:30.

Doehler Die-Casting Co., maker of aluminum and white metal castings.

Pullman Car Works. Freight and assembly plants, where the "Ford plan" produces one every few minutes.

Sherwin-Williams Co. Visit the Dutch Process White Lead plant.

Carter White Lead Co. Making white lead by Carter process.

Libby, McNeill & Libby, Blue Island Cannery. Packing jelly, jam, mustard, olives, apple butter and catsup.

SOCIAL FEATURES

6:30 p.m. Alpha Chi Sigma fraternity dinner at Hotel Morrison.

8 p.m. "Chemical Publications," by President W. A. Noyes, Gold Room, Congress Hotel.

Thursday, Sept. 9

DIVISIONAL MEETING, UNIVERSITY OF CHICAGO

9 a.m. to 12 noon and 2 p.m. to 5 p.m. Division of Industrial and Engineering Chemistry will hold a Fuel Symposium arranged by A. C. Fieldner, Pittsburgh Station, Bureau of Mines, as follows:

"Low-Temperature Carbonization of Coal," S. W. Parr, University of Illinois; T. E. Layng.

"Carbonization of Canadian Lignite," Edgar Stansfield, chemist, Canadian Department of Mines.

"Efficiency of Various Fuels for Heating Houses," Henry Kreisinger, fuels engineer, Bureau of Mines.

"Byproduct Coking," F. W. Sperr, Jr., chief chemist, Koppers Company.

"Relation of Byproduct Recovery to Fuel Utilization and Economy," C. E. Lewers, Semet-Solvay Co.

"Use of Charcoal in the Extraction of Gasoline From Natural Gas," G. A. Burrell, president, Island Refining Co.

"Colloidal Fuels, Their Preparation and Properties," S. E. Sheppard, chemist, Eastman Kodak Co.

"Gasoline Losses Due to Incomplete Combustion in Motor Vehicles," A. C. Fieldner, supervising chemist, Bureau of Mines; G. W. Jones; A. A. Straub.

"The Enrichment of Artificial Gas by Natural Gas," J. B. Garner, Peoples Gas Co., Pittsburgh, Pa.

"Commercial Realization of Low-Temperature Carbonization of Coal," Dr. Harry A. Curtis, chief chemist, International Coal Products Corporation.

"Fuel Conservation, Present and Future," Horace C. Porter, consulting chemical engineer.

7 p.m. Semi-annual banquet, Gold Room, Congress Hotel. Evening dress optional. Tickets to registrants, \$4. Toastmaster, W. Lee Lewis. Speeches and music.

Friday, Sept. 10

INDUSTRIAL EXCURSIONS

Illinois Steel Co., South Works, blast furnaces, bessemer converters, electric furnaces, open-hearth furnaces, rolling mills and gas-engine plant operating on cleaned blast-furnace gas. Train leaves Randolph St., Illinois Central R. R., at 8:19 a.m. and Van Buren St. at 8:20 a.m.

The following trip which includes plants listed below starts from the LaSalle St. Station from 8:10 to 8:27 a.m. Albert Schwill & Co., maltsters.

American Maize Products Co., maker of cornstarch and byproducts therefrom, corn oil, dextrose, dextrin, glucose, etc.

Steel & Tube Co. of America, operator of Semet-Solvay byproducts coke plant and large tube mill.

American Steel Foundries Co., Indiana Harbor plant, maker of steel castings.

International Lead Co., electrolytic refiner of lead and electrolytic white lead.

Assemble at Congress Hotel at 1:30 p.m. for the following excursions:

The Fleischmann Co., maker of cider vinegar, malt vinegar, white wine vinegar and yeast.

National Malleable Castings Co., malleable iron castings.

Northwestern Terra Cotta Co., terra cotta and art decorations.

Fansteel Products Co., maker of pure tungsten and molybdenum.

Sears, Roebuck & Co., wallpaper and color plants. Leave at 1 o'clock and have luncheon at plant.

Heath & Milligan Co., manufacturer of pigments and mixer and grinder of paint.

Legal Notes

BY WELLINGTON GUSTIN

Seymour Mfg. Co. Obtains Large Judgment— Agreement Not in Restraint of Trade

The \$180,296.63 judgment in favor of the Seymour Manufacturing Co., of Seymour, Conn., against the Derby Manufacturing Co., of Derby, Conn., has been set aside by the Supreme Court of the state, for the purpose of correcting numerous errors, thereby changing the judgment, though such change is not substantial in the amount.

The case is involved, arising out of contract between the companies for the manufacture of copper bands for projectiles. The Derby company, with the financial aid of the Seymour company, built a plant adapted to the manufacture of these bands, and began operations with orders turned over to it by the Seymour company. It also attempted to go into business on its own account, but was unable to finance the purchase and carrying of copper, and turned to the Seymour company for assistance. The contract in question was entered into Jan. 29, 1917, and was terminated April 20, 1917, by mutual consent. At this latter date the Derby company was indebted to the Seymour company. The judgment was obtained by Seymour and Derby appealed. A number of questions arising out of the business relations of the parties were presented to the Supreme Court.

QUESTION OF LEGALITY OF THE CONTRACT

The first question was whether the contract was illegal on its face or because it was entered into for the purpose of restraining competition. It purported to be a contract to co-operate in the construction of copper driving bands on the basis of the Seymour company providing the copper and the Derby company manufacturing the bands therefrom. Each party engaged to fully inform the other of any impending business, and if it is proposed to bid for or accept any such business, and if the Seymour company can furnish the copper, and the parties agree on the market price of the copper and on the contract price for the bands, then the Seymour company is to make the bid or acceptance in its own name, and turn over one-half of the tonnage orders so taken to the Derby company for production. The Derby company agrees to take the Seymour company's copper, use it and to account for the scrap. The difference between the market price of copper per pound and the contract price of bands per pound is called the "toll" in the contract, and is to be divided in proportion of eleven parts to the Derby company and four parts to the Seymour company.

DEFENDANT CLAIMED RESTRAINT OF COMPETITION

Defending the suit, the Derby company claimed that this contract was illegal as restraining competition because the parties proposed to agree on the price of bands. The Supreme Court said this contract contained no present agreement on prices for any purpose. Though it does contain an agreement to agree on the price at which some bands shall be sold, this is not for the purpose of preventing one party from underselling the other in the open market. It relates only to orders or contracts brought within the contract by the specific

agreement of the parties in each case; and therefore applies only to orders which must be or may be, according as the contract is construed, turned over in part to the Derby company for production. Of course, said the court, the Derby company cannot bid against the Seymour company for any contract and at the same time agree to act as its bailee for hire in assisting to fill it. But this does not make such illegal at common law or under the Sherman anti-trust act.

The Derby company further contended that the contract is illegal because it agreed not to make any bid or take any order for bands. But the court failed to find anything in the contract prohibiting the defendant Derby company from accepting business on its own account. The contract goes no further than to provide that, so far as the parties may be able to agree on prices, the Derby company is to co-operate in production, and the bid or acceptance is to be in the Seymour company's name. It must follow, said the court, that if the parties cannot agree on the price at which any order will be accepted for co-operative production, either party may compete for it on its own account.

The claim that the contract was entered into for the purpose of restraining competition between the parties is refuted by the findings of the court that the Seymour company did not have productive capacity to fill its orders, and that the Derby company had surplus capacity for production, but did not have the funds or credit enough to carry on the business on its own account.

MINOR ERRORS IN THE JUDGMENT

There were numerous minor errors in calculating the amount of the judgment. The Derby company reported that it had made 288,283 bands under the contract. In making these it used not only the 500,000 lb. of copper furnished by the Seymour company at the agreed special prices, but also used 180,499 lb. of other copper belonging to Seymour, which was in the Derby company's possession. Acting on the theory that the Seymour company was bound to furnish copper for 500,000 lb. in bands at the specified prices, it credited the Seymour company with 30.5c. only for this copper, although its market value when appropriated was 35c. a lb. Defendant appropriated the plaintiff's copper to the contract without agreeing on its price, and the plaintiff relied on the implied promise of the defendant to pay what the copper was reasonably worth. The court said the copper was reasonably worth its market value at the time it was taken.

Again, one order, known as the "Chase contract" was to be carried out by the Derby company shipping and billing the bands direct to the Chase company, and reporting to the Seymour company the number of bands so shipped and paid for. There was an option in the "Chase contract" calling for an additional quantity of bands. The Derby company concealed the fact that the option had been exercised. It failed to report 73,830 bands which were delivered to the Chase company and paid for. Now, the Seymour company did not furnish the copper for these unreported bands, but it was at all times ready and willing to do so. The Chase contract was a co-operative transaction. The court said the Seymour company had the right to assist in its performance by furnishing the copper at agreed prices and the right to receive its agreed toll on all bands delivered and paid for. Conversely the Derby company had no right to resort to other sources of copper supply in order to make itself the sole beneficiary of the con-

tract. The Derby company claimed the agreed toll was payable only in case the Seymour company furnishes the copper. But the answer is that the latter's readiness and willingness to furnish copper is in law a sufficient performance of its agreement to furnish it, as against the defendant who has wrongfully prevented it from doing so.

Another important element of the case was the special damages claimed by the Seymour company in the delay of returning the copper scrap to it at the termination of the contract. The court held the Derby company was liable for the loss to plaintiff by its being compelled to buy additional copper through this delay in returning the copper scrap.

Court Holds Invention by Employee Not Within His Contract Assigning All Invention Rights

The White Heat Products Co. sought to compel its employee Charles W. Thomas to disclose certain inventions and assign to it an application for patent on such devices, pursuant to the terms of a written agreement between the parties. The case was heard before a referee, who found for the products company, holding that the invention was within the terms of the contract. After argument the trial court reversed the finding of the referee and dismissed the company's case, and now the Supreme Court of Pennsylvania has affirmed this decision.

The White Heat company is described as being organized for the purpose of making and selling products from silica and other materials, and at time of entering into the contract with Thomas it was engaged in the manufacture of bricks for wainscoting, etc., from white silica rock mixed with glass as a binder. Thomas was an expert in matters of this character and owner of certain patents, and, in consideration of the agreement of employment, assigned to the company all his interests in certain specified patents, together with the exclusive right to make, use and sell the design under another patent relating to a furnace "in so far as the same relates to the business of making bricks, stone products, earthenware products or analogous and collateral products," together with his "entire right, title and interest in and to every invention, interest therein, or claim thereto relating to the manufacture of bricks, stone products, earthenware products, and analogous and collateral products which he now has or may hereafter make or acquire during the period of his employment by said stoneworks and for one year after the termination thereof."

WORKED ON ABRASIVE WHEEL INVENTION

For a period of two years and ten months Thomas continued experiments in the manufacture of bricks and all patents secured by him were assigned to the White Heat Products Co. In 1914, the company's plant being idle owing to its operations proving unsuccessful, Thomas began of his own accord experimenting with a process for making an abrasive wheel to be used for grinding iron, steel and other hard metals. The experiments were at first conducted in a separate shop, but later the matter was discussed with P. M. Sharpless, president of the White Heat company, with a view to their engaging in business together, and it was agreed that experiments be continued at the company's plant and at its expense. The experiments proved successful and samples were put on the market.

Agreement over the manufacture of abrasive wheels was not concluded and the company then first claimed the invention was within the original contract of employment.

The first question presented to the Supreme Court was, Is a wheel used for grinding an invention "relating to the manufacture of bricks, stone products, earthenware products or analogous and collateral products" within the meaning of those words as used in the contract? Its answer was that it was not such an invention.

AGREEMENT MUST BE CLEAR AND UNMISTAKABLE

The rule of law is that in cases of this kind, where the product of an inventive mind is sought to be appropriated under an agreement to assign to another, the language of the agreement must be clear and show an unmistakable intention that the particular matter covered by the invention or patent is within the intention of the parties at the time of agreement.

The court said that measured by this rule the contract as viewed by the company falls down. It is as susceptible to one construction as another. The court was of the opinion that the contract provisions were limited to inventions relating to the manufacture of earthenware products and do not apply to or require the assignment of patents for the manufacture of all articles made of earth or clay; consequently a tool in the nature of an abrasive wheel, although composed principally of bauxite clay, is excluded from its terms as not coming within the meaning of the words "earthenware products."

There is another rule of law that where a person in the employ of another devises a new invention and uses the property of his employer and the services of other employees to put the device in practical form and assents to the use of the perfected invention by his employer, he thereby gives to such employer an irrevocable license to use the device. This was urged in favor of the company.

But the court said it did not apply, since the invention was conceived and the preliminary work done outside of the employee's working hours and in a plant not connected with his employer's plant. While the article was subsequently perfected and manufactured in the plant of his employer, still this was done under and subject to the completion of negotiations for a proper compensation to Thomas through the profits to be derived from the manufacture and sale of the patented article.

Judgment was therefore affirmed against the company.

Contract Where "Ton" Means 2,000 Lb.—Rule May Be Changed by Agreement or Custom

In an action by the Chemung Iron & Steel Co. against the Mersereau Metal Bed Co. on a sales contract in New York, the court there construed the term "ton" as used in the contract to mean 2,000 lb. and not a long ton of 2,240 lb., where the contract called for "tons" merely and not long tons and neither proof of trade customs nor otherwise was it shown that long tons were intended. In the circumstances, section 4 of the General Business Law must be held to govern. It reads in part: "The hundredweight consists of one hundred avoirdupois pounds, and twenty hundredweights are a ton." And where there is no agreement to the contrary, or a general custom of the trade does not change the rule, same must be applied.

A Study of Chain Driving

Report of Investigation and Tests on Chain Driving — Variable Factors Involved — Some Mathematical Relationships—Effect of Impact on Life of Chain —Economic Calculations

FM. LAWSON has made notable progress in the development of a chain driving theory in his recent contribution to *Engineering*, July 2, 1920, which, on account of its interest to the engineering profession, we are reproducing in full:

To a commercial mind, perhaps the first appeal of any proposition in engineering is with regard to the practical issues which are likely to result from its direct application. The commercial mind is not so much concerned with the theories involved, but prefers to examine them in the light of actual practice. The true theorist, on the contrary, prefers to commence from first principles, adopting as his base a point as in Euclid. From this beginning he sets down his proposition and deduces the facts which may be inherent although not always self-evident. He is content that the theory shall be subjected to the most careful scrutiny in its smallest detail, and is not satisfied unless the test of actual practice be applied in order that his conclusions may be proved to be sound.

TWENTY VARIABLE FACTORS

Research work connected with chain driving is undoubtedly difficult, since in any chain drive there are at least a score of variable factors, the alteration of any one of which may involve alteration of several others. The following gives twenty variable factors:

(1) Number of teeth in wheels; (2) revolutions per minute of wheels; (3) ratio of reduction; (4) inclination of drive; (5) material wheels made of; (6) steadiness of load; (7) speed of chain; (8) pitch of chain; (9) lubrication of chain; (10) pull on chain; (11) center distance; (12) inclination of chain; (13) type of chain; (14) design of chain; (15) length of chain; (16) tension on slack side of chain; (17) bearing pressures; (18) weight of chain; (19) accuracy of manufacture of chain; (20) accuracy of manufacture of wheels.

Looking at the above list, it will be observed that if one factor is altered and a different result obtained it will be impossible to say whether the difference is due to the original factor being altered or to one of those factors which is affected by its alteration. For instance, increasing the number of teeth in a driver wheel may give a longer life, but is this longer life due entirely to the number of teeth being altered? Is it not also due to the fact that by increasing the number of teeth the pull in the chain is decreased and the bearing pressure reduced? Or, again, would not the life have been increased still further if the alteration had not affected the speed of the chain?

Tests would have to be carried out *ad infinitum* to establish any definite theory, which in itself is an absurdity, so that if any theory can be outlined which will enable those engaged on practical research to direct and concentrate their energies along defined paths their time will be saved and progress made.

Now, to follow in Euclid's footsteps, what is the point common to all chain drives?

In considering a chain drive the simplest form may be stated to consist of a driver wheel, a driven wheel, and a length of endless chain, the utility of the chain being to transmit power from the driver wheel to the driven wheel. The chain consists of a series of links connected by studs, so that the center of all studs in the chain travel along the same path; consequently if the path of one stud can be definitely located, the paths of all studs at any position in the chain drive are located, and this stud path in its relation to the wheels is common to all chain drives and consequently may be considered as the starting point, for it is a line generated by a point.

Now a stud in a chain 1-in. pitch running at 500 ft. per minute moves a pitch length in $\frac{1}{100}$ second, so that it is impossible to see the path of any one stud although the light wave of the path of all studs may be observed under favorable conditions. The practical value of this light wave cannot be exaggerated, but it has one drawback for research in that it is not capable of measurement, and consequently a method had to be adopted to obtain actual stud paths at high speeds which could be measured. The method the author adopted, and it is a method which has the advantage of being simple, is as follows:

To one of the studs in a chain a stiff pointer was fixed extending about $\frac{1}{4}$ in. beyond the width of the chain. When the chain was running a board covered with beeswax was moved toward the chain so that the pointer scratched the path in the wax. In order to simplify the mechanism, records were taken separately at four different places:

(1) Entering the driver wheel; (2) leaving the driver wheel; (3) entering the driven wheel; (4) leaving the driven wheel.

In this paper the author has concentrated on the first division, knowing that if this is solved the three remaining divisions can be solved in the same way. Before dealing with these practical results it is necessary to investigate the theory, for, although chain drives have been on the market over thirty years, no satisfactory theory has yet been published, so far as the author knows, and consequently the following is the result of research:

MATHEMATICAL RELATIONSHIPS

The "true" pitch circle diameter of a wheel may be calculated from the formula:

$$\text{Pitch circle dia.} = p \operatorname{cosec} \alpha \text{ inches} \quad (a)$$

where p = pitch in inches

Tr = number of teeth in driver wheel
(or driven wheel Tn),

$$\text{and } \alpha = \frac{180}{Tr}.$$

Visible damage creates malgearing, and the greater the damage the greater the malgearing, and consequently the greater the impact. Summing this up, it appears as if damage accumulates at compound interest—thus, if a chain has increased in pitch 1 per cent during five years it will certainly have increased more than 2 per cent in ten years, and may quite conceivably have increased 2 per cent in six years. This compound interest may possibly be reckoned as constant for one type of chain, but the constant is hardly likely to be the same for a roller chain as for a silent chain; moreover, it may vary with the pitch of the chain. There appears at present to be no method of arriving at this constant except by the lengthy process of testing.

Some useful purpose will be gained by arriving at a comparative life formula for any one chain with varying numbers of teeth in the wheels. Such a formula will be useful in determining the commercial value of the number of teeth in a wheel.

Damage done per minute to the studs is proportional to the impact blow \times number of times it occurs per minute.

— $2f \sin \alpha \times NTr$, using formula (m).

N being the r.p.m. and f the pull on the chain.

Life of the chain varies as

$$\frac{\text{Number of studs}}{\text{damage per min. to the studs}}$$

$$\text{If } L = \text{length of chain, number of studs} = \frac{L}{p}$$

$$\therefore \text{Life of chain varies as } \frac{L}{2f \sin \alpha NTr}$$

$$= \frac{L}{2fpNTr \sin \alpha}$$

Now the drive is given, $\therefore f \times$ speed of chain is constant

$$\therefore \frac{fpN}{12} Tr \text{ is constant, using formula (c)}$$

\therefore Life of chain for a given drive varies as

$$\frac{L}{\sin \alpha} \text{ where } \alpha = \frac{180}{Tr} \quad (s)$$

EXAMPLE

A 10-hp. drive, 600 r.p.m. to 200 r.p.m., centers 4 ft., chain 1 in. pitch. Which drive is the best commercial proposition, the drive arranged with 15T and 45T, making the cost of the drive \$100, or a drive having 20T and 60T costing \$120. Length of chain for the 15T drive, say, 126 in. Length of chain for 20T drive, say, 136 in.

Life of 15T drive : life of 20T drive :: 126 cosec 12 deg. : 136 cosec 9 deg. :: 603 : 870, making commercial value of life \$100 : \$145, whereas cost of 15T drive : cost of 20T drive :: \$100 : \$120.

Hence the 20T wheel drive is a better commercial proposition.

It must, of course, be borne in mind that there is a limit to the number of teeth which can be used, for, when a chain wears, it gets out of gear quicker with a large wheel than a small one.

This question of damage by impact opens up a strong case for small wheels being of the same hardness as the portion of the chain which engages with the wheel.

Thus in the case of roller chain wheels with only a few teeth, these should be hardened, since the roller of

TABLE IV. TESTS CARRIED OUT AT THE WORKS OF MESSRS. HANS RENOLD, LTD., MANCHESTER

*In test No. 3 the point was attached to the rear stud of outside link. In all other cases it was attached to forward stud on outside link.

the roller chain is hardened, but in the case of small wheels for chains in which unhardened links engage with the wheels, it is probably sounder policy to have a mild steel wheel unhardened.

Mention has already been made of the method adopted to record on wax the actual path of a stud. Particulars of a few of these tests are given in Table IV, and the salient points reproduced in Table V.

Tests 1, 2 and 3 may be grouped and termed lubrication tests, since the only altered factor between Nos. 1 and 2 was oil, and between Nos. 2 and 3 the only

TABLE V

alteration was that the chain was reversed so that the point scribed the path of the stud at the rear end of the outside link.

Much valuable information can be obtained from these three stud paths. In the first place (test 2) the stud path leading up to the wheel assumed a straight line when the chain was oiled, whereas when the chain was bone dry (test 1) the path showed a series of arcs with slightly rounded joints. Secondly, when the pointer was placed on the rear stud of the outer link (test 3) the path showed a straight line finishing off with one arc before entering the wheel.

The only possible explanation for the difference in path before and after oiling lies in the theory that lubrication supplied the necessary elasticity. Formula (r) gives the necessary elasticity in this case to be 0.0022 in.—which elasticity in test 2 might be provided by oil in any one of the following four places:

- (a) Between tooth of wheel and roller of chain.
- (b) Between roller and bush.
- (c) Between bush and stud in engagement.
- (d) Between bush and stud behind engagement.

Thus it appears that each film of oil supplied 0.0006 in. of elasticity.

In order to test if this theory was correct, test 3 was tried, since lubrication could not affect the rear stud path of an outside link when this was one pitch in distance

FIG. 4. STUD CENTER PATH

from engagement. The result here proved the case, the path being a straight line ending with an arc before engagement with the wheel. The measurement of this arc, i.e., 80 per cent of the pitch of the chain, should be noted—the probable explanation lies in the fact that the rear stud continued to drop until the forward stud reached the point of action.

IMPACT TESTS

Nos. 4, 5, 6, 7 and 8 may be termed impact tests, and would have been more complete if they had been duplicated with the pointer on the rear stud of the outside link, and if the horsepower could have been accurately measured.

All these tests were severe—a 10T driver wheel and chain speeds varying from 560 ft. per minute to 1,500 ft. per minute.

Tests 4, 5 and 7 had no appreciable load, and speeds alone were varied. The effect of impact was clearly marked on the stud path, the stud being actually "thrown" by impact off the pitch circle path. In No. 4 test it was thrown for 20 per cent of the pitch arc; in No. 5 test for 30 per cent of the pitch arc, and in No. 7 for 55 per cent of the pitch arc. No. 8 test gave the same result as No. 5, which might be expected, since the only alteration was a slight increase in horsepower which could not be accurately measured. Test 6 was similar to test 7, the only difference being a considerable increase in horsepower transmitted. The length of the throw path was considerably less, having decreased to 33 per cent of pitch arc from 56 per cent.

In none of these tests were there any signs of arcs in the path leading to the wheel, but in every case the path dropped to the point of impact. If formula (r) is applied to tests 4 to 8, it will be found that the elasticity required is 0.0096 in. Before considering how this elasticity is provided it is advisable to state the two facts that have been established by these five tests.

1. Impact can throw a stud off its normal path.
2. To some extent the length of the throw varies with the speed and inversely with the pull of the chain.

In tests 1, 2 and 3 it was found that lubrication provided 0.0022 in. of elasticity—possibly, from the fact

that tests 4 to 8 were run with 1½-in. pitch chain, whereas tests 1 to 3 were run with 1-in. pitch chain, it might be argued that more elasticity could be expected, but a detail investigation of the throw path proves that, if the stud can be thrown off its path, elasticity is not necessary to the extent provided for in formula (r).

LUBRICATION STUD PATH TESTS

In Fig. 4, let AQ'S represent the throw path, A being the point of impact.

Now the length of the line AQ'SD is greater than the length of the line AQ'SD.

Hence the stud path speed is greater from the point A than is represented by speed (b).

But

$$\frac{\text{Speed (b)}}{\text{Speed (c)}} = \frac{180^\circ}{\pi \sin \alpha}$$

which is constant for any given wheel.

Hence if speed (b) is increased by impact, speed (c) is increased in the same proportion.

But the straight stud path is straight, hence the straight speed must be greater than that supplied by speed (c). In other words, the effect of the throw path is equivalent to increasing the pitch circle diameter, which, in turn, increases the straight speed and so reduces the difference between speed (b) and speed (c).

It is thus obvious that if sufficient elasticity cannot be supplied by the chain and wheel either a throw path must exist, or else the chain in the straight will "pitch arc."

It must be noted from these tests, 4 to 8, that the length of the throw path varies, that, in fact, it increases with the speed of the chain and decreases with the load. It must also be noted from Fig. 4 that when the center of the stud is on the throw path it is not in gear with the wheel and does not come into gear with the wheel until it reaches the point S, hence action commences at S.

This explanation accounts for the reduction of length of throw path in test 6, as compared with test 7. No. 7 test was taken with the chain running with practically no load so that it was only necessary for the wheel to impart a short push during the period of reaction and before the second period of inaction commenced.

In test 7 the second period of inaction commences at a point which corresponds to 79 per cent of the pitch arc, whereas owing to the light load the period of action only commenced at a point corresponding to 56 per cent of the pitch arc. In test 6 the load was increased and the period of action started at a point equivalent to 33 per cent of the pitch arc.

When the speed is high and the number of teeth in a wheel is so low that a throw path exists, the effect on the chain is what may be described as vibratory whipping, this whipping being caused by a series of jerks from the teeth of the wheel. Whipping may exist owing to an impulsive load, but these two types of whipping can usually be distinguished by their frequency and depth—the impulsive load type being less frequent and of greater depth.

ARCHED LINK TESTS

Tests 9, 10 and 11 were carried out with the arched link type of chain (commercially known as noiseless or silent type). The characteristics of these paths is in the easy curve at the point of impact—thereby showing that impact is absorbed gradually. A brief look at the

design will show that the arch link when subjected to a sudden load can supply elasticity by elongation and that the effect of this elongation is to produce gearing at that part of face of link furthest from the stud center. This means more gradual engagement and explains the reason for this design being, under normal conditions, quieter than the roller design. Lubrication also supplies elasticity as in the roller tests.

Test 12 was carried out with a load which gave a very low factor of safety—the stud path is most instructive—without resorting to the wax board it was easy to see the light waves throughout the length of chain between driver and driven wheel. It will be noticed that this wave is similar to that obtained in No. 1 test (i.e., when lubrication was absent), but in No. 12 test oil was being pumped into the chain; however, the bearing pressure on the studs was so great that oil could not reach the surface.

These few tests are given to show that the practical results obtained agree with the theory, and that having established a portion of the theory the complete theory can be developed together with the practical stud path tests. For the value of the stud path test is one which no firm of chain makers can afford to overlook.

CHAIN CURVE

Before closing the subject it is necessary to place on record a few notes connected with the chain leaving the driver wheel, entering the driven wheel, and leaving the driven wheel.

When a chain is running at a fairly high speed with wheels having a small number of teeth, it will be observed that it takes an inward curve after leaving the

FIG. 5. CHAIN CURVE

wheel as shown in Fig. 5. This can be seen in both cases, i.e., leaving the driver wheel or leaving the driven, and is accounted for by the fact that the speed (b) is greater than the straight speed (c). In consequence, since the chain cannot alter from one speed to another instantaneously, it is necessary for it to assume a curve whose function is deceleration.

The same theory can be applied to the chain entering the driven wheel as has already been applied to it entering the driver wheel. The speed has to increase from speed (c) to speed (b)— T_n being of course inserted in obtaining the value of α . This speeding up occurs by impact supplied from the driven wheel, and since there is no load being transmitted and the chain is slack the throw path will be found to be so serious as to prevent a very slack chain being run at a high speed with a small driven wheel, since the chain will then get thrown out of gear with the wheel.

American Export of Dyes and Dyestuffs

The total amount of dyes and dyestuffs exported from the United States during the calendar year 1919 amounted in value to \$17,084,435, of which Japan imported \$3,196,550 and Canada, \$2,148,097.

German-French Potash Negotiations

"The result of the war has broken the former German world monopoly of potash, since by the terms of the peace treaty the thirteen Alsatian works have passed into the control of the French State," says the *Frankfurter Zeitung* for June 30. Although the output of Alsace, as compared with that of Germany, is relatively small, it is nevertheless important enough to affect prices on the world market. During 1919 Alsace produced 40,000 metric tons of potash, while it is expected that the output for 1920 will be five times that amount. The total sales of the German potash syndicate during 1919, in which 198 works participated, amounted to 812,000 metric tons of K_2O , and the output is capable of great development. Concerning this newly arisen competition the *Zeitung* says:

Neither in France nor in Germany has the state or the producing industry any interest in spoiling prices on the world market by competition. In view of present economic conditions it is to the benefit of both countries to develop their export at the best possible prices. An agreement between France and Germany as to potash prices on the world markets would therefore be to the advantage of both. At a recent general meeting of the Deutschen Kaliwerke a. G. it was reported that negotiations were then going on with France with the object of coming to an agreement regarding the Alsatian potash industry. The result of the negotiations cannot yet be foreseen; however, the economic interests common to both countries should be strong enough to overcome present objections and difficulties. It must not be forgotten that sooner or later Spanish potash will appear on the world markets. Also that overseas sales are not being made easier by the substitute industries which are being founded, as an example in the United States.

The chairman of the Deutschen Kaliwerke a. G. reported that sales are still slack. On political grounds, and in consequence of the unfavorable state of their currencies, sales to Poland and Czechoslovakia have almost entirely ceased. This is the more regrettable as sales to Poland in normal times are estimated at about 1,000,000 double centners (about 110,000 short tons) of pure potash.

Shark Fishing in Lower California

The shark-fishing industry is becoming increasingly important in the Ensenada consular district. The Lower California shark, known locally as the dogfish shark, is from 4 to 5 ft. long and weighs from 90 to 125 lb. The fishing is usually done by individual fishermen working out from camps on land. The fish are caught on long set lines, on which are fifty to one hundred hooks baited with small fish or lumps of shark meat. These lines are secured to floats, and the fisherman visits the lines daily to remove the catch.

The fins are sold for consumption by Chinese in shark-fin soup. The liver is boiled down and shark oil rendered out; each liver gives an average of 1 gal. of oil. This oil is used in paints and as a leather preservative. The remainder of the fish is dried and made into fertilizer or chicken feed. The skins are not utilized, except for fertilizer. Frequently shark steaks are sold by Chinese under the name of grayfish.

The large canneries operating fish-fertilizer plants in San Diego, Cal., are eager to buy shark, and the newly finished plant at Sauzal, Lower California, expects to specialize on converting shark into fish-meal fertilizer. Whereas formerly sharks caught in nets were separated from the more valuable fish and returned to the water, they are now brought ashore, although the demand is not yet sufficient to warrant using nets for sharks exclusively.

Studies of the Macrostructure of Cast Steel

Simple and Reliable Procedure Is Outlined for the Development and Record of Macrostructure—A Peculiar Banded Structure Is Described—Symmetrical Arrangement of Dendrites Is Necessary for Consistent Physical Tests—Pouring Cold Metal Suppresses Dendrites

By FRED G. ALLISON AND MARTIN M. ROCK*

WE HAVE wondered for a long time why it is that a larger number of the host of investigators in the field of metallurgy have not given more attention to the many easily observed but as yet unexplained phenomena which occur in the steel foundry. This may be due in part to the fact that experimenting with molten steel is too large a task for the laboratories of the average educational institution and in part to the fact that the attention of the foundry metallurgist is very largely absorbed with problems of immediate production. Whatever the cause may be, it seems that the steel foundry offers exceptional opportunities and a fertile field to the research metallurgist.

In his paper on "The Elastic Development of Steel," published in *CHEMICAL & METALLURGICAL ENGINEERING* of April 14, 1920, Sidney Cornell expresses the view that it would be a step toward betterment in the art of heat treating steel if more experimenters would simply publish observed facts without waiting for the development of completed treatises. We are in hearty accord with this view not only as it applies to the heat treating of steel but also in its application to the subject matter of this paper. Our observations on the macrostructure of cast steel are decidedly incomplete and the conclusions only tentative, yet they have seemed sufficiently interesting to justify this presentation.

RECENT PUBLICATIONS BY HUMFREY, LE CHATELIER AND BOGITCH

Interest in the macrostructure of cast steel was first aroused through the study of its microstructure and especially by the fact that the picric acid structure is apparently only slightly changed by what is known as a straight anneal. This interest was, however, greatly stimulated by two recent papers in the technical journals. One of these is by J. C. W. Humfrey¹ in the *Iron and Steel Institute* (1919) and the other by H. Le Chatelier and B. Bogitch² in *Revue Metallurgie*, vol. 16, No. 2, March-April, 1919.

Le Chatelier and Bogitch note the strange difference between the transitory and easily modified structural appearances caused by carbon and observed at relatively high magnification, and the entirely independent structural features observable by the naked eye—features which are extremely stable and almost unstudied, despite their industrial use in identifying steels of quality. They melted electrolytic iron in a closed silica tube under 3 or 4 cm. pressure of hydrogen, with or without additions of phosphide. Stead's reagent, Heyn's reagent, an iodine reagent (iodine 10 g., KI 20 g., H₂O 100 c.c.)

and boiling acid did nothing to such samples except tone the allotriomorphic ferrite crystals differently. On the other hand, if electrolytic iron, with or without additions of chemically pure iron sulphide, iron phosphide, iron oxide, manganese or silicon, be melted in a gas furnace, any of these reagents will reveal marked chemical homogeneity unrelated to the ferrite crystals. Stead's reagent as modified by Le Chatelier and Dupuy (95 per cent ethyl alcohol 100 c.c., water 10 c.c., cupric chloride 1 g., picric acid $\frac{1}{2}$ g. and hydrochloric acid 1 to 3 c.c.) gives exactly reverse action to the other reagents, as comparative studies on the same section prove.

That such differential etching is due to oxygen only is proved by the method of melting, by the fact that

FIG. 1. TENSILE TEST-BAR, RISER, AND METHOD OF GATING AS USED BY THE AUTHORS

an annealing in hydrogen produces a superficial immunity. Comparing the action of Stead's reagent on steels with constantly increasing oxygen content, the authors advance their conclusion that this reagent attacks parts poor in oxygen, while the others eat into parts rich in oxygen.

The black marks made on bromide paper moistened with 2 per cent H₂SO₄ when in contact with steel are said to be due to sulphur only, since no markings occurred when testing any of the sulphur-free melts. Again, fumes from dissolving cast-iron filings will blacken such paper, yet if they are first bubbled through lead acetate they are without effect, and the lead precipitate upon analysis will be found to contain sulphur.

In his paper on "Macro-etching and Macro-printing" Humfrey recommends polishing the specimens with emery cloth, etching deeply with a 12 per cent aqueous solution of cupric ammonium chloride, to eliminate tool marks and surface hardening.

Etching is continued by the reagent cupric ammonium chloride 120 g., concentrated hydrochloric acid 50 c.c. (more or less), water 1,000 c.c., by pouring on fresh additions at intervals. Deposited copper can readily be

5

wiped off; in case examination reveals insufficient attack it should be resumed first with the neutral reagent. The strong relief is brought out by light buffing, and recorded by printing the etched surface on engraver's proof paper with printer's ink. A first trial of this procedure proved so satisfactory and so much superior to all other methods for developing the macrostructure that the studies were continued with renewed interest. The method is simple, rapid, requires very little apparatus, and the etched surfaces withstand rough handling.

DEVELOPMENT OF MACROSTRUCTURE

We polish the specimens to 000 emery cloth, immerse while still warm in the 12 per cent neutral solution of cupric ammonium chloride until a rather heavy and somewhat flaky deposit of copper is formed, transfer to a second vessel containing some of the same solution to which has been added about 5 or 10 per cent HCl and allow them to remain for from 15 to 30 min. After washing and drying, the etched surface is cautiously polished with crocus cloth. If the deposit of copper is too light, the acidified solution causes it to adhere firmly, giving a final brassy appearance which is difficult to remove, especially in the case of alloy steels. If examination shows that the etching has not been carried far enough to develop the structures to the desired depth, the treatment is repeated as before without regrinding. The temperature of the etching reagents greatly influences the speed of their action, but it is difficult to go far wrong. No special difficulty was experienced in etching nickel and other alloy steels by this method.

Instead of printing the etched surfaces with ink it is found very convenient to photograph them with an ordinary camera equipped with an enlarging lens and a Silverman illuminator, attached closely in front of the lens to give vertical illumination. Photographic contrast may be increased by rubbing the etched surface with a moistened portion of the crocus cloth, an action which deposits some of the rouge paste in the indentations, where it absorbs light. After allowing a few moments for the paste to dry, the specimen is again gently polished. Many specimens were 1 in. in diameter and gave excellent photographs when enlarged four times—in fact, the macrographs here given were originally photographed at four diameters but for printing convenience are reduced to about $2.3\times$. The method of photographing etched sections at low magnifications described by Foley⁴ or the similar method described by Monypenny⁵ should prove very satisfactory for specimens of this sort.

Although the method of photographing macrostructures is considered superior for some purposes to printing them directly on paper as described by Humfrey, the study of these structures can very profitably

⁴CHEM. & MET. ENG., Aug. 1, 1919, vol. 21, p. 140.

⁵CHEM. & MET. ENG., May 12, 1920, vol. 22, p. 382.

be undertaken without printing of any sort. Examination of the etched sections with a simple hand lens, such as is commonly used for the examination of fractures, is in many respects the most satisfactory method. The entire process is so simple that, as Le Chatelier and Bogitch state in the article referred to above, it seems surprising that the structures revealed have not been studied more in the past. Etching by this method might very well be included among the first laboratory exercises accompanying a systematic study of metallography.

WHAT DOES DEEP ETCHING REVEAL?

Deep etching of steel has been employed by investigators for many years, but the exact nature of the structures developed seems still to be in some doubt. Stead's and other similar reagents, which are said to show phosphorus segregation, give effects which are practically identical with those produced by Humfrey's and similar procedures. The so-called sulphur print also shows about the same structures. According to Humfrey the etching reagents dissolve most those portions of the metal which solidified first. From the results of their very carefully conducted experiments Le Chatelier and Bogitch, on the other hand, draw the conclusion that the heterogeneity is caused by oxygen in some state of combination—viz., FeO , FePO_4 , etc.

A large number of the specimens which we have examined were obtained from the standard tensile test-bar and its riser which the George H. Smith Casting

Co. is using at the present time. A sketch of this test-bar with riser and method of gating is shown in Fig. 1. The mold is made in two parts in a core box and is cemented and baked in the usual way. For the tensile test the cylindrical portion is cut off with a power hacksaw and machined to standard size, leaving the ends about $\frac{1}{4}$ in. in diameter. This pattern gives a solid test-piece which can be machined to size with a minimum of effort.

BANDED AND LATTICE-LIKE STRUCTURE

Among the first specimens which we etched with Humfrey's procedure were three broken tensile test-bar stubs from a small experiment which we conducted

TABLE I. PHYSICAL PROPERTIES OF "CELA" TEST-BARS

Test-Bar No.	Additions of "Cela," per Cent	Yield Point, lb. per Sq. In.	Tensile Strength, lb. per Sq. In.	Elongation in 2 In. per Cent.	Reduction of Area, per Cent.
1	None	43,500	73,500	29.5	50.1
2	None	42,740	74,300	30.5	48.6
3	0.10	45,500	74,250	30.0	33.4
4	0.10	44,140	74,350	32.0	50.0
5	0.15	45,750	74,000	30.0	48.1
6	0.15	44,090	74,700	29.5	42.5

with "cela" (cerium-lanthanum alloy) as a deoxidizing agent for converter steel. Six test-bars of the type shown in Fig. 1 were cast from a small ladle of a heat analyzing as follows: Carbon 0.22, silicon 0.45, sulphur 0.070, phosphorus 0.063, manganese 0.69 per cent. To two of these bars no "cela" was added; to the second pair enough was added to make about 0.10 per cent,

FIGS. 8 TO 13

Fig. 8. Hot-poured steel, mold jarred during solidification.

Fig. 11. Same as Fig. 8 after annealing 5 hr. at 1,832 deg. F.

Fig. 9. Hot-poured steel, quietly cooled.

Fig. 12. Same as Fig. 9 after annealing 5 hr. at 1,832 deg. F.

Fig. 10. Cold-poured steel.

Fig. 13. Same as Fig. 10 after annealing 5 hr. at 1,832 deg. F.

and to the third pair enough to make about 0.15 per cent. Although no special observation was made at the time, it is thought that the molten metal was very hot. These test-bars were all heated for four hours at 1,650 deg. F., (900 deg. C.) and cooled slowly in the furnace. The tensile tests, made by two different firms of inspecting engineers, are given in Table I. Although these data are not given especially for that purpose they show that the "cela" conferred no evident benefit.

The broken stubs from test-bars No. 1, 3 and 5 were cut about 1 in. from the large end and the structures developed are shown in Figs. 2, 6 and 7 respectively. The photographs show the entire end of the bars, the indentations at the circumference being caused by the jaws of the tensile machine.

The banded dendrites and lattice-work structures seen in Figs. 2 and 7 are interesting, to say the least. At first glance they suggest massive slip lines, perhaps due to the combined forces in the tensile machine, but no evidence supports such a suggestion. Fig. 6 (a section of bar No. 3) shows only the expected radial arrangement of the dendrites. This bar, however, showed the lowest reduction of area of any in the lot and it is possible that there is some connection between these facts.

Fig. 3 shows a second section through bar No. 1, a short distance from that shown in Fig. 2, and Fig. 4 is a longitudinal section through part of the same piece. The banded dendrites and lattice-work structure evidently extended throughout this cylindrical part and in all planes. In examining Figs. 2, 3, 6 and 7 it should

FIG. 14. TEST COUPON POPULAR AMONG STEEL FOUNDERS

be remembered that only a small amount of metal, perhaps $\frac{1}{8}$ in., was removed by the lathe. Fig. 5 shows a portion of the riser from test-bar No. 1. Here a tendency toward the banded structure is seen near the point at which the cylindrical part was attached (lower edge of figure). In the main, however, the riser shows the dendrites at right angles to the surface of the mold. The peculiar structures found in these test-bars may have been caused by deformation of the normal radial dendrites during the mushy stage. The tensile tests show that their quality was unimpaired. It may be worth noting in this connection that hot cracks in

steel castings sometimes show banded dendrites similar to those of Fig. 2. Their appearance has been usually attributed to exudation of the semi-fluid metal.

MACROSTRUCTURE OF COLD-POURED METAL

Writing of the elements of fiber, Howe¹ states that "The conditions which favor the dendritic form are rapid and quiet solidification." It is well recognized by steel foundrymen that it is difficult to refine the structure of a casting which has coarse dendrites and that the simplest way to avoid this difficulty is to pour the metal at the lowest practicable temperature. These thoughts prompted us to make the following experiment.

Three test-bars of the type shown in Fig. 1 were cast from a small ladle of a heat of converter steel which analyzed as follows: Carbon 0.37 per cent, silicon 0.42 per cent, sulphur, 0.063 per cent, phosphorus 0.056 per cent, manganese 0.72 per cent. The first of these three test-pieces was poured with the metal very hot (no pyrometer was used) and the board beneath the mold

FIG. 15. CROSS-SECTION OF TENSION TEST-PIECE MADE FROM COUPON SHOWN IN FIG. 14

was pounded continuously during solidification with an air rammer. The second was also poured with hot metal, but allowed to solidify quietly. Pouring of the third was postponed until the metal in the ladle was as cold as possible and still flow into the mold, too cold for practical work with small castings. Sections of these three cylindrical bars were cut at about $\frac{1}{2}$ in. from the end before they were annealed and their macrostructures are shown in Figs. 8, 9 and 10. Fig. 8 shows the specimen which was cast with hot metal and vibrated during solidification, Fig. 9 the one which was cast hot and allowed to solidify quietly and Fig. 10 the one which was poured with very cold metal.

The main portions of these bars were then annealed by heating to 1,832. deg. F. (1,000 deg. C.), holding for five hours and cooling slowly in the furnace. Sections were again cut about $\frac{1}{2}$ in. from the previous ones and their structures are shown in Figs. 11, 12 and 13. Fig. 11 shows the annealed structure of a section close to the unannealed section in Fig. 8. In like manner Fig. 12 goes with Fig. 9 and Fig. 13 with Fig. 10.

The zones of dendrites located about half way between the center and periphery in Figs. 8, 9, 11 and 12 continue into the riser in a similar manner. Jarring of the metal during solidification seemed to produce no effect, although the small size of the casting and probable rapid solidification may be responsible. Although the

annealing treatment was much more vigorous than would ordinarily be used in a steel foundry, diffusion was quite imperfect. The smaller branches of the dendrites disappeared, and the grain size, if it may be so called, in the non-dendritic areas seems to have enlarged somewhat. Although the photographs do not show it very well, the grain or crystal boundary lines in the annealed specimens are indefinite and show that diffusion was in progress. The comparative effect of hot and cold pouring is shown very clearly. The gas cavities shown in Fig. 10 are such as usually occur when steel is cast at too low a temperature. Close to these gas cavities there are small areas which seem to consist of very small dendrites. Just what causes them might develop into an interesting question. The test-bar corresponding to Fig. 12 gave the following tensile test: Yield point 48,500 lb., tensile strength 84,750 lb., elongation in 2 in. 22.5 per cent, reduction of area 30.8 per cent.

STRENGTH AS AFFECTED BY SHAPE OF COUPON

A number of tests were conducted with different heats to find out if the casting temperature would affect the tensile strength. The standard test coupon, shown in Fig. 1, was used, but the results thus far are inconclusive. It seems probable that our failure to find the expected difference in every case may be due in large part to the shape of the bar as cast. With this cylindrical shape, cast hot, there is frequently an area in the center with a network or "delta" structure, and that is really the portion which is tested. Moreover, with a normal radial arrangement of dendrites reaching uniformly to the center, the machined test-bar would have a "balanced" strength on all sides. Previous experience with many different types of tensile test coupons has indicated that this matter of "balanced strength" is very important.

Fig. 14 shows a type of test-piece or coupon which has been used extensively by steel foundries. Several slices suitable for machining into tensile-test bars may be cut from each piece. Fig. 15 shows the macrostructure of a cross-section of a tensile-test stub made from the first cut of such a coupon, cast with hot metal. An examination of this figure shows very clearly the side at which it was attached to the main portion. Test-bars which show this arrangement of dendrites, when placed under tension, frequently develop incipient cracks along one side before breaking. Such test-bar stubs may be etched with copper reagents without further polishing and there seems to be a definite relation between the incipient cracks and a coarse macrostruc-

ture. As a rule, the second cut from this style of test coupon gives a poorer tensile test than the first cut.

In the study of the effect of casting temperature, many sections of the cylindrical bars and V-shaped risers, cast with hot and cold metal analyzing about 0.25 per cent carbon and 0.70 per cent manganese were examined. Although exact temperature readings were not taken and the structures varied somewhat, Figs. 16 and 17 show typical hot and cold structures of 0.25 per cent carbon steel. These figures were derived from the risers and are from the same heat. Fig. 18 shows a small dendritic area entirely surrounded by non-dendritic. This particular area was located near the top of a riser. Fig. 19 is a section through the end of a small casting. Both of these figures show again that the growth of dendrites does not always start at the surface of the mold.

A study of sections of variously shaped castings shows that if the flowing metal passes through a long channel it is sufficiently cooled by contact with the mold surface to greatly reduce the likelihood of a dendritic structure.

FIG. 20.

Long bar cast vertically, with gate, runner and riser.

FIG. 21.

Ingots for chemical analysis.

A T-shaped cross-section may have dendrites in two branches, but none in the third. If the movement or flow of molten metal continues until the temperature approaches the mushy stage, nuclei for crystal growth seem to appear throughout the entire mass, and both space and time for dendritic growth are lacking. If, however, this flow is continued until the temperature drops still further, there seems to be a tendency toward what may be called a variety of segregation. This condition is illustrated in Fig. 22. This figure represents a cross-section near the top of a long small casting poured with rather cold metal. A sketch of the pattern with method of gating is shown in Fig. 20. In pouring this casting the first metal to enter passed down 18 in. through the runner, then up 18 in. to the top. The small dark rounded areas of Fig. 22 are gas cavities similar in nature and cause to those seen in Fig. 10. The concentric arrangement of those constituents which are least attacked by the reagents seems to have been due to the flow continuing into the early part of the mushy stage.

The effect of movement of the molten metal as its temperature approaches the solidus upon the nature of the crystalline growth is well illustrated in Fig. 23. This figure is part of a section of a feeder about 2 in. in diameter. At the outside (top of figure) the normal radial dendrites are found; then there is an irregular zone of what, for a lack of a better name, may be called network structure; then a second zone of irregular dendrites, and in the center (bottom of figure) an area which seems to show segregation.

Figs. 24 and 25 are partial sections of chemical-test ingots which were cast in split iron molds. A sketch of one of these ingots is shown in Fig. 21. The walls of the small iron molds in which these are cast are about $\frac{1}{8}$ in. thick, and the metal solidifies very quickly. The ingot from which Fig. 24 was derived was cast with hot metal (carbon 0.20 per cent). The very small, needle-like dendrites should be compared with those in Fig. 16, which shows hot poured steel of similar composition but cast in a dry sand mold. The ingot represented by Fig. 25 was cast with 0.36 per cent carbon steel, temperature of casting unknown. The small grain size here should be compared with that seen in Fig. 17. The carbon content was different, and that may be partly responsible for the great difference in size of grains. The light areas at the bottom of both Figs. 24 and 25 were in the centers of the ingots. These

areas, like the one at the lower edge of Fig. 23, show what may be considered segregation, although the practical foundryman would attribute them to shrinkage. It is difficult to understand how there could have been sufficient time for segregation strictly as understood to take place in the chilled ingots.

MANY UNKNOWN CAUSES OF STRUCTURE

Many of the factors which influence the formation of dendrites are unknown. Two of the most important may be mentioned here as being well established by the data and also as being in line with theoretical considerations on this matter. The first is the relative

Fig. 23. Variable macrostructure in 2-in. feeder.

temperature of different parts of the molten mass during the solidification period, or, in other words, the thermal gradient. Dendrites grow from nuclei formed at or below the solidification point toward the hotter regions, as from the surface toward the center. Local heating or cooling conditions, such as the flow of metal through certain parts of the ingot, or the presence of a cavity, may cause a change in the direction of the

22

Fig. 22. Segregation in end of long casting.

24

Fig. 24. Hot steel cast in iron mold.

25

Fig. 25. Cold steel cast in iron mold.

dendrites. Again, if the metal when poured is near the solidification point, the conditions for dendritic growth may be lacking and the metal will solidify around nuclei well distributed throughout the mass, giving rise to the network structure. Second, selective freezing no doubt has a very important effect upon the macrostructure. This would account for the influence of phosphorus or of oxygen, if the theory of Le Chatelier and Bogitch be correct. But other elements besides these two have an influence upon selective freezing.

Our firm makes a very low-carbon cast steel which is used extensively for dynamo and motor frames because of its high magnetic permeability. This steel runs about 0.07 per cent carbon, 0.06 per cent silicon and 0.05 per cent manganese. Although cast at a very high temperature, an examination of a number of specimens shows that dendrites are of rare occurrence. The phosphorus content of this steel is as high as that of the higher carbon steel and there is every reason to believe that the oxygen content is at least as high. The absence of a well-developed macrostructure in this steel and its presence in the higher carbon steel cannot be accounted for by the theory that these two elements are the only controlling factors. Carbon, manganese and silicon may be considered to play an important part. So, too, alloy steels such as nickel and chromium show a highly dendritic structure.

CONCLUSION

In concluding this brief discussion of some miscellaneous studies of cast steel macrostructure, our previous statement may be repeated: The steel foundry offers exceptional opportunities and a fertile field to the research metallurgist. Most of the literature of the science of metallography, textbooks included, deals with forged or worked metal, and the technologist is still without accurate data on some very elementary matters. It is evident that a proper understanding of the crystalline structure of cast steel should begin with a study of its macrostructure.

Milwaukee, Wis.

Dyestuffs Trade in Japan

The following item appeared in the *Japan Chronicle* for June 4, 1920:

An official of the Mitsui Co. is quoted as stating that in Japan a small quantity of natural indigo was produced in Chugoku, Shikoku and Saitama Prefectures before the war, but the domestic demand for indigo was largely met by imports of the German indigotin. On the outbreak of the war the direct importation of German dyestuffs ceased, and prices rose in consequence, offering an opportunity for the establishment of dyestuff companies in Japan. The termination of hostilities, however, brought about a fall in price, and it is now considered that in view of the fact that Japanese dyes are inferior to foreign products in quality it is advisable to import the goods rather than to manufacture them at home. Even though Japan could produce dyestuffs equal in quality to those of foreign countries, it is unable to manufacture them at the same low cost.

Japan is able to manufacture black and methyl violet of good quality, and these manufactures not only supply the domestic demands but are exported to China in large quantities. Other kinds of dyes are, for the most part, imported from America, England, and Switzerland. The Miike factory of the Mitsui Co. is producing alizarine dyes.

The imports of dyestuffs into Japan for last year were valued at 15,000,000 yen (\$7,477,500 at normal exchange), while in pre-war days the imports were about 5,000,000 yen (\$2,492,500) worth of artificial indigo and about 5,000,000 yen (\$2,492,500) worth of

other kinds of dyestuffs. As the price was lower before the war, the quantity of imports was larger in pre-war years than last year. Before 1914, Germany and Switzerland were practically the only countries that produced artificial indigo, and most of the natural indigo was supplied by India and Java. The shortage during the war was very great, owing to the suspension of imports, and Japan was compelled to be economical with what it had left.

When the highest price was ruling, 200 yen (\$99.70) per kin (1.32 lb.) was a common price. At present the market has fallen to 15 or 16 yen (\$7.48-\$7.98) per kin. This decline in price is partly due to the economic depression now prevailing. Up to the end of February last the market price of 24 to 25 yen (\$11.96 to \$12.46) per kin had been maintained. "Direct" black had been quoted at 8.40 yen (\$4.19) per kin up to the end of February, but the price has fallen to 7 yen (\$3.49). It is even said that in some cases it is sold as low as 5 yen (\$2.49). At present there is no business, and although a good price will have to be paid by the buyer, there is practically no price that can be demanded by the seller. In short, the price has fallen by 20 per cent, being influenced by the present economic depression. The official of the Japanese firm quoted believes that the market price of dyestuffs will rise in the future, however.

Decline in the Production of Graphite

A heavy decline in the production of graphite in the United States in 1919 is shown by preliminary estimates just made public by the United States Geological Survey.

The shipments of domestic graphite amounted to approximately 7,717 short tons, valued at \$743,000, a decrease of about 41 per cent in quantity and 51 per cent in value from the figures for 1918. This decrease is apparently due to several well-known causes. After the War Industries Board, on Aug. 10, 1918, ordered the use of at least 25 per cent of American graphite in crucible mixtures to be sold during the year 1919, the purchases of domestic and Canadian graphite were heavy, reaching 500 tons or more a month during August, September and October, 1918. After the armistice was signed, however, on Nov. 11, 1918, an abrupt decline in shipments began, which was accelerated by the order of the War Trade Board of Jan. 16, 1919, removing all restrictions on purchases of graphite. This order naturally weakened the market, for customers were then already burdened by accumulated stocks. The cost of manual labor in the United States increased enormously in 1918 and 1919, but as the demand for graphite was weak and as the market was thrown open to foreign competition the producers were unable to raise their prices proportionately. Although marine freight rates had been increased, the producers of crystalline graphite in Ceylon and of flake graphite in Madagascar, by reason of cheap native labor and unusual conditions of foreign exchange, were able to market their product at prices that forced the smaller American producers to suspend production, so that at the close of the year 1919 only the strongest and best organized companies were able to continue operations.

DOMESTIC GRAPHITE SOLD IN 1915-1919
(Short Tons)

Year	Amorphous		Crystalline		Total	
	Quantity	Value	Quantity	Value	Quantity	Value
1915	1,181	\$12,358	3,537	\$417,273	4,718	\$429,631
1916	2,622	20,723	5,466	914,748	8,088	935,471
1917	8,301	73,481	5,292	1,094,398	13,593	1,167,879
1918	6,560	69,455	6,431	1,454,799	12,991	1,524,254
1919	4,000	47,000	3,717	696,000	7,717	743,000

During 1919 the New York prices for the best grades of Ceylon lump graphite ranged from 131 to 151 cents a pound. Domestic flake brought from 4 to 101 cents and dust from 1 to 3 cents.

Studies in Evaporator Design*—III

The Effect of Hydrostatic Head on Heat Transmission in Vertical Tube Evaporators — Method of Manipulation and Accuracy of Results — Maximum Heating One-Third Tube Depth†

BY W. L. BADGER AND P. W. SHEPARD

THIS paper reports a series of determinations of heat transmission in an experimental vertical tube evaporator, to show the effect of hydrostatic head (and incidentally the effect of the shape of the bottom of the evaporator) on this constant. This investigation was undertaken in the evaporator experiment station of the University of Michigan as a part of the general program of the study and correlation of all the factors and variables affecting heat transmission in evaporators. It was felt that since our general problem involved a quantitative study of evaporators on a larger scale, over wider ranges and with a different disposal of heating surface than any investigator has hitherto attempted as a research proposition, it would be well to risk the possible repetition of some of the work already done.

PRIOR LITERATURE

Claassen very early pointed out the fact that increasing the hydrostatic head on a surface must result in a decrease in heat transmission. He carried out some experiments in a small experimental evaporator which has been described in a previous paper.¹ His experiments on this subject are only four in number and the actual hydrostatic head is not recorded. The experiments with "high" hydrostatic heads show a heat transmission about 5 per cent lower than those with "low" hydrostatic heads.

Hausbrand² omits entirely the discussion of this point with reference to heat transmission.

Kerr³ has studied this point and has given several curves showing the effect of hydrostatic head on heat transmission. He shows that the maximum heat transmission occurs when the tubes are about one-third submerged, that the decrease in heat transmission at higher levels than this approximately follows a straight line and that this decrease is greater than the decrease calculated from the increased pressure. In other places in the literature⁴ are found the statements that vertical tube evaporators give the maximum heat transmission when the tubes are about one-third submerged.

APPARATUS

The experiments here described were run in the vertical tube evaporator at the evaporator experiment station of the University of Michigan. This apparatus has been previously described⁵. The steam basket employed in these runs contains twenty-four 2-in. 13-gage

charcoal iron tubes, 30 in. long. These experiments are divided into three series corresponding to different arrangements of the evaporator. In series A the body of the evaporator from bottom flange to top flange was 8 ft. high and the evaporator was equipped with a round bottom. In series B an intermediate section was added so that the body of the evaporator was 12 ft. high, but otherwise the same as in series A. Series C was also run with the body 12 ft. high, but a 60 deg. cone bottom was substituted for the round bottom of the previous tests.

METHOD OF MANIPULATION AND ACCURACY OF RESULTS

These have been discussed in a previous paper and this discussion need not be repeated here.

Results. The results are given in Tables I, II and III and in Fig. 1. At levels above 24 in., all the results at a point were averaged. At levels below 24 in., the results when the round bottom was used are averaged separately from the results with the cone bottom. In all runs the liquor level averaged less than $\frac{1}{2}$ in. from the desired point. Consequently all the individual results obtained at each level should be in a single vertical line. They are spread sideways a little to make it possible to distinguish individual determinations. There are several interesting features in this curve.

It will be noted that with the round bottom the maximum heat transmission occurs at exactly one-third submergence. This confirms the results of other investigators. It will also be noticed that at levels higher than the top tube sheet, heat transmission decreases with increase in level along a straight line; but this relation does not hold between the top tube sheet and the maximum.

The point of greatest significance is the difference in the shape of these curves, due to the shape of the bottom of the evaporator. The explanation for this difference is fairly obvious. As will be shown later, although these curves show the change in heat transmission as the liquor level is varied, this change is really due largely to changes in circulation and only to a small extent to changes in hydrostatic head. The round bottom contains a comparatively small amount of liquid in proportion to the amount above the bottom tube sheet and therefore circulation of the entire mass is very vigorous. The cone bottom contains a large mass of liquid which absorbs energy of circulation in eddy currents. With low liquor levels the proportion of liquid in the cone to liquid above the bottom tube sheet is large and therefore the effect of the cone is marked. As the liquor level rises the proportion of liquid in the cone becomes less, so that at levels approximately at the top tube sheet it has no effect on the general circulation.

The bearing of this relation on the design of evapo-

rators is obvious. A hopper bottom is used on a vertical tube evaporator when the formation of crystals or precipitates is expected. But under these circumstances it is comparatively rare that a vertical tube evaporator would be operated at low liquor levels because of the danger of building up deposits on the heating surface. When an evaporator is run as salting evaporators usually are, with the liquor level at the top tube sheet, the effect of the cone bottom disappears. On the other hand, in evaporators for liquids which can be boiled at low liquor levels it is of importance to keep the volume of liquid below the bottom tube sheet as small as possible.

CALCULATIONS

To determine how much of the effect shown by these curves is actually caused by hydrostatic head, points were read off the curves as plotted and recalculated to actual conductivities as follows:

Let t_g = temperature of heating steam (calculated from pressure).
 t_w = temperature of the boiling liquid at its surface (calculated from the vacuum).
 t_b = temperature of the boiling liquid at the bottom tube sheet.
 t_s = temperature of the boiling liquid at the top tube sheet.
 $\theta_1 = t_g - t_w$ = temperature difference at the surface (apparent temperature difference).
 $\theta_2 = t_g - t_b$ = temperature difference at the bottom tube sheet, corrected for hydrostatic head.
 $\theta_3 = t_g - t_s$ = temperature difference at the top tube sheet, corrected for hydrostatic head.
 θ_{mh} = mean weighted temperature difference, corrected for hydrostatic head.
 p_g = absolute pressure in the vapor in mm. mercury.
 p_b = head of liquid on the bottom tube sheet, mm. mercury.
 p'_b = head of liquid on the top tube sheet, mm. mercury.
 $p_b = p_g + p_b$ = total pressure at the bottom tube sheet in mm. mercury.
 $p_t = p_g + p'_b$ = total pressure at the top tube sheet, mm. mercury.
 H_g = heating surface above liquor level, sq.m.
 H_b = heating surface below liquor level, sq.m.

Then to illustrate the derivation of the values in Table II, for hydrostatic heads below the tube sheet, the following computation is given:

$$\begin{aligned} p_g &= p_v = 283.9. \\ p_b &= p_g + p'_b = 283.9 + 43.6 = 327.6. \\ t_g &= t_w = 74.57. \\ t_b &= 78.05. \\ \theta_1 &= \theta_2 = t_g - t_w = 100.11 - 74.57 = 25.54 \text{ deg.} \\ \theta_3 &= t_g - t_s = 100.11 - 78.05 = 22.06 \text{ deg.} \\ \theta_{mh} &= \frac{\theta_2 H_b}{H_g} + \frac{\theta_1 H_g}{H_b} = \frac{(22.06 \times 3.191) + (25.54 \times 0.882)}{4.073} = 24.12 \text{ deg.} \end{aligned}$$

$$\text{Then the corrected } K = \frac{\theta_1}{\theta_{mh}} (\text{apparent } K) = \left(\frac{25.54}{24.12} \right) 2167 = 2293.$$

For levels above the top tube sheet the calculation differs. The corrected temperature at the top tube sheet must be computed, and the arithmetical mean between this and the corrected temperature drop at the bottom tube sheet becomes the new mean (θ_{mh}) from which the corrected K is calculated. The following calculation is for a level 72 in. above the bottom tube sheet:

$$\begin{aligned} p_t &= p_g + p'_b = 283.9 + 76.5 = 360.4. \\ p_b &= p_g + p_b = 283.9 + 131.1 = 415.0. \\ \text{From steam tables} \\ t_g &= 80.38. \\ t_b &= 83.91. \\ \theta_2 &= t_g - t_b = 100.11 - 80.38 = 19.73. \\ \theta_3 &= t_g - t_s = 100.11 - 83.91 = 16.20. \\ \theta_{mh} &= \frac{\theta_2 + \theta_3}{2} = 17.96. \end{aligned}$$

$$\text{Corrected } K = \frac{\theta_1}{\theta_{mh}} (\text{apparent } K) = \left(\frac{25.54}{17.96} \right) 1248 = 1776.$$

In taking θ_{mh} as the arithmetical mean the assumption has been made, to simplify calculation, that the boiling point of water is a linear function of the hydro-

static head. This is, of course, not so, but for want of a simple equation expressing the relationship the above approximation is taken as true enough for our purpose.

The results are connected by the curve indicated in Fig. 1. Evidently the effect of hydrostatic head is subordinate to the effect of velocity of circulation. More detailed discussion of the effect of velocity is unprofitable until a considerable number of similar curves under different conditions of operation have been determined.

It should be emphasized that the elevation in boiling point, due to increased hydrostatic head, is not shown by a thermometer immersed in the lower part of the boiling liquid. In an evaporator of the type here used, where the descending circulation is in the outer annular down-take space, a thermometer inserted into this annular space should always read a temperature corre-

FIG. 1. VARIATION OF HEAT TRANSMISSION WITH HEAD

sponding to the vacuum or a little lower. The liquid in this down-take space is coming from the upper part of the evaporator, where it has lost any superheat it may have had, and must enter the down-take either at the temperature corresponding to the vacuum or at a lower temperature if it cools by radiation.

If the columns showing temperature calculated from vacuum and temperature of body are compared it will be seen that the temperature read by the thermometer tends to be lower than that calculated from the vacuum at low liquor levels and higher than that calculated from vacuum at high liquor levels. This thermometer

was situated not far from the feed inlet and consequently at low liquor levels (which mean high rates of evaporation and consequently high rates of feed in proportion to the total amount of liquid in the evaporator); it gives a low reading, due to currents of colder feed liquor. Through the middle of the range, where the effect of feed is less and yet circulation is strong, the two temperatures agree fairly well. At very high temperature levels there is very little real circulation, but rather an agitation or bouncing. This bouncing may at times result in some superheated liquid from the lower part of the steam basket being carried up into the annular space as far as the thermometer bulb. At ordinary levels and with ordinary circulation there will be no appreciable elevation of the general temperature of the boiling liquid.

CONCLUSIONS

The following conclusions must be for the present considered as indicating tendencies only, and should be applied with caution to evaporators which differ very much in design from the evaporator in which they were determined.

1. The maximum heat transmission when boiling water or other non-foaming, non-viscous materials in

a vertical tube evaporator occurs when the tubes are from one-third to one-half submerged.

2. The position of this maximum point and its value depends on the size and shape of the evaporator bottom. With bottoms containing little liquid below the bottom tube sheet the maximum occurs at lower levels and has a higher value than with bottoms containing large amounts of liquid.

3. Differences in the shape of the bottom have little effect on heat transmission when the amount of liquid in the evaporator above the bottom tube sheet is larger than the amount of liquid below the bottom tube sheet.

4. As the liquor level is increased above the top tube sheet the heat transmission falls off along a straight line.

5. The change in heat transmission with changing liquor level is only partially due to the effect of hydrostatic head. Changes in velocity of circulation are a very important factor.

All the work of this paper was done with funds supplied by the Swenson Evaporator Co., to which the authors wish to express their indebtedness for permission to publish these results.

Step-Induction Regulator for Electric Furnace Voltage Control

FOR controlling the energy input for carborundum, graphite, aluminum, zinc and similar types of electric furnaces, the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., is manufacturing a step-induction regulator which gives a uniform voltage over a wide range. The regulator consists of a furnace transformer, an induction regulator, switches and push-button control. This apparatus utilizes the principle of varying the high-voltage tap on the transformer for controlling the energy input to the furnace.

The function of the induction regulator is to vary the voltage between taps. After the voltage of the adjacent tap is reached the selector and transfer switches automatically transfer the induction regulator so that it will function between the next two taps. One of the main features of this apparatus is that the entire voltage range is controlled by two push-buttons, one for boosting and one for bucking the voltage.

The construction of the apparatus is as follows: On the shaft of the regulator is geared a selector switch, the joints on this switch being connected directly to taps on the high voltage winding of the furnace transformer. The selector switch-arm moves from one contact to the next automatically as the induction regulator moves. The function of the feeder voltage regulator is to add to or subtract from the normal voltage of a transformer tap and is designed so that at the position of maximum boost it will add exactly one-half of the voltage between adjacent transformer taps, while at position of maximum buck it will subtract exactly one-half the voltage between adjacent transformer taps. Considering, then, a single position of the selector switch-arm, a single rotation of the moving coil of the induction regulator will vary the voltage impressed on the high tension winding from a position one-half step below to a position one-half step above the voltage point actually represented by the transformer tap. The selec-

tor switch arm is moved from one tap to the next just as the voltage one-half way between adjacent taps is reached, so that continued rotation of the regulator coil produces a continuous variation, raising or lowering the voltage depending only on the direction in which the regulator coil is being turned.

While the above is the fundamental operation of the apparatus, in actual practice there are slight modifications. The moving coil of the regulator makes but one-half revolution to go from the position of maximum

FIG. 1.
Step-induction regulator complete with transformer and control panel, 1,100 kva., 14,500 volts, single-phase, 25 cycle, low-voltage range, 40 to 50 volts.

buck to the position of maximum boost, at which latter point the selector switch moves to the next higher voltage tap, and the regulator must be brought at this point to maximum buck before it can, by continued operation, raise the voltage over another step. That is, at this point, the direction of current through the regulator coil must be reversed. Actually, the result is

obtained by a second coil of opposite polarity which is cut in at the proper time by a transfer switch and the regulator changes directly from maximum boost to maximum buck, so that continued rotation still acts to raise the voltage. The two-coil arrangement also makes desirable two-selector switches geared together for continued voltage variation. With high incoming line voltage a series transformer is interposed between the high tension line and the induction regulator. This allows the use of a less bulky low voltage induction regulator, and insures against trouble with insulating moving parts for high potentials. In this case, two coils are incorporated with the series transformer instead of in the regulator itself, and accomplish the same current reversing purposes. The operation of this regulator may be seen by reference to the schematic diagram.

Assume that the circuit is complete from the incoming high voltage positive line through one-half the high tension winding of the power transformer, through transfer switch *T* contact *a* to the upper coil of series transformer *SR* and through selector switch *S* to tap 1 on the other half of the high-tension winding, which is divided into equal voltage sections. The primary of the series transformer connects directly to the secondary or

FIG. 2. DIAGRAM OF CONNECTIONS

moving element of the induction regulator *R*. The series transformer then serves only to insulate the induction regulator from high line voltage, any voltage variation due to induction regulator movement being reflected proportionately in the series transformer coil which is in series with the main supply line. The induction regulator, therefore, adds to or subtracts from normal line voltage in the same manner as though the series transformer were omitted. Assume that the induction regulator is in such position that no voltage is induced in its rotating element. Voltage then is neither added nor subtracted by the series transformer coil and line voltage is impressed across thirteen-fourteenths (one-half plus six-fourteenths) of the high-tension winding and the low-tension voltage will be fourteen-thirteenths of what it would be with the voltage impressed across the entire winding.

Turn the rotating element of the induction regulator from the neutral, and voltage will be induced in its secondary coil from the primary winding which is constantly excited from an auxiliary coil *A* on the power transformer. The induction regulator and series transformer combination is designed so that its maximum

voltage is equal to one-half the voltage difference between adjacent taps. Assume that the moving element is rotated so that the induced voltage adds to that of the line; evidently depending upon the amount of rotation from the neutral no-voltage position the effective voltage of the line may be raised from the normal voltage of tap 1 to any point up to a maximum corresponding to a voltage one-half way to tap 2. With coil rotation in the opposite direction, the induced voltage will subtract from the line, and continued movement of the coil will lower impressed voltage to a point corresponding to that one-half way to tap 0 on the transformer winding. In other words, the range of the induction regulator and series transformer combination itself is between adjacent transformer taps.

Consider now that the induction regulator has been rotated to its maximum boost position, while connected to tap 1. In effect a voltage one-half way between tap 1 and 2 is impressed upon the power transformer winding. Evidently the same result in voltage would be obtained if the coil of the series transformer were connected to tap 2 and the induction regulator was in its maximum buck position. With the coil voltage bucking, continued rotation in a boost direction would raise the voltage through the range of the induction regulator and progress over another step could be undertaken.

It is desirable, therefore, at the position of maximum boost to advance connections to the next higher voltage tap and simultaneously to change the induction regulator to give maximum voltage buck. This is accomplished by driving selector switch *S* and transfer switch *T* through gearing from the induction regulator shaft so that taps on the transformer winding are connected automatically and at the proper time polarity is changed from maximum voltage boost to maximum voltage buck. Continued rotation in one direction of the induction regulator raises the voltage over the entire range.

Any voltage within the range of the extreme taps on the transformer winding may be obtained by closing a two-way switch in either a "raise" or "lower" position, the voltage setting of the regulator being indicated by an adjacent voltmeter.

Difficulties of the German Paper Industry

According to a recent issue of *Kölnischer Zeitung*, the German paper industry is seriously handicapped by the scarcity and increased prices of raw materials. This is particularly true of old paper and rags, which are extremely difficult to obtain and have reached a price which appears unjustified. It is believed that old paper and rag dealers have been holding their supplies to drive prices up. The demand is very great and constantly increasing in spite of the fact that consumers believe present prices cannot continue. The cellulose plants in eastern Germany, which have been forced to suspend production for some weeks owing to the shortage of coal, have recently resumed operations, and it is hoped that renewed deliveries of cellulose will help to drive down the prices of old paper and rags. Straw, which is used in large quantities in the German paper industry, is now quoted at 55 to 60 marks per 100 kilos, but this price is expected to fall in the near future. It is hoped that this will also have an effect on the prices of other raw materials. Wages in the industry have risen over 100 per cent since December, and the cost of coal, chemicals, dyes and other raw materials has risen in like manner.

Synopsis of Recent Chemical & Metallurgical Literature

Synthetic Ammonia.—GEORGES CLAUDE has recently outlined the results of his work on synthetic ammonia before the Société Chimique de France and the Société d'Encouragement pour l'Industrie Nationale de France. He proposes the use of ammonium chloride instead of ammonium sulphate as fertilizer and stated that in the manufacture of the chloride for each kg. of fixed nitrogen produced it will be possible to obtain with practically no additional cost more than three tons of sodium carbonate. He reviews the history of the production of synthetic ammonia by the use of catalyzers and high pressures, and cites that the French chemist Tellier as late as 1867 was the first to make use of the affinity of iron for nitrogen. A few years later iron at red heat was used as catalyzer for the production of synthetic ammonia, but with little practical results.

It was due to the work of the German chemists Nernst and Haber based on the theoretical principles of the Frenchman Le Chatelier that synthetic ammonia can be produced now industrially and on a commercial scale. Nernst used iron as catalyzer with a 50 to 75 atm. pressure with encouraging but not economic results. Haber, with the financial help of the Badische Anilin, studied the catalyzing properties of uranium and osmium and succeeded in replacing iron as catalyzer by what the Badische Anilin calls activators. By the use of high pressures (200 atm.) and specially constructed machines it was possible for the Badische Anilin Co. in 1912 to realize large-scale production of synthetic ammonia, with its activators at red heat, and hydrogen from water gas at its Oppau plant.

Mr. Claude, studying further Le Chatelier's axiom that ammonia is formed with reduction of volume and that this formation is greatly facilitated by pressure, succeeded as late as 1917 in realizing his hyper-compressors for the production of 1,000 atm. pressure which now can compress 100 cu.m. of the mixture $N_2 + 3H_2$ per hour. The working of the apparatus is so simple that he was able to have a model in operation before his audience. He dwelt on the advantages in using hyper-pressures.

With the pressures used in Germany (200 atm.) the efficiency is 13 per cent, whereas with the pressure used by Claude the efficiency is 40 per cent. In both cases the use of a catalyzer is indispensable, and the temperature used is quite the same.

For a capacity of 100 cu.m. per hour per liter of catalyzing space the percentage of NH_3 can reach 25 per cent with the Claude process, as against 6 per cent with the Haber process, figures which correspond to a production of 6 g. instead of 0.5 g. per hour per gram of catalyzer.

In the German process the efficient combination of the gases takes place only by their passing a great number of times over the catalyzer and by the elimination of the NH_3 , formed with water injected under pressure, whereas in the Claude process the gases once compressed are passed successively through three or four apparatuses in series and the pressure of the

ammonia formed is still so high (250 atm. instead of the 12 atm. with the Haber process) that it is liquefied by its merely passing through a coil immersed in water.

Another advantage of the Claude process is that the product is liquefied NH_3 , instead of an aqueous solution (Haber) from which the NH_3 has often to be recovered by distillation.

In the Haber process operating difficulties arise from the fact that the temperature must be increased by costly means. With the Claude process this is just the reverse, as the heat of reaction is even higher than that required and has often to be lowered. Under the operating conditions for synthetic ammonia it is certainly easier and more economical to lower the temperature than to raise it.

In the Haber process the production of the highly purified hydrogen requires enormous installations, whereas with the Claude process the hydrogen may be obtained by electrolysis of water or as a byproduct from coke-oven gas. This is a very important economic problem when it is considered that in the nitrogen fixation industry 1 part nitrogen requires 3 parts hydrogen. Mr. Claude is experimenting on a method by which to extract hydrogen from any hydrogen-containing gas mixture. If his expectations from this method are justified, as he thinks they are, it will be possible to install synthetic ammonia plants near coke ovens where at present immense quantities of hydrogen-containing gases are actually lost or badly utilized.

The advantages of the Claude process outlined above and other additional mechanical advantages and installation facilities warrant the statement that the Claude process is at present the most efficient and economical means of producing synthetic ammonia. The ease with which the process has been practically demonstrated before the audience is the best proof of its practicability. (*L'Industrie Chimique*, July, 1920.)

The Properties of Stoneware Clays.—Results of experiments conducted by the Bureau of Mines at its ceramic station at Columbus, Ohio, on the properties of some Ohio and Pennsylvania stoneware clays are described in Technical Paper 233, recently issued by the bureau, entitled "The Properties of Some Stoneware Clays," by H. G. SCHURECHT. The work has special reference to the possible use of these clays in making chemical stoneware, but many of the results brought out can be applied to other industries as well. It was conducted in co-operation with the Ohio Geological Survey, the Pennsylvania Geological Survey also assisting in collection of samples.

The resistance of vitrified clay to chemical action, together with its impenetrability to liquids, has made chemical stoneware an important product in the chemical industries. Stoneware distilling kettles, receivers, filters, condensing worms, centrifugal pumps, acid-proof pipe fittings, tower packing, acid-proof tanks, photographic tanks, and troughs and tubes for electrical processes are used in these industries. Stoneware equipment is also used in the preparation of foods, as, for example, sugar, flavoring extracts, and preserves. During the war, on account of the increased production of explosives and the production of poisonous gases, there was a marked increase in the demand for chemical stoneware and stoneware clays. A wider use of chemical stoneware is limited only by its comparative brittleness and sensitiveness to sudden temperature changes.

From each of the eleven clays tested, a series of seven bodies was prepared, the clay being ground to different grades of fineness and used alone and with varying proportions of feldspar, or feldspar and calcium carbonate added. From these bodies test pieces were prepared for which the drying shrinkage, tempering water, shrinkage water, pore water, rate of slaking in water, and transverse strengths in the green condition were determined for each body. The softening temperature and the porosity and volume shrinkage at various temperatures were determined by firing tests.

The results are tabulated in detail, and show a wide range of properties among the different clays tested. They indicate that some of the clays might be used for chemical stoneware.

Aluminum as Catalyst in the Preparation of Chlorobenzenes.—Chlorine combines directly with benzene under the influence of sunlight producing the α and β benzene-hexachlorides, but in the dark chlorination takes place only in the presence of a catalytic agent. The first catalyzer used was iodine, but JEAN MEUNIER has found that the catalytic action of aluminum is far superior to that of iodine and he presented the results of his work at the June 14, 1920, meeting of the French Academy of Sciences (*Comptes rendus*, vol. 170, No. 24, pp. 1451-2). He found that the best conditions for the preparation of chlorobenzenes, especially of the monochlorobenzene, is to use aluminum filings in the proportion of 1 part aluminum for 1,000 parts of benzene. During the chlorination the products obtained are C_6H_5Cl plus some more chlorinated benzene. When it is desired to produce only the monochlorobenzene it is necessary to stop the supply of chlorine when the density of the liquid reaches 1.008 at 15 deg. C., the density of the benzene being 0.876. The fractionation of this liquid made under reduced pressure and by heating on a water bath gives the following results:

	Per Cent
C_6H_5Cl (density 1.1084 at 11 deg. C.).....	77
Light products (benzene and traces of C_6H_5Cl).....	13
Denser products (dichlorobenzenes).....	10

The light products are submitted to additional chlorination, giving 10 per cent C_6H_5Cl . The total efficiency of the process is thus 87 per cent.

Determination of Zirconium and Titanium in Zirconium Ores.—An article on "The Determination of Zirconium and Titanium in Zirconium Ores," by G. E. F. LUNDELL and H. B. KNOWLES, appeared in the July, 1920, number of the *Journal of the American Chemical Society*, pages 1,439-1,448. This article may be summarized as follows: Methods of decomposing zirconium ores are listed. A cupferron method for the determination of zirconium and titanium in zirconium ores is given. The method provides for the following elements which have been found in zirconium ores: Zirconium, titanium, silicon, thorium, cerium, iron, aluminum, scandium, yttrium, erbium, didymium, glucinum, calcium, magnesium, sodium, potassium, lithium, uranium, phosphorus, tantalum, manganese, zinc, cobalt, tin, lead, copper, and bismuth. It is also worthy of note that chromium and nickel do not interfere in a cupferron precipitation; that tungsten would not cause trouble since it is removed before the final precipitation; and that vanadium would require special treatment. Since this element has not been reported in zirconium ores, and since its presence in significant amounts would be indicated at various stages of the analysis, it would cause no trouble.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Manufacture of Bromates.—In the manufacture of bromides, solutions containing sodium bromide and sodium bromate are obtained. The best fractional crystallization of this mixture leaves a liquor containing the salts in the ratio of about 93 per cent NaBr to 7 per cent $NaBrO_3$. In order to effect a complete separation, COULTER W. JONES, of Midland, Mich., takes advantage of the relative insolubility of barium bromate, which is precipitated from the mixture by adding barium bromide:

The alkali bromate may be reformed by treatment with alkali carbonate:

The barium carbonate is converted into bromide for use in the first step by hydrobromic acid or ferric bromide. (1,343,918; assigned to Dow Chemical Co.; June 22, 1920.)

Sodium Sulphite.—Calcium sulphite, which is a waste product in the manufacture of certain spray compounds and in the manufacture of magnesium chloride by certain processes, may be converted into sodium bisulphite by treatment with sodium bisulphate or niter cake:

Milk of lime changes the acid sulphite into normal sulphite according to the equation:

Magnesium Arsenate.—Certain compounds of magnesium with arsenic acid are entirely suitable for insecticidal use and, according to EDWIN O. BARSTOW, of Midland, Mich., possess certain physical characteristics which render them equal to if not superior to lead arsenate and calcium arsenate. The preferred compounds, $MgHAsO_4$ and $Mg_3(AsO_4)_2$, may be prepared from magnesium hydroxide and arsenic acid or from magnesium chloride and sodium arsenate. (1,344,018, assigned to Dow Chemical Co.; June 22, 1920.)

Aluminum Nitride.—Briquets of finely-ground alumina and the calculated quantity of carbon are mixed with larger pieces of carbon in the form of coke, etc., and fed continuously through an electric furnace provided with stationary electrodes and an inlet for gas containing nitrogen, such as producer gas. The larger carbon pieces serve as resistors and carry most of the current required to heat the mass to the reaction temperature, at the same time separating the briquets and preventing them from fusing together. Owing to difference in size, the discharged mixture of briquets and resistors can easily be separated by screening. The resistors are used repeatedly until reduced in size by mechanical wear to a point where separation from the briquets becomes difficult. (1,344,153; MARK SHOELD, of Chicago, Ill., assignor to Armour Fertilizer Works; June 22, 1920.)

Electrolytic Oxygen-Hydrogen Generator.—Certain improvements in unit type oxygen-hydrogen generators are embodied in a cell designed by EDWARD O. BENJAMIN, of Newark, N. J. The diaphragm and all electrode surface exposed within the cell are completely submerged in the electrolyte, thus insuring the efficient functioning of these parts. There is no non-generating electrode surface to waste energy by reversing and acting as a gas battery. An additional advantage of such construction is its adaptability for use on shipboard. Since circulation of electrolyte through the diaphragm tends to impair its gas-proof qualities, provision is made for circulation of the electrolyte (due to difference in specific gravity of the electrolyte on opposite sides of the diaphragm) through suitable passages in the frame above and below the diaphragm. The circulation is slow and the passages are so constructed that there is no possibility of entrained gases passing from one side of the diaphragm to the other. Any number of cells may be connected in series by bolting together the side extensions on the plate electrodes. Should trouble develop, the cell or cells responsible may easily be short-circuited, disconnected and removed for repair without interfering with the operation of the remaining cells. (1,344,220; assigned to International Oxygen Co.; June 22, 1920.)

Synthetic Tanning Material.—Sulpho-phenol carboxylic acids and sulpho-cresol-carboxylic acids will yield condensation products with formaldehyde which are amorphous and water-soluble and which will produce a white, soft and strong leather when employed as tanning materials. (1,344,950 and 1,344,951; ARTHUR KOETZLE, of New York, N. Y., assignor to Rohm & Hass Co.; June 29, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Ammonium Sulphate.—Dry neutral ammonium sulphate is manufactured by treating the commercial salt with a neutralizing agent and simultaneously to agitation and drying under the action of heat, a granular or pulverulent product being obtained if the material is also subjected to treatment to effect mechanical reduction, while if the treatment is effected under suitable conditions, for instance in a partial vacuum or in a gas current, the pyridine is removed and can be recovered. The neutralizing agents mentioned are lime, magnesia or other alkaline earths or their carbonates, alkalis or their carbonates, ammonia, or suitable ammonium salts such as the carbonate, sulphide or sulphite. They may be added dry or as solutions or suspensions, and ammonia may be used in the form of gases, such as coal-gas, containing it, which, if hot, may effect the drying. The apparatus employed may contain grinding bodies, such as balls or pebbles. The gases escaping from the apparatus may be treated for instance with an absorbent such as water, acid solution or an oil or may be submitted to condensation, in order to recover pyridine and any escaping ammonia. In an example, the ammonium sulphate is treated with a small quantity of lime or of ammonia liquor in an externally heated ball-mill. Air is then blown or sucked through, the escaping gas being washed in a scrubber supplied with acid solution of ammonium sulphate such as a saturator mother-liquor. When a product is desired free from pyridine, the quantity of the neutralizing-agent should be equivalent to

the quantity of the free acid plus the acid combined with the pyridine. (Br. Pat. 141,787—1919. S. E. LEOD-HOLT, Buckhurst Hill, Essex, and R. LESSING, London, June 23, 1920.)

Ammonium Sulphate.—Dry and neutral ammonium sulphate is prepared from the sulphate obtained by passing ammonia into sulphuric acid, by neutralizing in known manner the crystals separated in an acid condition from the liquor, and then drying them at a raised temperature, for example by causing the crystals to descend a tower up which heated air is passed. The dry and neutralized sulphate so obtained may be afterwards crushed. (Br. Pat. 141,798—1919. SOUTH METROPOLITAN GAS CO., E. V. EVANS and H. HOLLINGS, London, June 23, 1920.)

Production of Oxides of Tin and Zinc.—Oxides of tin and zinc are produced by supplying a blast of air under high pressure, say 4 or 5 lb., into the melted metal, and a blast of air under low pressure, say 0.15 to 0.5 lb., above the surface of the metal, auxiliary heating by an oil burner being employed if necessary. The oxide

is carried off by the blast and collected.

The apparatus consists of a tilting furnace *a* on trunnions *b*, Fig. 1, or rollers *g*', Fig. 3, having an oil burner *c*, a low-pressure blast *d* or *d'*, and a high-pressure blast *e*, which may be provided with a rod *e'* to keep the opening clear. In the arrangement shown in Fig. 1, the furnace is heated and charged while horizontal, and is then tilted as shown in dotted lines to bring the open end *a'* opposite the low-pressure blast *d* and submerge the high-pressure blast.

In the arrangement shown in Figs. 2 and 3, two high-pressure blasts *e'* are provided at opposite sides, the

furnace being tilted so that first one and then the other is submerged. A screen *a'* is arranged below the burner *c*, and a baffle *a''* directs the flame downward. Ingots *a''* of metal are fed in beneath the screen *a'* without allowing the fumes to escape. In an arrangement of this kind, the low-pressure pipe *d'* may be dispensed with, the opening *a'* then being plugged, and the low-pressure blast is sent in through the burner *c*. The temperature can then be controlled by regulating the proportions of air and oil admitted through the burner. (Br. Pat. 142,157—1919. H. MACONCHIE, London, and D. DE ROS, Greenhithe, Kent, June 30, 1920.)

Recovery of Nickel Oxide From Alloy or Scrap.—Copper-nickel alloys or metallic scrap are treated for the recovery of nickel oxide by melting in a basic reverberatory furnace or in a basic converter, and air is blown on to the surface or through the molten mass. Nickel oxide volatilizes and is recovered, for instance, in a bag-house or by electric precipitation. (Br. Pat. 142,310—1919. A. MCKECHNIE and MCKECHNIE BROS., London, June 30, 1920.)

Fatty Acids; Soaps.—Fatty acids containing a number of double linkages are converted into fatty acids resembling oleic acid by saponifying them for their glycerides, and heating the resulting neutral soaps to 210-250 deg. C. without evaporation to dryness. The product may be treated with mineral acid to isolate the fatty acid, or may be used as soaps if alkalis are used as saponifying agents. If alkaline earths are used for saponification, the products may be treated with alkali carbonates for the production of soaps. As raw material, sesame or cottonseed oil or the fatty acids therefrom may be employed. (Br. Pat. 141,720—1919. PERSAPOL GAS, Hanover, Germany, June 19, 1920.)

Hydrogen Peroxide.—An alkaline persulphate, e.g. ammonium persulphate produced electrolytically, is separated from the greater part of the electrolyte by means of a vacuum or centrifugal filter, and is placed in a steam-jacketed horizontal tube into which steam is introduced and which is connected through the medium of a condenser to a vacuum pump. The hydrogen peroxide produced collects in the condenser, and the residue of alkali bisulphate remaining in the tube, after dissolving in a quantity of water, can be returned to the electrolytic chamber, since the ratio of base to sulphuric acid has not been changed. (Br. Pat. 141,758—1919. L'AIR LIQUIDE SOC. ANON. POUR L'ETUDE ET L'EXPLOITATION DES PROCÉDÉS G. CLAUDE, Paris, France, June 16, 1920.)

Ammonium Sulphate.—The acid usually present in ammonium sulphate is removed by washing the sulphate at a raised temperature with a solution of ammonia obtained by condensing the vapors from a fixed ammonia still and diluting the solution thus obtained to such a strength that, at the temperature at which it is to be used, the vapor pressure of the ammonia is too low to entail substantial loss of ammonia. By washing at a raised temperature, chilling of the ammonium sulphate crystals, which might lead to the choking of the centrifugal, is avoided. A suitable diluent for the ammonia solution is obtained by subjecting the hot waste liquor from the fixed ammonia still to a slightly reduced pressure, and condensing at a suitable temperature the mixture of steam and ammonia withdrawn. (Br. Pat. 141,819—1919. SOUTH METROPOLITAN GAS CO., London, P. PARRISH, London, W. A. M. VALON, Stafford, June 23, 1920.)

Plastic Compositions.—A plastic composition which is a non-conductor of heat and electricity and is incombustible, is formed by mixing fibers of paper, wood, rag, etc., plaster, and a solution of gelatine containing stannic oxide. The mixture is heated with a solution of formaldehyde or of sodium bichromate. Colors may be added. An example of proportions is 25 parts of fiber, 175 parts of plaster, 45 parts of gelatine, 10 parts of tin dioxide and 110 parts of water mixed with 5 parts of formalin or sodium bichromate in 30 parts of water. (Br. Pat. 141,987—1919. L. DELEGLISE, Boulogne sur Mer, June 23, 1920.)

Basic Magnesium Hypochlorite.—When chlorine is passed into an aqueous suspension of magnesium oxide, basic magnesium hypochlorite is precipitated, provided that for every molecule of normal hypochlorite produced, more than two (preferably five to six) molecules of magnesia remain unattacked. The most favorable temperature for the process is 20-22 deg. C. Practically the whole of the available chlorine is absorbed by the pre-

cipitate without any appreciable production of chlorate if, after the introduction of the chlorine, the reacting mixture be allowed to stand for a considerable time, or be heated to 80 deg. C. and kept at that temperature for from 6 to 8 hr. in the dark. The precipitate, after washing well with hot water, is dried with exclusion of carbon dioxide. (Br. Pat. 142,081—1919. G. KERESZTY and E. WOLF, Budapest, Hungary, June 23, 1920.)

Vulcanizing India Rubber.—In the vulcanization of rubber compounds by hot air, litharge or its derivatives are replaced by an organic or inorganic reducing agent to obtain a light-colored product. Suitable reducing agents are hydroquinone, pyrogallol, tannins, paramidophenol, glycerine, trioxymethylene and other derivatives of formaldehyde, hydrosulphites, neutral sulphites. In general, the amount of reducing agent should not exceed 10 per cent of the rubber. (Br. Pat. 142,083—1919. A. H. HELBRONNER, Paris, June 23, 1920.)

Cracking of Hydrocarbons.—In the cracking of hydrocarbon oils, the thermal decomposition of fats to obtain glycerine, the production of oil and coal gas, and the destructive distillation of coal, peat, shale, etc., the lower molecular weight products are separated, while the higher molecular weight products and undecomposed substances are retained for further exposure to the decomposition conditions, by interposing one or more porous septa between the decomposition chamber and the condenser or receiver. The decomposition conditions may be maintained up to the porous septum; but it is preferred to place the porous septum in a separate chamber inside or outside the decomposition vessel; and a plurality of diffusion chambers may be used arranged either in series or in parallel. The invention is applicable to processes carried out either in the vapor or liquid phases; and in the former case, the removal of the vapors is facilitated and controlled by lowering the pressure on the condenser side of the septum with respect to that on the other side. (Br. Pat. 142,206—1919. W. MANN, London, June 30, 1920.)

Alkali Cyanides.—Alkali cyanides are obtained by reacting upon carbon and nitrogen with an alkali metal and an alkali metal compound. The alkali metal, such as sodium, may be used in the form of vapor, which may be mixed with carbon monoxide, and may be used to suck in the powdered alkali metal compound, such as soda. The alkali metal compound may be used in powdered or liquid condition, and may be introduced with the charge of carbon. (Br. Pat. 142,122—1919. H. MEHNER, Berlin, June 30, 1920.)

Hardening and Tempering.—Relates to means for hardening and tempering a nickel-chromium steel armor-piercing projectile having zones of steel of successively increasing hardness toward the point. The projectile, which is made of steel containing 0.58 to 0.7 per cent of carbon, 2 to 3.5 per cent of nickel and 2 to 3 per cent of chromium, is heated all over to 800-860 deg. C. and dipped point downward to its base in water until properly hardened, when it is removed and tempered by heating to a base temperature of about 760 deg. C. and an internal temperature of about 575-700 deg. C., while the head is immersed to a small depth in water; it is then cooled in the tempering plant to an internal temperature of 320-120 deg. C., after which it is cooled to atmospheric temperature. (Br. Pat. 142,148—1919. Sir R. A. HADFIELD, Westminster; A. G. M. JACK, Sheffield, and I. B. MILNE, Totley, Derbyshire, June 30, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Chemical Warfare Officers' Reserve Corps

Second in importance only to the establishment of the Chemical Warfare Service as a separate entity within the War Department was the order of the Secretary of War dated Aug. 24, 1920, authorizing the immediate formation of a Chemical Warfare Officers' Reserve Corps. General Amos A. Fries, Chief of the Chemical Warfare Service, announces that he will begin the formation of the Reserve Corps at once. He hopes to be able to obtain the assistance of some of the officers who will enter the Reserve Corps to assist in the organization work.

"This Reserve Corps means," said General Fries, "that the Chemical Warfare Service will know where to put its hand on two thousand chemical warfare officers in case of an emergency. Each member of the Reserve Corps will be classified carefully as to his specialties and other qualifications. This will permit their being called into service only as needed.

"The Reserve Corps not only will put the Chemical Warfare Service in a position to render most efficient work, but it will provide a highly necessary step in the interest of the national defense."

The fact that reserve officers may not be called into service in peace time without their consent and the fact that the Chemical Warfare Service is a separate subdivision of the War Department remove the principal objections to membership in the corps. During the time the placing of the Chemical Warfare Service in the Quartermaster Corps was being considered, many former chemical officers objected to entering the Reserve Corps, since there was no assurance that they would not be detailed to any duties in the Quartermaster Corps.

It is the hope of General Fries that he will be able to draw officers from the Reserve Corps for short periods of duty. He believes that many chemists would be willing to spend their vacation periods on duties pertaining to the work of the service. During such temporary duty the reserve officers would receive the pay of their rank and would be given mileage.

Chemists Perfect Process of Protecting Raw Sugar From Mold and Bacteria

According to a bulletin of the Louisiana Sugar Experiment Station in New Orleans, Dr. Nicholas Kopeloff and Mrs. Lillian Kopeloff, bacteriologist and assistant bacteriologist, have completed a method of preventing deterioration of sugar by molds and bacteria.

It is estimated that about 70,000,000 lb. of the Cuban sugar, valued at \$1,500,000, or enough sugar to supply 873,000 persons for one year, is destroyed annually by the activity of these organisms.

Dr. and Mrs. Kopeloff, by making bacteriological examinations at every stage of the sugar-making process, have found that sugar deterioration can be

prevented by substituting dry or super-heated steam for water in the final process of washing sugar in the drums in which sugar is dried. The centrifugals in their whirling suck up from the floor air which may be contaminated with germs. Also it is common practice to make the color of the sugar lighter by washing the crystals with water which may be contaminated with molds and bacteria.

In the new process it is shown that dry steam is successful in killing over 99 per cent of these avid molds and bacteria.

Water-Power Act Regulations

Due to the length of time required to develop the actual wording of the water-power act regulations which would be satisfactory to all concerned it has been decided to issue a statement of principles. The exact language of the regulations then can be worked out more leisurely. It is expected that another public hearing will be held to go over the final draft of the regulations before their promulgation. This arrangement will allow the committee representing outside interests, of which F. H. Griffith is chairman, to disband for the present.

The Federal Power Commission conducted a hearing on Aug. 24 on the Great Falls project. The water-power act provides that a report must be made before Jan. 1 on this project, which is being relied upon to furnish power for the District of Columbia and for the development of industrial areas in nearby portions of Virginia and Maryland.

All witnesses urged the development of Great Falls except the representative of the Potomac Electric Power Co., who contended that the commercial development of the falls under present conditions would not be feasible.

Difficulties in Obtaining Balloon Gas

The international balloon races which were planned for last month in Indianapolis have been somewhat delayed by the inability to secure the necessary balloon gas at this location. The Air Service is now seeking a new location at which adequate facilities will be available.

The gas required is, of course, one of low specific gravity in order to give high lifting power. Stripped run-of-oven byproduct gas, special coal gas made at high temperature to give low specific gravity, or uncarbureted water gas are the usual supplies employed for these purposes. Gas of a gravity of approximately 0.40 or slightly less is desired for the type of free balloon which is to be used by the contestants. If other means fail, it may be necessary to produce this supply by adding hydrogen to city gas supplies. The hydrogen thus used would have to be manufactured in the portable-type ferrosilicon plants used as field equipment by the Air Service.

Steel Treaters' Convention and Exhibit

A joint meeting of the consolidated American Steel Treaters' Society and the Steel Treating Research Society will be held at the Commercial Museum, 34th and Spruce Sts., Philadelphia, Pa., from Sept. 14 to Sept. 18 inclusive. Throughout the same week and in the same building the societies will sponsor an exhibit of heat-treating appliances and heat-treated products, over 130 firms occupying about 80,000 sq.ft. of floor space. In view of the great success of a like exhibition held last year in Chicago, and the preliminary space reservations, this feature of the event will be of the greatest interest and advantage to the metallurgists in attendance.

Mrs. D. K. Bullens is chairman of the Ladies' Entertainment Committee, and many sight-seeing and social events are being planned. Prominent among them will be trips to historic spots in the vicinity, inspections of Wanamaker's, Curtis Publishing Co., and the Navy Yard.

The exhibition will be open daily from 9 a.m. to 10:30 p.m. Two-hour technical sessions will be held each morning, afternoon and evening on Tuesday, Wednesday and Thursday, except on the latter day, when an informal banquet and entertainment will be given at the Bellevue-Stratford. Friday and Saturday are reserved for inspection trips.

American Institute of Fertilizer Chemists

The first meeting of the American Institute of Fertilizer Chemists since its organization in June at White Sulphur Springs, W. Va., at the annual sessions of the National Fertilizer Association, took place at the Southern Hotel, Baltimore, on Aug. 2 and 3.

Dr. Frank G. Parker, of Charleston, the president, occupied the chair. Others present were: A. G. Stillwell, New York, vice-president; W. J. Gascoyne, Jr., Baltimore, treasurer; Samuel W. Wiley, Baltimore, secretary; Thomas C. Law, Atlanta; Charles W. Rice, Columbia, S. C.; Philip McG. Shuey, Savannah; Ralph W. Bailey, New York; Philip E. Chazal, Charleston; B. H. Morrison, Philadelphia.

At this meeting the work to be done by the institute was discussed at length. The purposes of the organization are to engender among fertilizer chemists a closer and more harmonious relationship; to impress upon the fertilizer trade the fact that the "independent" laboratory is all that the name implies, and that the members of the institute are bound by a code of ethics as rigid as that of other professional bodies, with the penalty of expulsion for transgressions; to provide a means for the members to confer and co-operate in minimizing discrepancies due to personal differences in technique and to secure from fertilizer manufacturers more careful attention to the obtaining of accurate samples of materials for analysis.

A pamphlet giving directions for the correct sampling of the various fertilizer materials will be prepared. The institute will also endeavor to bring about more efficient methods of chemical control at fertilizer plants.

Novel Repair Process

Among the novel repair processes developed by the war is the electrolytic deposition of a thin layer of iron up to one-twelfth of an inch thickness on any simple cylindrical surface of wrought iron or mild or cast steel. Describing the method to the British Institution of Automobile Engineers, B. H. Thomas states that the iron is deposited directly on the surface without any intermediate film of copper, and can be heated to redness without apparent deterioration, can be carbonized or hardened in the ordinary way, can be filed and ground, and takes a high polish. The work being properly done, the adhesion was so strong that the film could not be chipped away from the metal beneath with hammer and chisel. In a heavy repair shop the motor vehicle parts reclaimed in this way included stub axle arms, steering swivel pins, brake and clutch shaft ends, change speed lever shafts, insides of wheel hubs, outside of axles, tubes and universal joint pins. The wearing qualities of the deposit on a high-speed journal do not appear to have been determined. So far the process cannot be used for cast iron or aluminum and its value would be much increased if it could give an adherent coating to such parts as worn gear boxes and ball-race housings.

Groves Endowment Fund for Scientific Research

Charles Edward Groves, F.R.S., editor of the *Journal of the London Chemical Society* from 1884 to 1899 and vice-president of the society from 1899 to 1902, who died on Feb. 1, aged seventy-nine, has left £10,000 to the Royal Institution for the "Groves Endowment Fund" for the promotion of scientific research, to take effect on the death of the last surviving member of his family.

Canada's Sugar Industry

In a recent report of Consul Johnson, stationed at Kingston, it is stated that Canada has eight sugar plants in her provinces, which have a combined annual output of over 650,000,000 lb. Three of these plants are situated in the Province of Ontario, two in Quebec, and one each in British Columbia, New Brunswick and Nova Scotia.

The amount of capital invested in the sugar industry for the whole of Canada in 1918 was \$37,256,851, divided among land, buildings and fixtures, \$17,733,990; machinery and tools, \$6,108,445; materials, stocks in process, finished products, fuel and miscellaneous supplies on hand, \$6,511,626; and cash operating accounts, etc., \$6,902,790. The Ontario plants represented an investment of \$11,407,382, those of Quebec, \$5,869,592 and the remaining provinces, \$19,979,877.

The accompanying tables show the quantity and value of material used at the plant in 1918 and the quantity and value of the finished products:

QUANTITY AND VALUE OF MATERIAL		
Classes of Materials	Tons	Net Value at Works
Beets	204,017	\$2,593,715
Raw sugar	313,651	39,991,144
Bone black and other materials		529,059
Boxes, bags and other containers		2,289,119
Total value		\$45,403,037

QUANTITY AND VALUE OF FINISHED PRODUCTS		
Kinds of Products	Quantity	Value
Sugar, granulated, lb.	651,940,965	\$57,080,533
Molasses or sirup, gal.	1,559,694	1,016,626
Beet pulp, tons	11,069	411,645
Lime, bushels	22,590	6,250
Fertilizers, tons	1,284	43,073
Cattle food		151,776
All other products		102,494
Total value		\$58,812,219

Japanese Exports of Calcium Carbide

Due to war conditions the exports in 1918 of calcium carbide, which is shipped chiefly to Australia, British India and China, amounted to 28,844,680 lb., valued at 5,476,000 yen, the 1919 exports falling to 3,399,904 lb., valued at 525,240 yen, while the 1920 exports run about the same as in 1919. As electric power costs at least 8 sen per kw., the cost of production of calcium carbide is about 5 sen per lb., and it is believed that unless the cost of electric power is reduced to less than 7 sen per kw. and the calcium carbide is improved in quality the Japanese product will find difficulty in meeting foreign competition.

Movement of Nitrate of Soda

During June, 109,953 tons of nitrate of soda moved through the Panama Canal. With the exception of three cargoes, which went to the United Kingdom, all of the nitrate was consigned to Atlantic ports of the United States.

Four cargoes of sulphur from the Louisiana and Texas fields passed through the canal during June destined to Portland, Ore., Vancouver, B. C., and Melbourne, Australia.

Tests Made of Firebricks

Tests made at the Columbus Experiment Station of the Bureau of Mines have developed the fact that firebrick with the highest alumina content last longest when used in malleable iron furnaces. Hot crushing strength tests were made of a number of varieties of firebrick.

Personal

P. W. BOUTWELL, assistant professor of agricultural chemistry at the University of Wisconsin, Madison, Wis., has been appointed associate professor of chemistry at Beloit College, Beloit, Wis.

Dr. F. G. COTTELL, the director of the Bureau of Mines, in order to determine the moot question of the subjects to be handled at the new Mine Experiment Station at Tuscaloosa, Ala., will confer with the officials of the University of Alabama about the middle of September and gather first-hand information as to what subjects had best be handled at this station.

T. LINSEY CROSSLEY has become editor of the *Canadian Chemical Journal*, which is the official organ of the Canadian Institute of Chemistry.

R. E. DOOLITTLE spoke before the Chicago Chemists' Club recently on "Botulism and Proper Preparation of Ripe Olives."

General AMOS A. FRIES, chief of the Chemical Warfare Service, and Colonel E. J. Atkisson, the commander of Edgewood Arsenal, along with four or five other officers of the Chemical Warfare Service, will attend the meeting of the American Chemical Society in Chicago.

M. J. GAVIN, refinery engineer of the U. S. Bureau of Mines, who has been in Washington, has returned to his station at Salt Lake City.

RALPH A. GOULD, chemical engineer, 216 Pine St., and BRYANT S. DRAKE, chemical engineer, 14 Montgomery St., San Francisco, Cal., announce their association, from Aug. 1, 1920, in a partnership under the name of Gould & Drake, chemical engineers, with offices at 216 Pine St., San Francisco, Cal.

ERNEST J. HOPKINS, who recently resigned as assistant chemist, U. S. Bureau of Mines, Pittsburgh, Pa., has accepted a position in organic research with W. B. Pratt, Inc., Boston, Mass.

Dr. DAVID KLEIN, who was formerly associate professor of biochemistry in the Johns Hopkins University School of Public Health and Hygiene, is now with the Hollister-Wilson Laboratories, Chicago, Ill., as director of research and control laboratories.

A. T. MARCH has recently returned from Namtu, Upper Burma, India, where he has for the past several years been in charge of the silver refining for the Burma Mines, Ltd.

H. B. NORTHRUP has resigned his position as associate professor of metallurgy at the Penn State College, State College, Pa., to become chief metallurgist for the Diamond Chain & Mfg. Co.

ROBERT J. QUINN has recently severed connection with A. Daigger & Co. to become associated with the Mathieson Alkali Co., of Chicago, as district manager. Mr. Quinn is a graduate of chemical engineering at the University of Illinois, was subsequently chief chemist with Morris & Co., packers; later he became associated with the Wahl Henius Institute, consulting engineer in charge of packing department, and left to take a position with the Midland Chemical Co. His new address is 617 Webster Bldg., Chicago, Ill.

Dr. J. H. RANSOM, director of chemical research at the Michigan Smelting & Refining Co., Detroit, Michigan, recently delivered a lecture on non-ferrous alloys before the students of the school of chemical engineers, Purdue University.

RICHARD R. REES, who was formerly chief metallurgical chemist at the U. S. Arsenal, Watervliet, N. Y., and not chief metallurgist as erroneously given in this column in our last issue, is now with the Neptune Meter Co., Long Island City, N. Y.

Dr. WALDEMAR T. SCHALLER has severed his connection with the Great Southern Sulphur Co., Inc., of New Orleans,

La., and has returned to the U. S. Geological Survey, Washington, D. C.

C. N. SHUETTE, recently superintendent of the Mariscal quicksilver mine in Texas, has rejoined the staff of the U. S. Bureau of Mines at Berkeley, Cal.

Dr. E. WARD TILLOTSON of the Mellon Institute is accompanying the members of the Institute of Glass Technologists who are here from England on their itinerary to the glass factories of the Eastern United States.

R. M. WILHELM, who has been chief of the thermometer laboratory of the National Bureau of Standards, has resigned to accept a position with C. J. Tagliabue Manufacturing Co., Brooklyn, N. Y. Mr. Wilhelm will begin work in his new position about the first of September.

W. WOODWARD WILLIAMS has resigned as vice-president of the Redding Iron Co. effective Sept. 1, when he will become assistant to the president of the Pittsburgh Gage & Supply Co.

Obituary

REGINALD K. PIERCE, secretary of the Semet-Solvay Co. and of the Kentucky Solvay Co., in an attempt to avoid an accident was killed near Oran, N. Y., on Sunday evening, Aug. 15, while driving a high-powered roadster which turned over in a ditch as he tried to avoid a collision with a smaller machine. Mr. Pierce was instantly killed. He was a brother of Edward L. Pierce, president of the Semet-Solvay Co. and the Kentucky Solvay Co., and had been associated with these companies for about twelve years, holding several important offices. He was elected secretary and sales manager of the companies about three years ago and was serving in these capacities at the time of his death. He was forty-two years old. He leaves three brothers, Edward L. Pierce of the Solvay companies; Charles Pierce of Boston, counsel for the New England Telephone Co., and George Pierce, a prominent Boston physician.

JAMES WILSON, who served as Secretary of Agriculture for fifteen years, died on Aug. 26 at Traer, Iowa, after an illness of many weeks.

Book Reviews

WATER POWERS OF BRITISH COLUMBIA. By Arthur V. White, assisted by Charles J. Vick. 644 pp. and maps, illus. Ottawa: Commission of Conservation.

This is part of an exhaustive study undertaken by the Commission of Conservation to prepare a complete inventory of the water-power resources of Canada. The work was begun in 1910 and has resulted in publication of volumes on Water Powers of Canada, Water Powers of Manitoba, Saskatchewan and Alberta and the current volume of Water Powers in British Columbia. The estimated total of horsepower in the latter province is 2,500,000. The commission calls attention to the fact, however, that the grand totals representing horsepower possibilities for large sections of a country are apt to be misleading. Furthermore in the development of water power it must be recognized that such interests as domestic and municipal water supply, agriculture, irrigation and navigation, fisheries, mining and riparian rights are dependent on the same source. The volume contains a chapter on water legislation in British Columbia and another on rules and regulations for the development of power. A separate chapter is devoted to the topography of power-site tables of the Columbia, Fraser and MacKenzie rivers, Vancouver Island and mainland Pacific coast. Other chapters are devoted to stream flow data, and another on meteorological data. The book will be of distinct value to companies contemplating the development of water power in Canada or to industries which require water power in their operations. H. C. PARMETER.

Current Market Reports

The Iron and Steel Market

Pittsburgh, August 27, 1920.

In the past week or two the iron and steel market has exhibited itself as quite lacking in definite motive or substantial basis. Nearly everything that occurs has a distinct opportunist coloring. For illustration, pig-iron prices in most districts have been shoved upward, when prices were already too high for safety in proportion to steel prices. Those who were in the market as buyers were not particular as to prices, since they were buying only for urgent requirements of the present or near future. Again, the steel market cannot be regarded as really on a rational basis until the selling prices of the Steel Corporation and the independents are together, or at least not far apart, but the gap is not being bridged. That it is possible for the two sets of prices to exist side by side is due to the fact that the markets are entirely different in point of delivery, and the difference in time of delivery has been widening. At the beginning of the year, when the departure of the independent prices from the Steel Corporation prices became clearly marked, the corporation had 8,000,000 tons of unfilled business on books, while now it has 11,000,000 tons. The independents were then able to sell much more week by week than they were producing, whereas of late their sales have run well below their shipments. In other words, it requires a greater promptness of delivery, compared with a Steel Corporation delivery, to enable an independent to get the extra price.

Illustrative of the peculiar alignments in the market, the Industrial Board prices of March 21, 1919, may be taken as a basis. The prices in that schedule were fairly well proportioned. The Steel Corporation prices are Industrial Board prices exactly. Prices obtained lately by independent mills on steel products run about \$20 a ton, or about 30 per cent, above the Industrial Board prices, while prices of pig iron with the latest advances average about 75 per cent above the Industrial Board figures. Before the event one could scarcely have conceived the possibility of such price relations existing even for a moment, let alone of their continuing with no signs of the law of supply and demand working toward a readjustment.

DULL MARKETS

Apart from the activity in pig iron, which has been in prices more than in tonnage turnover, since prices advanced on a relatively small amount of buying, the iron and steel markets generally have been very dull, and even more stagnant than they were earlier in this midsummer period. It seems to be clearly established now that the dullness is not associated closely with the season of the year but is a product of more fundamental conditions, including the state of business generally and the awkward position into which prices have worked themselves.

Such demand for steel as is exhibited is confined almost wholly to the deliveries that are very difficult to get. The independent sheet mills are sold through November and about 40 per cent into December, according to their computation, and there is insistent demand for sheets even for October and November delivery. Plates, on the other hand, can be obtained for delivery in a very few weeks and there is scarcely any demand for plates. One can buy plates at 3.25c., although some mills ask 3.50c. and higher. Early in the year plates commanded much higher prices than merchant bars, but now bars in the smaller sizes are "scarce" and there is ready sale at 3.50c., sometimes at still higher prices. Shapes can be had at 3.10c. and are entirely neglected.

The report for July of the Bridge Builders' and Structural Society shows bookings of fabricated steel contracts during the month at 50 per cent of the fabricating capacity,

this corresponding with the report for June. The continued dullness in this line is practically unprecedented.

Railroad demand has not developed in volume, and is hardly expected for some time to come. Car buying is almost entirely confined to industrial companies and thus does not run into volume. There is a fair running demand for steel for car repairs.

TRANSPORTATION IMPROVING

Transportation conditions continue to improve. Mills are now reducing their accumulated stocks of steel, produced against orders but held on account of car shortage, whereas until late in July there were almost constant additions to stocks. The movement, however, may be considered as one in quantity rather than in quality. The shipments that leave the mills are good, but on account of embargoes and other restrictive influences the distribution is poor, some consumers receiving very good shipments and others very light shipments.

It is a common view in iron and steel circles that the railroads are "set" for a great improvement in physical operations, now that Sept. 1 is so near at hand, this being the date upon which the railroads must begin making their revenue themselves. The Interstate Commerce Commission has ordered that sixty open-top cars be furnished daily to pipe mills in the Pittsburgh and Youngstown districts, for moving oil-country goods to the South and Southwest.

SEMI-FINISHED STEEL

In the East several thousand tons of standard billets have been sold on the basis of \$60 Pittsburgh, a figure that was difficult for a buyer to get two or three weeks ago and was practically impossible a month ago. Several sales of sheet bars have been made at \$67.50 Pittsburgh, when \$75 was the market a few weeks ago. Semi-finished steel has been declining, while pig iron, metallurgically the raw material, has been advancing.

In nearly all districts pig-iron prices have been advancing, and sharply at that, though the sales are in thousands of tons when tens of thousands of tons have hitherto figured when prices were advancing. Small transactions in valley bessemer and basic, just running into four figures, have established those grades at \$48.50 valley, or \$1.50 advance in bessemer and \$2 advance in basic, while foundry remains at \$50 valley, to which it advanced recently by a \$4 jump.

In the past few days slight signs have appeared perhaps portending a weakening in prices, or at any rate a refusal of consumers to follow the market. Southern iron in the past generally took the lead of pig iron in general in advances and declines, and it may be significant therefore that Southern iron did not advance in the past two or three weeks, when the valley, eastern Pennsylvania, Buffalo and other markets were advancing, while it is now said that there are more sellers of Southern iron at the \$42 minimum, and fewer at premiums over this price, than ten days ago.

The Chemical and Allied Industrial Markets

New York, August 27, 1920.

There has been very little activity in the chemicals during the week—in fact, dealers and handlers report they have done nothing in the way of actual business. The acid branch is in about the same condition, suffering from lack of interest that has been apparent for some time. It is a peculiar fact that in spite of the present weakness prices are practically the same as in the last report, with the following exceptions noted:

	Today	Week Ago	Year Ago
Oxalic, crystals	\$0.53 @0.57	\$0.55 @0.60	\$0.25 @0.30
Lactic, 44 per cent.	0.10 @0.11	0.11 @0.12	0.11 @0.14
Salammoniac, white.	0.15 @0.16	0.16 @0.16	0.12 @0.13
Copperas	2.00 @2.50	2.50 @3.00	1.00 @1.20
Potassium sulphate	2.40 @2.55	2.25 @2.40	2.25

Methyl alcohol, to be listed hereafter as methanol, is nominally quoted \$3.25@3.30 for 95 per cent and \$3.50@3.55 per gal. for the pure grade. The Government restrictions placed on the sale of this article are so stringent that it has become very difficult for a small buyer to make a purchase, while ethyl alcohol because of scarcity is nominally quoted around \$5.50@\$5.75 per gal. In line with

these prices *formaldehyde* is still firm at 48c. in car lots and 50c. in less than car lots. The above figures are manufacturers' prices and have been in force for some time, but small quantities that have been on the market for some time can be obtained as low as 40c. per lb.

• COAL-TAR PRODUCTS

Prices have been well sustained during the period despite the very inactive condition of the market. The present situation of the spot market is the antithesis of that prevailing a few months ago, when it was practically impossible to obtain any of the crudes or intermediates for prompt delivery. Now the spot demand is so small that business is at a standstill and wherever a likely purchaser is found generous concessions are made on the prevailing prices. Producers are progressing rapidly and most of them are in a fair way to catch up on back contracts which had to remain untouched under the pressure of recent conditions.

NAVAL STORES

An unusual condition exists in the *rosin* market inasmuch as the lowest grade, B, is selling 10c. higher than any of the other grades. Grades D to W are all quoted at \$14.50, and this price, it is expected, will prevail for some time. This situation has been brought about by an excessively heavy demand for the lower grades from South America, where it is used in manufacturing soaps and varnishes. The domestic demand for the higher grades which are used for the same purpose has fallen off to such an extent that there is surplus on hand, thus lowering the price to the same level as the B-I grades. The supply in the local market is ample to meet the demand, which has been very light recently. *Turpentine* is also weaker, with a 5c. drop recorded from last week's \$1.60 mark. This has been caused by two elements, the light buying interest and the uncertainty existing in the Savannah market. Buyers are holding back and are evidently expecting lower prices in this commodity.

OILS

This market is practically at a standstill, as buyers are either well taken care of or are holding out for still lower levels. Prices on the list are nominal, as concessions can be obtained on almost all of the quotations listed. *Linseed* has still further declined and current prices are: \$1.43 in less than car lots; \$1.37@ \$1.40 in car lots. Whatever buying that is being done is for actual requirements only, and on a spot basis. There has been very little interest manifested in futures, and this condition is expected to prevail for a few weeks more at least.

The Chicago Market

Chicago, August 25, 1920.

The situation in the local market is no different from that in the rest of the country in that the entire trade—buyers, dealers and manufacturers—is engaged in watchful waiting. A feeling of uncertainty as to the future trend of prices is acting as a stop on trading, and this cessation of business in itself gives the market a weak tendency, as all holders of stock, particularly re-sellers, are desirous of moving goods.

This uncertain feeling is most pronounced in regard to vegetable oils. Enormous imports of flaxseed from the Argentine, coupled with a large crop in Canada and the Northwest, tends to make the future of linseed oil a little dubious. A heavy cotton crop coming up and an immense carry-over of cottonseed oil from last year combine to make present prices look too high, and Oriental financial troubles make anything possible in the copra and coconut oil trade. Other oils, in sympathy, are correspondingly weak and uncertain.

Among the heavy chemicals, the *alkalis*, former leaders in high prices, are at a standstill, traders and buyers alike apparently awaiting the issuance of 1921 quotations by makers. Chemical manufacturers in general claim to look for higher prices, while buyers are equally strong in the opinion that the peak has already been passed. This

renders the one not anxious to sell and the other unwilling to buy, hence the stagnant market.

In the main, 'railroad service is good, though some complaint is heard from the fertilizer and acid people. Imposition of the new tariffs will undoubtedly have some effect on prices, although the extent will remain unknown until the manufacturers and dealers have had time to study the rates.

HEAVY CHEMICALS

The *alcohols* remain unchanged during the past month. *Ethyl* grade, at \$5.52½ in five barrel lots, \$5.57½ in single barrels, is firmly held, and but little is changing hands. *Methanol* (methyl alcohol), 95 per cent, is quoted at \$3.35@ \$3.65 per gal., but this quotation means little, as it is practically unobtainable. *Denatured* is a little freer in movement at \$1.09 per gal. *Formaldehyde* has reflected recent fluctuation in the Eastern market by a decline last week to 51c. followed by a stronger market this week, today's price being 53c. This is a net decline of 2c. since the first of the month, and in view of the relatively high price and the scarcity of *methyl alcohol* a recovery is not improbable.

Copper sulphate continues to show good business at 9c. per lb. in car lots. Should export demand increase, higher prices can be expected. *Copper carbonate* is firm at 27c., solely on account of cost of production, as demand is very light. *Copperas* is offered at \$2.35 per cwt., f.o.b. works, with no takers, and spots are quoted at \$2.75, with considerable shading being necessary to induce business. *Arsenic* is uncertain in price, tending to lower levels. Current transactions in *white arsenic* are reported at about 15c. per lb. and red is going at 19@20c. Supply is quite free and futures can be engaged at 1@2c. lower on both kinds.

Bleaching powder, still hard to get, is alone among the alkalis in holding firm. It is quoted today at around 7c. per lb., being available in extremely limited quantities only. *Soda ash*, selling weakly on the spot at \$3.15@ \$3.25 per cwt., is still quoted by makers at \$3.35. Not much business is being closed at that figure. *Caustic soda* is in good supply and the price continues weak at 5½c. per lb. or less. Much interest is noted in the price to be set by producers on 1921 goods. Not much free *sal soda* is in the market and current quotations are fairly firm at 2c. per lb.

A little better market is noted the last few days in the *acids*, but prices in general are weak and subject to shading. Definite quotations are hard to get. *Acetic acid*, 28 per cent, commercial, is bringing \$3.65@ \$3.75 per cwt., export *carbolic* is quoted all the way from 12@15c. and *sulphuric*, 66 degree, is still quoted at \$22 per ton.

COAL-TAR PRODUCTS

Very slow market continues the rule in Chicago with no sensational price changes. The apparent approaching end of the Russo-Polish war has a weakening tendency which, in the face of prevailing high prices, discourages any active trading. *Benzol* is quoted at 38c. per gal. for spot deliveries, but some shading is in evidence. *Cresol*, held strongly at 18½@19c., is not very plentiful and *toluol* is equally firm at 37c., though but little actual movement is noted in any of these crudes. *Aniline oil* is off for sales from local stock, sales as low as 30c. per lb. being recorded and future offers being made at 28c. Light demand is making holders of second hands willing to shade prices. The same is true of *aniline salt*, which is quoted down to 38c. this week. *Benzoic acid* is in good demand at 90c. per lb. for U. S. P., and *benzaldehyde* is correspondingly strong at 68c. per lb. for the technical, \$2.30@ \$2.50 for F.F.C.

NAVAL STORES

The market in general is a little slower, although local dealers are still disposing of goods as rapidly as they are received. Rail conditions are no longer a problem, shipments moving easily. Current quotation on *turpentine* is \$1.62@ \$1.63 per gal., 13c. less than at the first of the month, while *pine oil*, both pure and destructively distilled, remains firm at \$1.90. *Rosin* is off a shade on all grades, current transactions ranging from \$15.75@ \$16 in less than car lots.

VEGETABLE OILS

Holders of stock are facing heavy shrinkages in value, as prices continue to decline with still no buyers to take advantage of them. *Linseed oil* quotations cover a wide range, \$1.40 per gal. apparently being as close a quotation as is obtainable. *Red oil*, with the disappearance of consumers from the market, finds no buyers at 12c. and *cottonseed oil*, facing an enormous production this fall, is down to 16c. or even less for refined and deodorized. Orientals are holding slightly more firm, *soya bean oil* being quoted at 9½c., seller's tanks, f.o.b. coast and *coconut oil* at 13c. On the latter product, local price is firm at 17½c. for spots.

The Baltimore Market

Baltimore, Md., August 26, 1920.

During the past two weeks there have been a number of developments which have tended to depress the fertilizer market. Farm products for the first time in a number of years have been selling at or below cost of production, resulting in some of the farmers deciding not to harvest certain crops. This will in turn seriously affect payment of fertilizer bills, and practically the entire trade has decided in view of unsettled conditions to defer future purchases of materials, awaiting further developments.

On account of the heavy crop of cotton seed and lack of demand from either fertilizer or feed manufacturers, the market on *cottonseed meal* has further declined, and no immediate relief seems to be in sight. The prospects of finding an outlet for export are not very encouraging, first, on account of the present foreign exchange situation, and secondly, because European vegetable meals are obtainable there on a lower basis than prevailing prices in this country. Prime *cottonseed meal* is now obtainable for September-December shipment as low as \$7.75 per unit based on the increased freight rates, which amount to about 50c. per unit. This difference, therefore, about represents the decline in the market during the past two weeks.

ACID PHOSPHATE

No important changes have taken place in this article, and it is one of the few materials that is not affected by the present depression, on account of the well sold up condition of the market, and many of the dry mixers still have to cover for their requirements. It is anticipated that the market on *acid phosphate* will remain stationary, at least for the immediate future, and October-December is still nominally quoted at \$19@20 per ton, in bulk, basis 16 per cent.

TANKAGE

Prices on this commodity are ruling easier, and it is now possible to secure Eastern ground tankage at about \$7.60@7.75 and 10c. c.a.f. Baltimore, which price, however, is lower than the Western product can be delivered here. *Foreign nitrogenous material*, however, is obtainable at \$7.25 per unit of ammonia delivered Baltimore, with no buying interest being manifested.

NITRATE OF SODA

The market is easy and September-October deliveries are nominally quoted at \$3.65@3.70, November-December \$3.75@3.80, and January-April \$3.90@3.95. It is reported that the present favorable low rates of sterling exchange are responsible for the decreased prices.

POTASH

Practically the entire trade is playing the waiting game, and it is expected that this will have the desired effect in the near future. There is practically no demand for spot deliveries, and August-September arrivals of *muriate* are quoted at \$2.40, *manure salt* at \$1.95 and *kainit* at \$2.05, without any important sales.

FISH SCRAP

None of this material is at present pressing on the market either from producers or second hands, and the market remains at \$7.50 and 10c. for dry *unground scrap* f.o.b. fish factories.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride..... lb.	-	\$0.65 - \$0.75
Acetone..... lb.	\$0.15 - \$0.20	.21 - .22

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....	lb. \$1.40 - \$1.50
Alpha naphthol, refined.....	lb. 1.60 - 1.70
Alpha naphthylamine.....	lb. .50 - .52
Aniline oil, drums extra.....	lb. .30 - .33
Aniline salts.....	lb. .35 - .40
Anthracene, 80% in drums (100 lb.).....	lb. .90 - 1.00
Benzaldehyde (f. f. c).....	lb. 2.00 - 2.10
Benzidine, base.....	lb. 1.35 - 1.40
Benzidine, sulphate.....	lb. 1.15 - 1.25
Benzole acid, U. S. P.....	lb. .85 - .90
Benzonate of soda, U. S. P.....	lb. .80 - .90
Benzol, pure, water-white, in drums (100 gal).....	gal. .38 - .40
Benzol, 90%, in drums (100 gal).....	gal. .36 - .38
Benzyl chloride, 95-97%, refined.....	lb. .35 - .40
Benzyl chloride, tech.....	lb. .25 - .35
Beta naphthol benzoate (nominal).....	lb. 3.50 - 4.00
Beta naphthol, sublimed (nominal).....	lb. .85 - .95
Beta naphthylamine, sublimed.....	lb. 2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.).....	lb. .18 - .25
Ortho-cresol, in drums (100 lb.).....	lb. .23 - .25
Crocylic acid, 97-99%, straw color, in drums.....	gal. 1.15 - 1.20
Crocylic acid, 95-97%, dark, in drums.....	gal. 1.05 - 1.10
Crocylic acid, 50%, first quality, drums.....	gal. .65 - .75
Dichlorobenzol.....	lb. .08 - .10
Diethylamine.....	lb. 1.50 - 1.60
Dimethylamine.....	lb. 1.00 - 1.05
Dinitrobenzol.....	lb. .30 - .37
Dinitrochlorobenzol.....	lb. .32 - .35
Dinitronaphthalene.....	lb. .45 - .55
Dinitrophenol.....	lb. .40 - .45
Dinitrotoluol.....	lb. .40 - .45
Dip oil, 25% tar acids, car lots, in drums.....	gal. .38 - .40
Diphenylamine (nominal).....	lb. .80 - .85
II-acid (nominal).....	lb. 2.00 - 2.25
Metaphenylene diamine.....	lb. 1.25 - 1.30
Monochlorobenzol.....	lb. .18 - .20
Monochloro aniline.....	lb. 2.00 - 2.40
Naphthalene crushed, in bbls. (250 lb.).....	lb. .19 - .19
Naphthalene, flake.....	lb. .75 - .85
Naphthalene, balls.....	lb. .14 - .19
Naphthyl ole acid, crude.....	lb. .40 - .50
Nitr benzol.....	lb. .18 - .25
Nitro-naphthalene.....	lb. .35 - .45
Nitro-toluol.....	lb. 3.25 - 4.25
Ortho-amidophenol.....	lb. .15 - .20
Ortho-dichlorobenzol.....	lb. .80 - .85
Ortho-nitro-phenol.....	lb. .25 - .30
Ortho-nitro-toluol.....	lb. .25 - .30
Ortho-toluol.....	lb. 2.50 - 3.00
Para-amidophenol, base.....	lb. 2.50 - 3.00
Para-amidophenol, HCl.....	lb. .08 - .12
Para-dichlorobenzol.....	lb. 1.10 - 1.20
Paranitraniline.....	lb. 1.10 - 1.20

Para-nitro-toluol.....	lb. 1.35 - 1.50
Paraphenylenediamine.....	lb. 2.50 - 2.65
Paratoluidine.....	lb. 2.00 - 2.25
Phthalic anhydride.....	lb. .60 - .70
Phenol, U. S. P., drums (dest.), (240 lb.).....	lb. .12 - .20
Pyridin.....	gal. 2.00 - 3.50
Roserein, technical.....	lb. 4.25 - 4.5
Roserein, pure.....	lb. 6.25 - 6.75
Salicylic acid, tech., in bbls. (110 lb.).....	lb. .50 - .52
Salicylic acid, U. S. P.....	lb. .50 - .61
Salol.....	lb. .90 - 1.00
Solvent naphtha, water-white, in drums, 100 gal.....	gal. .33 - .35
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal. .23 - .26
Sulphanilic acid, crude.....	lb. .32 - .35
Toluidine.....	lb. 1.70 - 2.50
Toluidine, mixed.....	lb. .45 - .55
Toluol, in tank cars.....	gal. .35 - .40
Toluol, in drums.....	gal. .38 - .40
Xylidine, drums, 160 gal.....	lb. .50 - .65
Xylol, pure, in drums.....	gal. .47 - .50
Xylol, pure, in tank cars.....	gal. .45 - .50
Xylol, commercial, in drums, 100 gal.....	gal. .32 - .35
Xylol, commercial in tank cars.....	gal. .30 - .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....	lb. \$0.36 - \$0.39
Beeswax, refined, light.....	lb. .37 - .38
Beeswax, white pure.....	lb. .63 - .68
Carnauba, No. 1, (nominal).....	lb. .90 - .95
Carnauba, No. 2, regular (nominal).....	lb. .85 - .85
Carnauba, No. 3, North Country.....	lb. .35 - .36
Japan.....	lb. .17 - .18
Montan, crude.....	lb. .25 - .26
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb. .09 - .09
Paraffine waxes, crude, scale 124-126 m.p.....	lb. .09 - .10
Paraffine waxes, refined, 118-120 m.p.....	lb. .11 - .11 1/2
Paraffine waxes, refined, 125 m.p.....	lb. .12 - .12
Paraffine waxes, refined, 128-130 m.p.....	lb. .13 - .15
Paraffine waxes, refined, 133-135 m.p.....	lb. .16 - .17
Paraffine waxes, refined, 135-137 m.p.....	lb. .17 - .18 1/2
Stearic acid, single pressed.....	lb. .20 - .21
Stearic acid, double pressed.....	lb. .22 - .23
Stearic acid, triple pressed.....	lb. .24 - .25

NOTE—Paraffine waxes very scarce.

Flotation Oils

All prices are f. o. b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal. \$2.15
Pine oil, pure, dest. dist.....	gal. 1.80
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal. .48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f. o. b. Jacksonville, Fla.....	gal. .35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal. .85
Pine tar, ref., thin, sp. gr. 1.080-1.060.....	gal. .36
Turpentine, crude, sp. gr. 0.900-0.970.....	gal. 1.75
Hardwood oil, f. o. b. Mich., sp. gr. 0.960-0.990.....	gal. .35
Pineewood creosote, ref.....	gal. .52

Naval Stores

The following prices are f. o. b., New York, for carload lots.

Rosin B-D, bbl.....	280 lb. \$14.60 -
Rosin E-I.....	280 lb. 14.50 -
Rosin K-N.....	280 lb. 14.50 -
Rosin W. (I-W. W.).....	280 lb. 14.50 -
Wood rosin, bbl.....	280 lb. 15.00 -
Spirits of turpentine.....	gal. 1.55 -
Wood turpentine, steam dist.....	gal. -
Wood turpentine, dest. dist.....	gal. -
Pine tar pitch, bbl.....	200 lb. 8.50 -
Tar, kiln burned, bbl. (500 lb.).....	bbl. 14.50 - 15.00
Tar, sort tar, bbl.....	500 lb. 15.00 - 15.50
Rosin oil, first run.....	gal. .72 -
Rosin oil, second run.....	gal. .75 -
Rosin oil, third run.....	gal. .92 -

Solvents

75-76 deg., steel bbls. (45 lb.).....	gal. \$0.40
70-72 deg., steel bbls. (85 lb.).....	gal. .38
68-70 deg., steel bbls. (85 lb.).....	gal. .37
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal. .29

Crude Rubber

Para—Upriver fine.....	lb. \$0.29 - \$0.31
Upriver coarse.....	lb. .19 - .20
Upriver caucho ball.....	lb. .20 - .22
Plantation—First latex crepe.....	lb. .30 -
Ribbed smoked sheets.....	lb. .28 -
Brown crepe, thin, clean.....	lb. .26 -
Amber crepe No. 1.....	lb. .28 -

Oils

VEGETABLE

The following prices are f. o. b., New York for carload lots.

Castor oil, No. 3, in bbls.....	lb. \$0.16 - \$0.18
Castor oil, AA, in bbls.....	lb. .19 - .19
China wood oil, in bbls.....	lb. .17 - .18
Cocanut oil, Ceylon grade, in bbls.....	lb. .15 - .16
Cocanut oil, Cochon grade, in bbls (nominal).....	lb. .16 - .16
Corn oil, crude, in bbls.....	lb. .14 - .15
Cottonseed oil, crude (f. o. b. mill).....	lb. .10 - .11
Cottonseed oil, summer yellow.....	lb. .12 - .13
Cottonseed oil, winter yellow.....	lb. .17 - .18
Linseed oil, raw, car lots (domestic).....	gal. 1.40 - 1.43
Linseed oil, raw, tank cars (domestic).....	gal. 1.37 - 1.40
Linseed oil, boiled, car lots (domestic).....	gal. 1.48 - 1.50

Olive oil, commercial.....	gal.	3 00	—	3 10
Palm, Lagos.....	lb.	.10	—	.10
Palm, bright red.....	lb.	.10	—	.10
Palm, Niger.....	lb.	.11	—	.12
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.12	—	.12
Peanut oil, refined, in bbls.....	lb.	.17	—	.18
Rapeseed oil, refined in bbls.....	gal.	1 40	—	1 50
Rapeseed oil, blown, in bbls.....	gal.	1 60	—	1 70
Soya bean oil (Manchurian), in bbls, N. Y.....	lb.	.14	—	.14
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.09	—	.11

FISH

Winterpressed Menhaden.....	gal.	\$0.90	—	\$1.05
Yellow bleached Menhaden.....	gal.	0.95	—	1.05
White bleached Menhaden.....	gal.	1.00	—	1.25
Blown Menhaden.....	gal.	1.00	—	1.20

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$22.00	—	\$25.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	18.00	—	20.00
Barytes, crude, 88% (94% ba.), Kings Creek	net ton	8.00	—	10.00
Barytes, ground, white, f.o.b. Cartersville, Ga.	net ton	23.00	—	25.00
Barytes, ground, off-color, f.o.b. Cartersville	net ton	16.00	—	19.00
Barytes, crude, 88% (94% ba.), Cartersville	net ton	12.00	—	14.00
Barytes, floated, f.o.b. St. Louis	net ton	26.50	—	28.00
Barytes, crude, min. 98% ba., Missouri	net ton	11.00	—	11.25

Refractories

Chrome brick, f.o.b. Chester, Pa., carlots	net ton	90	—	100
Chrome brick, 9-in. str. and sizes, f.o.b. Baltimore	net ton	90	—	95
Fire clay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	50	—	55
Fire clay brick, 1st quality, f.o.b. St. Louis	1,000	45	—	—
Fire clay brick, 1st quality, f.o.b. New Jersey	1,000	75	—	—
Fire clay brick, 2d quality, 9-in. shapes f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	4	—	55
Magnesite brick, 9-in. straights, f.o.b. Baltimore	net ton	100	—	110
Magnesite brick, 9-in. sizes and shapes larger than 9-in.	net ton	90	—	100
Magnesite brick, f.o.b. Chester	net ton	90	—	100
Silica brick, 9-in. and 9-in. sizes, Chicago district	1,000	55	—	—
Silica brick, f.o.b. Birmingham	1,000	51	—	55
Silica brick, f.o.b. Mt. Union, Pa.	1,000	55	—	60

Ferro-Alloys

All f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	\$200.00	—	\$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon, carlots	lb.	18	—	19
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon, carlots	lb.	20	—	21
Ferro-manganese, 76-80% Mn, domestic	gross ton	175.00	—	225.00
Ferro-manganese, 76-80% Mn, English	gross ton	190.00	—	240.00
Spiegel, 18-22% Mn	gross ton	75.00	—	—
Ferro-molybdenum, 50-60% Mo, per lb. of Mo.	lb.	2.25	—	2.75
Ferro-silicon, 10-15%	gross ton	60.00	—	65.00
Ferro-silicon, 50%	gross ton	80.00	—	90.00
Ferro-silicon, 75%	gross ton	150.00	—	160.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	1.10	—	1.15
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	7.00	—	—
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	6.50	—	7.75

Ores and Semi-finished Products

All f.o.b. Mines, Unless Otherwise Stated

Bauxite, 52% Al. content, less than 2% Fe ₂ O ₃ , up to 20% silica, not more than 11% moisture	gross ton	\$10.00	—	\$11.00
Chrome ore, Calif. concentrator, 50% min. Cr ₂ O ₃	unit	60	—	.65
Chrome ore, 40% min., Cr ₂ O ₃ , f.o.b. Atlantic seaboard	unit	.77	—	.85
*Coke, foundry, f.o.b. ovens	net ton	20.00	—	—
*Coke, furnace, f.o.b. ovens	net ton	18.00	—	20.00
*Coke, petroleum, refinery, Atlantic seaboard	net ton	24.00	—	—
Fluor spar, lump, f.o.b. Tonuco, New Mexico	net ton	17.50	—	—
Fluor spar, standard, domestic washed gravel	net ton	25.00	—	27.50
Ilmenite, 52% TiO ₂ , per lb. ore	lb.	.011	—	.85
Manganese Ore, 50% Mn, c. f. Atlantic seaport	unit	70	—	.80
Manganese ore, chemical (MnO ₂)	gross ton	75.00	—	.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.	lb.	.75	—	.85
Monazite, per unit of ThO ₂	unit	42.00	—	—
Pyrites, Spanish, fines, c. f. Atlantic seaport	unit	12	—	—
Pyrites, Spanish, furnace size, c. f. Atlantic seaport	unit	.16	—	—
Pyrites, Spanish, run of mines, c. f. Atlantic seaport	unit	12	—	14
Pyrites, domestic, fines	unit	12	—	14
Rutile, 95% TiO ₂ , per lb. ore	lb.	.15	—	—
Tungsten, Scheelite, 60% WO ₃ and over, per unit of WO ₃	unit	7.00	—	—
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃ , N. Y. C.	unit	6.00	—	7.00
Uranium Ore (Carnotite) per lb. of U ₃ O ₈	lb.	2.75	—	3.00
Uranium oxide, 96% per lb. contained U ₃ O ₈	lb.	2.75	—	3.00
Vanadium pentoxide, 99%	lb.	12.00	—	14.00
Vanadium Ore, per lb. of V ₂ O ₅ contained	lb.	1.25	—	—
Zircon, washed, iron free	lb.	.10	—	—

*Nominal

Non-Ferrous Metals

New York Markets

	Cents per lb.
Copper, electrolytic	19.00
Aluminum, 98 to 99 per cent	33.00
Antimony, wholesale lots, Chinese and Japanese	7.50
Nickel, ordinary (Ingots)	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	48.50
Lead, New York, spot	9.50
Lead, E. St. Louis, spot	8.90
Zinc, spot, New York	8.35
Zinc, spot, E. St. Louis	7.90 to 8.40

OTHER METALS

Silver (Commercial)	on	\$80.99
Cadmium	lb.	1.40 to 1.50
Bismuth (500 lb. lots)	lb.	2.70
Cobalt	lb.	3.00
Magnesium (f.o.b. Niagara Falls)	lb.	1.75
Platinum	on	115.00 to 120.00

Palladium	on	100.00 to 110.00
Mercury	75 lb.	83.00

FINISHED METAL PRODUCTS

Warehouse Prices

	Cents per lb.
Copper sheets, hot rolled	33.50
Copper bottoms	38.00
Copper rods	38.00 to 40.00
High brass wire and sheets	30.25
High brass rods	27.00
Low brass wire and sheets	28.50
Low brass rods	29.00
Brass tubing	36.25
Brass bronze tubing	41.75
Seamless copper tubing	34.00
Seamless high brass tubing	33.00

SCRAP METALS

Cents per lb.

	Buying Price
Aluminum, cast scrap	23.00 to 23.50
Aluminum, sheet scrap	23.00 to 23.50
Copper, heavy machinery comp.	14.50 to 15.00
Copper, heavy and wire	15.25 to 15.75
Copper, light and bottoms	13.00
Copper, heavy cut and crucible	16.25
Brass, heavy	10.25
Brass, light	7.75 to 8.00
No. 1 clean brass turnings	9.00 to 9.50
No. 1 comp. turnings	12.50 to 13.50
Lead, ton	4.75 to 5.00
Lead, heavy	7.25 to 7.50
Zinc, scrap	5.25

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by 1/4 in. and larger, and plates 1/4 in. and heavier, from jobbers' warehouses in the cities named:

	New York	Cleveland	Chicago
	Current	Month Ago	Year Ago
Structural shapes	\$4.47	\$3.97	\$3.47
Soft steel bars	4.47	4.12	3.37
Soft steel bar shapes	4.47	4.12	3.37
Soft steel bands	6.32	5.32	4.07
Plate, 1/4 to 1 in. thick	4.67	4.17	3.67

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

MARTINEZ—The Petroleum Products Co., San Francisco, is building a lubricating oil refinery near here. Estimated cost, \$100,000.

Colorado

DENVER—The Federal Glass Co., c/o Sylvester & Co., First Natl. Bank Bldg., recently incorporated, plans to build a plant, including office bldg., circular glass house, factory and gas plant. Estimated cost, \$250,000.

HAIXTON—The city council will soon award the contract for the construction of a sanitary sewer system, including a septic tank. Estimated cost, \$65,000. Royal D. Salisbury, 1415 E. Colfax Ave., Denver, engr.

ROCKY FORD—The American Beet Sugar Co. plans to build a 3-story building. Laboratory equipment will be installed in same. Estimated cost, \$50,000.

YUMA—The city council will soon award the contract for the construction of a sanitary sewerage system, including a septic tank. Estimated cost, \$80,000. Royal D. Salisbury, 1415 E. Colfax Ave., Denver, engr.

Connecticut

NEW HAVEN—Yale University is having sketches prepared for the construction of a 2-story chemical laboratory. Estimated cost, \$250,000. Delano & Aldrich, 126 East 38th St., New York City, archts.

PORTLAND—The Portland Foundry Co., Freestone St., has awarded the contract for the construction of a 2-story 40x50-ft. foundry addition to Thos. Sellaw. Estimated cost, \$50,000.

Illinois

MARVA—The city plans to construct a sewage disposal plant. Estimated cost, \$83,000. Miller, Holbrook & Waner, Milliken Bldg., Decatur, engr.

Indiana

ONWARD—The Bd. of Educ. has awarded the contract for the construction of a 2-story, 80x125-ft. high school to S. I. Barnes, Logansport, \$95,000. A chemical laboratory will be installed in same.

Maryland

BALTIMORE—The Amer. Can Co., 120 Bway., New York City, is having plans prepared for the construction of a factory. Estimated cost, \$500,000.

BALTIMORE—The Coca-Cola Co., Pratt St. and Market Pl., has awarded the contract for the construction of a 4-story 196 x531-ft. factory and cooperage plant on Port Ave. to the Arthur Tufts Co., Candler Annex, Atlanta, Ga. Estimated cost, \$1,250,000.

CURTIS RAY (Baltimore P. O.)—The Union Acids Works plan to extend their plant. A 250x520-ft. site has been purchased on Aspen St. near Curtis Ave.

Massachusetts

BROCKTON—The city plans to build filtration bed. Estimated cost, \$150,000.

Michigan

DETROIT—The Detroit Lacer Co., 27 A St., has awarded the contract for the construction of a 1-story, 80x100-ft. heat-treating building on A St. to the Scotten & Katz Building Co. Estimated cost, \$35,000. Noted May 4.

GRAND RAPIDS—The city is having plans prepared for the construction of an

additional waterworks system, including an addition to the filtration plant, etc. C. A. Paige, City Hall, engr.

WEST DETROIT (Detroit P. O.)—Varney & Varney, archts., Washington Blvd., Detroit, plan to build a 1-story, 70x90-ft. foundry. Estimated cost, \$20,000. Owner's name withheld.

Minnesota

BERMIDJI—The Bd. of Educ. plans to build a 3-story high school. Chemical laboratory will be installed in same. Estimated cost, \$500,000.

FVLEETH—The city plans to install a filter plant. Estimated cost, \$50,000.

WARASSO—G. A. Goblirsch, village clk., will receive bids until Sept. 9 for the construction of a sewage treatment plant and disposal plant. Estimated cost, \$45,000. John F. Druar, 512 Globe Bldg., St. Paul, engr.

Missouri

ST. LOUIS—The city is having plans prepared for the construction of a mortue. Chemical laboratory and operating rooms will be installed. Estimated cost, \$68,000. L. R. Bowen, City Hall, archt. and engr.

ST. LOUIS—The Sisters of Charity, 3539 Pine Blvd., are having preliminary plans prepared for the construction of a hospital on Pine St. Chemical laboratory will be installed in same. Estimated cost, \$2,000,000. Lee & Rush, Syndicate Trust Bldg., archts.

ST. LOUIS—The Temtor Corn and Fruit Products Co. is constructing a building on Michigan Ave. and Davis St. Estimated cost, \$200,000.

New York

BROOKLYN—Henry Holder, 242 Franklin Ave., will soon award the contract for the construction of a 1-story, 100x250-ft. foundry on Columbia St., for J. Riley. Estimated cost, \$250,000.

Ohio

AKRON—The city has awarded the contract for the construction of 10 filtration beds, capacity 20,000,000 gal., to the Garrett Constr. Co., Kent. Estimated cost, \$313,624.

BEDEFORD—The David Round & Son Co. has awarded the contract for the construction of a 1-story 90x180-ft. foundry addition to the DuPerow Const. Co., Plymouth Bldg., Cleveland. Estimated cost, \$50,000.

CINCINNATI—Rendigs, Panzer and Martin, archts., Palace Theatre Bldg., will receive bids about Sept. 15 for the construction of a 1-story pottery to have 45,000 sq. ft. of floor space on Lester Rd. for the Wheatley Pottery Co., Reading Rd.

CLEVELAND—The Rickersberg Brass Co., 3612 Perkins Ave., is building a 1-story 11x24-ft. foundry addition. Estimated cost, \$5,000.

CLEVELAND—Western Reserve University, c/o E. Spense, Dean, plans to build a 3-story pharmacy building on Adelbert Rd. and Euclid Ave. Estimated cost, \$200,000.

PAINEVILLE—The Light Alloys Co. has awarded the contract for the construction of a 1-story 75x140 ft. factory to the H. K. Ferguson Co., 6532 Euclid Ave., Cleveland. Estimated cost, \$65,000.

Oklahoma

FAIRFAX—The city plans to construct sewage disposal plant and waterworks extensions. Estimated cost, \$80,000. V. V. Long & Co., 1300 Concord Bldg., Okla. City, consult. engr.

HENRYETTA—The Cogswell Refining Co. is having plans prepared for the construction of a petroleum refinery, having a capacity of 2,000 bbls. Estimated cost, \$25,000. J. C. Bertsch, Tulsa, engr.

Pennsylvania

NEW CASTLE—The Lehigh Portland Cement Co., 718 Hamilton St., Allentown, had plans prepared for the construction of a plant. Estimated cost, \$200,000.

PHILADELPHIA—The Hellwig Silk Dyeing Co., 9th and Buttonwood Sts., has awarded the contract for the construction of a 2-story 95x235-ft. factory on Holme-stead and Milnor Sts., to F. W. Van Loon, Perry Bldg. Estimated cost, \$90,000.

PITTSBURGH—The Pittsburgh Forge & Iron Co., Chamber of Commerce Bldg., is receiving bids for the construction of a 2-story, 18x22 and 35x88-ft. coal mill building. Estimated cost, \$40,000. Fuller Engr. Co., Allentown, engr.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1920 convention and exhibit at Columbus, Ohio, the week of Oct. 4.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS is holding its one hundred and twenty-second meeting Aug. 20 to Sept. 3, on Lake Superior.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PEAT SOCIETY will hold its annual meeting at Madison, Wis., Sept. 2, 3 and 4, 1920.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1920 annual meeting will be held in the Engineering Societies' Building, from Dec. 7 to 10 inclusive.

AMERICAN STEEL TRADERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS will hold its 14th annual convention at the Hotel Pennsylvania, New York City, Sept. 20 to 24, 1920.

THE CHEMICAL WARFARE POST of the American Legion will hold its next meeting Sept. 22, at 8 p.m., in the conference room of the Grand Central Palace, New York City.

ELECTRIC FURNACE ASSOCIATION will hold a meeting Oct. 6, at Columbus, Ohio, the subject of which will be "Refractorics."

ENGINEERING COUNCIL will hold its next meeting in Chicago Thursday, Oct. 21, 1920.

INSTITUTE OF METALS DIVISION of the A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SIXTH) will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12, 1920.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Putting Our Industries On a Scientific Basis

IT IS neither possible nor advisable to characterize each issue of a technical magazine by a special selection or arrangement of its editorial contents. But occasionally there is advantage in selecting a broad theme and building around it as complete a structure as possible. Accordingly in this issue of CHEMICAL & METALLURGICAL ENGINEERING we have adopted an editorial plan to which all else is subordinated.

We have always preached the doctrine of applying scientific methods to industrial processes, believing that therein lies our hope of industrial independence and supremacy. This was brought home in the most forcible manner during the war, and since then the rapid adoption of science by industry has been one of the most hopeful elements in our industrial development. And yet much remains to be done to put our industries on a scientific basis. It was with this in mind that we conceived the idea of inviting forward-looking leaders in a group of industries to forecast the scientific developments and applications which must be made if industry is to prosper and flourish in the highest degree. The hearty response to our invitation indicated the extent to which men in all branches of industry are thinking along this line. Some of the contributors to this issue have been delightfully frank, acknowledging the shortcomings of their respective industries and pointing the way to the researches and developments that should be made. In fact we were deprived of the privilege of publishing one article because its author showed a state of affairs so distasteful and uncomplimentary to his principals that they requested him to withdraw the article.

Sugar production is one of our principal industries and in his article on this subject Mr. DAHLBERG shows the possibility of building a byproduct chemical industry on factory refuse. This line of investigation is now engaging the attention of one of our largest beet-sugar companies. The problems of the petroleum industry as forecast by Mr. HAMOR consist principally in a better utilization of present supplies by varying the products of distillation to meet the changing demand. "Cracking," or pyrolysis as Mr. HAMOR more aptly calls it, is still a fertile field for investigation. Dr. WASHBURN shows us clearly in his article that the progress of technology is dependent on the interpretation and application of existing physicochemical knowledge; and this is supplemented by Dr. RICHARDS in his plea for "more and better tools" with which to work. The influence which science is bringing to bear on the treatment of sewage and trade waste is removing much of the obnoxious element in past processes and making possible the handling of these materials without offense. Mr. BAILEY writes instructively of the vegetable-oil industry,

which is assuming such vast proportions. Future problems are concerned with the production of crude oils and fats, their refining and the finished products. Research is indicated in methods of solvent-extraction instead of pressing. In the rubber industry we are informed that better physical tests are needed for the guidance of manufacturers, and it appears that future developments will be along physical rather than chemical lines. Mr. STEVENS shows that the great problem of the pulp and paper industry is fuel conservation, the improved design of mechanical equipment and the adoption of vacuum driers. Dr. BANCROFT writes entertainingly on his favorite subject of applied colloid chemistry and illustrates its relation to some practical problems.

The leather industry, according to Mr. WILSON, is greatly in need of fundamental theoretical knowledge, and he feels that the greatest good can be accomplished for his industry through co-operation between university and tannery chemists, the former bringing their fundamental knowledge to bear on the practical work of the latter. The glass industry, we are informed by Dr. TILLOTSON, is indebted for its present position and prospective progress to the application of mechanical engineering in the use of automatic machinery. In the hardwood distillation industry there is much the same need as is evidenced in the petroleum industry for ability to control the nature of the products in accordance with the industrial demand for them. Mr. HAWLEY also discusses the prospect of altering the products of distillation by introducing chemicals into the kiln with the wood. In the paint and varnish industry Mr. TOCH points out the necessity of studying possibilities of blending materials which themselves may be inferior but which in combination may produce a superior product. New pigments also form an attractive field for research. In his article on alloys Dr. FINK reveals an almost unlimited field for research in the production of unusual alloys to meet the ever growing demands of special service. Mr. TUNISON has traced the influence of science on the manufacture of industrial alcohol, illustrating the progress in still and rectifier design. A large field for research remains in the development of byproducts. The future of the animal products industry, according to Mr. RICHARDSON, will be centered primarily in byproducts—the aim of the industry being to convert as much as possible of the material into food. The byproducts range from glue to enzymes. Artificial leather and coated fabrics are destined to play an important industrial role, and the article on that subject will be of general interest.

Of more than ordinary interest is the article on the necessity for research in the oil-shale industry. Mr. GAVIN speaks for the Bureau of Mines, which is conducting investigations of a fundamental character both as to the technology of shale oil and the best type of retort. It is quite evident that science will have an

opportunity to contribute largely to the establishment of this industry. In suggesting experiment with the Scotch retort Mr. GAVIN takes a stand in opposition to other authorities, but his line of reasoning involves building a new industry on past experience. Low-temperature carbonization of coal presents a number of problems which are discussed by Dr. CURTIS. The byproducts from this treatment, consisting of mixtures of paraffine and coal-tar bodies, present problems which will require scientific knowledge for their solution.

This wide range of industries would have been still further expanded by appropriate articles on the future rôle of chemistry in food production, fertilizer manufacture and ceramics had the authors not been unavoidably delayed in their work. These articles we hope to present in subsequent issues. The omission from this issue of the market reports, price lists and other miscellaneous items is caused by the large number of contributions and the necessity for conserving paper.

Chemical Warfare Post Of the American Legion

ONE of the important meetings to be held during the week of the Chemical Exposition will be that of the Chemical Warfare Post of the American Legion. On the evening of Sept. 22 in the Conference Room of the Grand Central Palace it is planned to effect a permanent organization, membership being open to all C. W. S. ex-service men. The new Post should be vigorously supported by those who are eligible to membership, not only for purposes of sociability but for the perpetuation of traditions of the service and assistance to General FRIES and his organization.

The Origin of Signs and Symbols

IT WAS EDMONDO DE AMICIS, we believe, who said that at Constantinople ten thousand people tread the bridge across the Golden Horn every day, but that an idea crosses it only once in ten years. And we wonder how often in our modern affairs we bring ideas from the past over the bridge of scholarship?

If we look into the history of chemistry we find it clearly divided into periods of progress. We cannot well go back of THALES of Miletus (about 640-550 B.C.), who was rather a mathematician than a chemist, although from him we have the postulate that water is the source of all things. He lived on an island, he is said to have been a business man, and it was he who introduced *abstract* geometry, the object of which is to establish precise relations between the different parts of a figure. It seems, however, beyond doubt that in the eighth century B.C. there were astronomical observatories in most of the cities of the Valley of the Euphrates, so that there was great learning and study before his day. The only trouble is that we have lost the threads of it. Plane geometry THALES is said to have learned from Egyptian priests. ANAXIMENES and LEUCIPPUS were a bit younger, but were contemporaries of THALES and also citizens of Miletus. They proposed air and earth as the substantial elements. HERACLITUS of Ephesus came a little later (540-475 B.C.) but was probably born before ANAXIMENES and LEUCIPPUS died, and he maintained that fire was the primordial thing. Before him it was PROTHAGORAS (660-583 B.C.), who followed still earlier philosophers, antedating even the Chaldeans, from whom ABRAHAM sprang, in regard to

the supremacy of fire. It was of these pre-Chaldean teachers that a profound scholar now dead told the writer many years ago that they had left this record: "We worship GOD, and GOD only. We hold the sun to be His symbol, because from it come both light and heat; moreover, in it are contained all the elements of the earth."

EMPEDOCLES (490-430 B.C.) proposed earth, air, fire and water as the four elements of matter, and DEMOCRITUS of about the same time originated the atomic theory. Water, he said, was liquid, because its atoms are smooth and round and can easily glide one over another. A solid like iron, he contended, must be made up of atoms which are hard and rough. ARISTOTLE (384-322 B.C.) made the distinction between what he called the matter and the essence of a substance. If it had not been for the ecclesiastical commentators on ARISTOTLE, who claimed supernatural control of that which is intangible, we might have concluded that he foreshadowed chemical energy and latent heat and that he foretold radioactivity. But even if he did he probably didn't know it. ARISTOTLE also noted that wine yielded an inflammable substance.

ARCHIMEDES (289-212 B.C.) and ERATOSTHENES (276-194 B.C.) addressed themselves rather to hydrostatics and mechanics, and there followed PLINY the Elder (23-79 A.D.), who enjoyed the friendship of emperors and was a delightful old gossip, writing down everything he could read or learn. His Natural History is a joy to this day, even if it is grotesquely wrong in almost every respect. It is beautifully translated, and we know of no more fascinating book for the idle hours of a man of science. Then darkness was upon the earth.

The next glimpse of light seems to have been reflected originally from Egypt, but brought into Europe along about the eighth century by the Arabs. They had the idea of a *materia prima*, present in all things, but always contaminated by impurities. By many processes of purification, especially by fire, it was hoped to obtain the true "essence" or "tincture," and this was substantially the philosopher's stone which could work miracles. But our pious forbears would have none of this ungodly thinking. The learned Arabs were put to death whenever this was possible, because they were unbelievers, and therefore in league with SATAN. Their books were burned. The only idea that was acceptable was the plan to get rich quick by turning baser metals into silver and gold, and this also was under lively suspicion of daemonic origin. It continued through mediæval and renaissance days, and some of the alchemistic symbols were designed to represent the planets supposed to be associated with various metals. Others were empirical marks made to hide the meaning of the writers lest they be held guilty of the high crime of Inorthodoxy.

Alchemy developed into iatrochemistry, or medical mysticism, which began with PARACELSUS, who was born in 1493, and the symbols were still in use when America was discovered. They were not always the same; many were invented and used by individuals as cipher, but an interesting number of them have come down to us. We have used a few for the cover of this issue, from which we modestly think it may be observed that they lend themselves especially to decorative purposes. The meanings of those shown on our cover, beginning at the upper left-hand corner and reading to the right are: Gold, earth, silver, copper, vitriol, sulphur, salt, air, water, fire, mercury, lead, tin and iron.

Cleanliness

In the Plant

A CONTRIBUTOR to FRANKLIN P. ADAMS' "Conning Tower" column of the New York *Tribune* writes as follows: ". . . As I see more and more of benighted Japan I recall with an involuntary shudder a journey through Kansas last spring—Kansas, the richest community on earth, with a bleak environment of derelict outbuildings, faded 'homes' of bald and hideous architecture, lawns conspicuous by infrequency, and right-angled white schoolhouses. I wonder what strange psychology prompts the Japanese peasant, crowded and illiterate, . . . to build him a picturesque little cottage, as neat inside as a new cigar box, surrounded by shrubbery and a priceless garden. And I wonder what instinct prompts the wife to array herself in classically artistic fashion, and to attire her offspring in like manner. In Kansas the stranger closes his eyes; in Japan he rarely encounters anything to affront them."

We do not know why the author selected Kansas for his comparison; there are plenty of other states that would have served equally well. But his point is well taken; we Americans are very low in the scale of artistic conscience. We are practical in a utilitarian sense, but we are among the least practical of peoples in æsthetics. In our own field of industry we probably rank below the farmer in this respect. Chemical works are notoriously ugly, and ugliness of structure and surroundings is one of the principal enemies to cleanliness, to order, to comfort in living, and to the pleasant things of life. Hygienic equipment and baths are excellent in their way, but they do not go all the way. If we learn that a chemical factory is to be built in the neighborhood where we live, we are usually disposed to move away if we can; we fear that it will stink; and we have good reason to believe that it will have a dirty, messy entrance and neglected grounds about it.

We know that, inside the works, cleanliness and not only convenient but pleasant arrangements are worth while. The outside we regard as not important, and here we are wrong. The outside *is* important. Every man and woman that works for us is impressed by appearances as he or she enters our portals. It is not necessary that these be conscious impressions. Psychology and experience both teach us that it is the persistent repetition of impressions that counts large in determining the direction of our thoughts and the mold of our opinions. The worst billboard offenders know this, and make it the very basis of their offenses. For instance, if some enterprising tobacconist plasters the walls and fences of the town with advice to smoke his Mercaptano cigars, we may not be disposed to smoke them, but all unconsciously we find ourselves asking for a couple of Mercaptanos when we step in at the cigar store to buy a smoke.

The stranger that passes by registers an impression of us, whether he knows it or not, if only he casts a glance at our works. This impression is either that as a corporate entity we are ugly and dirty and that we stink, or that we look well and agreeable and pleasant. In order that the latter rather than the former opinion be registered as to our persons, most of us bathe diligently, shave every day, wear clean linen, have our boots polished and do what we can to produce what we call a "good" impression. We may say we don't care what people think, but usually in our hearts we know this is

not so. So long as we are beyond the pinch of poverty, even shabby clothes are more likely than not to be a studied carelessness to give the impression of affability with all sorts and conditions of men.

If, then, we would have our persons create an agreeable impression, there is abundant reason why our works should do likewise. True, a proper care for and pride in the exterior of our plant increase the overhead charges, and overhead charges are not popular, especially if they can be avoided. But overhead charges are as necessary as fuel or a sales department. A vast amount of administrative wisdom lies in discrimination as to overhead. Old Uncle DAN'L DOLLARDODDLE, who doesn't know or care for anything but dividends, wants to cut out all "deadwood," as he calls it, as soon as he comes on the board of directors and begins to debilitate the company. He condemns the library, the research laboratory, the testing plant and the gravel walks and sod. He condemns everything on which he does not see a crop of immediate dividends growing. And usually he ruins the business. We recognize the presence of infinitely minute quantities of certain bodies which we cannot analyze, and yet which make or mar our products by their presence. Now, there are intangible qualities that also hold good in regard to the outside of the works. The effect of beauty or ugliness is silent but persistent. In what we do we represent the application of science which, for the welfare of all, we need to introduce into life. History, it is claimed, must be rewritten in the light of science, in the light of man's conquest of nature, rather than according to the might, the battles and the whimsies of kings. The day is dawning when the opinion of men of science is asked in regard to public affairs, and science, like other vocations, is known by its works. The factory is properly called the works. Men of science have a greater public responsibility today than ever before. So far as industrial chemists are concerned, how do their works appear? In the great majority of cases they look like the devil.

Radioactivity as the

Possible Cause of Heartbeat

RELATED information from Holland reveals researches which Professor ZWAARDEMAKER has been making into the physiological effects of radioactivity. In some highly interesting experiments with solutions of radioactive metals on isolated frog hearts previously brought to a standstill with potassium-free Ringer's solution, the ingenious professor has coaxed the vital organs into renewed pulsations. Perfusion with solution of radioactive elements in proper dosage restored the heartbeat, whereas none of the non-radioactive elements did so. Dr. ZWAARDEMAKER also discovered that the absence of radioactive element in the kidney allows the passage of sugar and throws the muscular wall of the arterioles out of action, while normal activity is restored by the addition of a radioactive element.

Somehow we cannot help regretting that the eminent doctor made his discoveries. Life is becoming so complex that there seems to be no rest for the weary. After, as has been the habit of some of us, talking so much and saying so little about vitamins, both water-soluble and fat-soluble, must we now begin to worry about our radioactive rations? Must those of us who may be of diabetic propensity now prepare to take a mesothorium cure?

Program of the Exposition

Symposia Prepared by the Exposition Management on Fuel Economy, Industrial Management, Materials Handling, Chemical Engineering, and Ceramics—Motion Pictures Illustrating a Wide Range of Industrial Chemical Operations

FOLLOWING is the program of the Sixth National Exposition of Chemical Industries, to be held at the Grand Central Palace, New York City, Sept. 20 to 25:

Monday, Sept. 20

8 P.M.

Opening address by Charles H. Herty.

"Co-operation in the Industries," Charles L. Reese.

Sir George E. Foster, Canadian Minister of Trade and Commerce, will speak.

"Problems Confronting the American Exporter," Erastus Hopkins (Gaston, Williams & Wigmore, Inc.).

Followed by motion pictures:

1. "The U. S. Ammonium Nitrate Plant No. 2 at Muscle Shoals." (2 reels.) (Courtesy Dwight P. Robinson & Co.)

2. "Modern Packaging Methods." (4 reels.) (Courtesy Pneumatic Scale Corporation.)

Tuesday, Sept. 21

2 P.M.—FUEL ECONOMY SYMPOSIUM

Chairman's Address, R. C. Beadle (Managing Editor, *Combustion*).

"Burning Coal at 100 Per Cent B.t.u. Efficiency," W. O. Rankin (Quigley Furnace Specialties Co.).

"Saving Fuel by Controlling Chimney Losses," F. F. Uehling (Uehling Instrument Co.).

"Fluid Heat Transmission," Alexander B. McKechnie (Parks-Cramer Co.).

"Producer Gas and the Modern Mechanical Producer," W. B. Chapman (Chapman Engineering Co.).

"Refractory Cement: Life Insurance for a Furnace," F. W. Reisman (Quigley Furnace Specialties Co.).

"Preventing Conduction and Radiation Heat Waste," S. L. Barnes (Armstrong Cork Co.).

"Increasing Conduction and Reducing Fuel Consumption," W. R. Van Nortwick (The Roto Co.).

"The Reason for the Fuel Saving in the Dressler Kiln," Conrad Dressler (American Dressler Tunnel Kilns, Inc.).

8 P.M. MOTION PICTURES

Great U. S. chemical industries:

1. "The Story of Sulphuric Acid." (1 reel.) (Courtesy General Chemical Co.)

2. "The Production of Salt for the Chemical Industry." (1 reel.) (Courtesy International Salt Co.)

3. "Perfumes for the World." (Courtesy Antoine Chris Co.)

4. "A New Chemical Industry: Leather From the Ocean: Fish Leather." (3 reels.) (Courtesy Ocean Leather Co. and Ford Educational Film Co.)

Wednesday, Sept. 22

2 P.M.—INDUSTRIAL MANAGEMENT SYMPOSIUM

"Ultra Analysis of Costs," Harrington Emerson (The Emerson Engineers).

"Research in Industrial Conservation," H. E. Howe (Chairman, Division of Research Extension, National Research Council).

"Progress of the American Coal-Tar Industry," Grinnell Jones (U. S. Tariff Commission).

3 P.M.—MATERIALS HANDLING SYMPOSIUM

Chairman's Address, Roy V. Wright (Editor, "Material Handling Cyclopedia").

"Material Handling: The Paramount Problem," J. H. Leonard (Editor, "Freight and Terminal Engineering").

"Chain Power Transmission," F. G. Anderson (Morse Chain Co.).

"Steel Collapsible Shipping Containers as Related to the Chemical Industries," Everett W. Morgan (Pneumatic Scale Corporation).

8 P.M.

Meeting of Chemical Warfare Post.

(Speakers to be announced.)

Thursday, Sept. 23

2 P.M.—CHEMICAL ENGINEERING SYMPOSIUM

(Meeting of the American Institute of Chemical Engineers, David Wesson, Chairman.)

"A New Method of Destructive Distillation," Thomas W. Pritchard (Fuel Products Corporation).

"Nitration of Hydrocarbons," A. Hough and W. Savage.

"Recoverance: A Physical Property in Material and Its Importance," Robert G. Guthrie (Widney Test Laboratories).

"Operating Data of a Modern Byproduct Coke Oven Plant," C. R. Bellamy.

"Canada and the Chemist," C. Price-Green (Canadian National Railways).

"Utilization of Peat" (illustrated), B. F. Haanel (Canada Department of Mines).

"Corrosion of Iron and Steel as Affecting the Industries," W. D. Richardson (Swift & Co.).

6:30 P.M.

Dinner of American Institute of Chemical Engineers at the Technology Club.

8 P.M.—MOTION PICTURES

Great U. S. chemical industries:

1. "Modern Coke and Gas Manufacture." (3 reels.) (Courtesy The Koppers Co.)

2. "The Story of Petroleum Oil." (3 reels.) (Courtesy Standard Oil Co. of New Jersey.)

3. "The Asphalt Paving Industry." (1 reel.) (Courtesy Barber Asphalt Paving Co.)

4. "Colloidal Movement in Asphalt." (1 reel.) (Courtesy Barber Asphalt Paving Co.)

Friday, Sept. 24

2 P.M.—CERAMIC SYMPOSIUM

(Meeting of the American Ceramic Society, R. H. Minton, Chairman.)

"The Meaning Attached to the Term 'Ceramics' in Ancient and Modern Usage." Committee Report, Condensed.

"A Classification of Sheet Steel Enamels," R. R. Danielson, (U. S. Bureau of Standards.)

8 P.M.—MOTION PICTURES

Mining industries:

1. "The Story of Coal." (4 reels.) (Courtesy Sullivan Machinery Co. and U. S. Bureau of Mines.)

2. "Building, Mining and Quarrying Machinery." (2 reels.) (Courtesy Sullivan Machinery Co.)

3. "Producing Pumps and Engines." (1 reel.) (Courtesy Midwest Engine Co.)

4. "Silver Mining in Ontario." (1 reel.)

5. "Gold Mining in Ontario." (1 reel.) (Courtesy Ontario Department of Mines).

6. "The Manufacture of Pottery." (1 reel.) (Courtesy American Ceramic Society).

Saturday, Sept. 25 •

2 P.M.

• Speakers to be announced.

8 P.M.—MOTION PICTURES

1. "Manufacture of Asbestos." (1 reel.)

2. "Silks and Satins." (2 reels.) (Both by Courtesy Bureau of Commercial Economics.)

3. "Foamite Firefoam Extinguishing Apparatus at Work." (1 reel.) (Courtesy Foamite Firefoam Co.)

4. "Continuous Motion, Conveying, Stacking, Elevating, Loading and Unloading Machinery." (1 reel.) (Courtesy Brown Portable Machinery Co.)

5. "The U. S. Ammonium Nitrate Plant No. 2 at Muscle Shoals, Alabama." (2 reels.) (Courtesy Westinghouse-Church-Kerr, Inc.)

Exhibitors at the Exposition

A Brief Description of the Exhibits of Over Four Hundred Exhibitors Prepared for the Exposition Visitor Who Wishes to Conserve His Time and Make Certain of Seeing Those Things in Which He Is Most Interested

THE following societies and publications have reserved booths for reception and social purposes where they will be glad to receive their friends.

AMERICAN CHEMICAL SOCIETY.
AMERICAN DYESTUFF REPORTER.
AMERICAN DYES INSTITUTE.
AMERICAN ELECTROCHEMICAL SOCIETY.
AMERICAN FERTILIZER.
CANADIAN CHEMICAL JOURNAL.
CANADIAN MINING JOURNAL.
CANADIAN TEXTILE JOURNAL.
CHEMICAL AGE.
CHEMICAL & METALLURGICAL ENGINEERING.
CHEMICAL CATALOG.
CHEMICAL COLOR AND OIL DAILY.
COLOR TRADE JOURNAL.
COMBUSTION.
CONTAINER CLUB.
IRON AND STEEL OF CANADA.
JOURNAL OF COMMERCE.
JOURNAL OF INDUSTRIAL AND ENGINEERING CHEMISTRY.
MANUFACTURERS RECORD
OIL, PAINT AND DRUG REPORTER.
PAPER MILL AND WOOD PULP NEWS.
PULP AND PAPER MAGAZINE OF CANADA.
TEXTILE COLORIST.
TEXTILE WORLD JOURNAL.
TEXTILES.

The following list of exhibitors at the Sixth National Exposition of Chemical Industries, together with a brief statement of their exhibits and names of representatives, will be of special value to those who expect to attend the Exposition. Being published well in advance, it will enable prospective visitors to conserve their time and give attention to those matters in which they are particularly interested. The list is practically complete. Where no description of exhibit is given, the information requested either was not furnished or

arrived too late for publication. No attempt has been made to give booth numbers or location in the Grand Central Palace, because these will be more easily obtained from the handbook and guide which will be distributed at the Exposition with our compliments.

ABBE ENGINEERING Co.—Ball mills, pebble mills, laboratory grinding machines, disintegrators, rotary cutters for roots, herbs, rubber, etc.; bolting cloth. In charge of exhibit: H. F. Kleinfeldt.

ABBE, PAUL O., INC.

AINSWORTH, WM., & SONS.—Precision analytical and assay balances; precision analytical balance with keyboard-operated weight carrier for handling fractional gram weights. Precision assay balance with a sensitivity of 1/1000 mg.; readings are indicated by a reflected beam of light. In charge of exhibit: Robert G. Ainsworth.

AJAX ELECTROTHERMIC CORP.—Laboratory induction furnace with vacuum tube; brass tube annealing furnace; brass-melting furnace for materials of melting point not above 1,550 deg. C. In charge of exhibit: Edwin F. Northrup, Dudley Willcox and Harry F. Porter.

ALBERENE STONE Co.—Exhibit of laboratory construction of Alberene stone, consisting of a typical fume hood, wall table with reagent shelves, sink, peg-board, etc. In charge of exhibit: E. L. Collins, W. K. Fields, R. G. Grothe, W. Heins, A. Y. Mecker and N. N. Moneypenny, Jr.

ALCOHOL PRODUCTS CO.

ALEXANDER, W. H.

ALLEN ELECTROLYTIC CELL CORP.—The Allen-Moore electrolytic cell. In charge of exhibit: Kent R. Fox and Howard D. Marsh.

ALLIS-CHALMERS MANUFACTURING CO., INC.—Dust collector, motors, rubber-lined centrifugal pump, pulverator. In charge of exhibit: Representatives from the New York office.

AMERICAN ANILINE PRODUCTS, INC.—Full line of colors dyed on felt, leather, wool, cotton and silk. Line of essential oils and fine chemicals. In charge of exhibit: Messrs. Fenton, Gossen, Roelofs, Mehnen, Bennefield, Giroward, Collins, Chase, O'Hara, Hennessy, Whyte, Gregor, McDermott, Schleicher and Cheesman.

AMERICAN CHEMICAL & MFG. CO.

AMERICAN CHEMICAL & SUGAR MACHINERY CO.—Patent multiplex film evaporator and McLaurin patent gas scrubber. In charge of exhibit: Messrs. Lawrence and Duglinson.

AMERICAN CYANAMID CO.—Illuminated wall case showing models of the principal apparatus used in the fixation of atmospheric nitrogen, and the intermediate and finished products of the cyanamide process. In charge of exhibit: E. J. Franke, R. R. Stewart and J. P. Hubbell.

AMERICAN DRESSLER TUNNEL KILNS—Illuminated screen showing continuous view of tunnel kilns and their application to chemical processes; samples of materials such as bricks, porcelain, steel, and malleable iron which have been treated in tunnel kilns. In charge of exhibit: Conrad Dressler.

AMERICAN HARD RUBBER CO. Hard rubber equipment for handling acids, alkalis, dyes, food products and corrosive chemical solutions. A hard rubber pump will be shown in operation. In charge of exhibit: A. M. Ackerman.

AMERICAN KRON SCALE CO.—Automatic dial scales. In charge of exhibit: John J. Kelly.

AMERICAN LAFRANCE FIRE ENGINE CO., INC.—Industrial safety devices, fire prevention apparatus, chemical engines and fire extinguishers. In charge of exhibit: H. J. Lovell and James W. Knoblock.

AMERICAN METAL CO., LTD.—Ores and products of zinc, molybdenum, lead, copper, gold, silver, arsenic, selenium; sulphuric acid. In charge of exhibit: H. M. Burkey, E. K. Judd, R. C. Latz and Miss A. M. Stout.

AMERICAN METAL PRODUCTS CO.—Acid-resisting castings and finished parts such as valves and cocks; shafting, sheet, rods. Souvenirs will be presented to purchasing agents and engineers, consisting of chisels of 84 per cent copper with which steel may be chipped. In charge of exhibit: R. W. Alger and C. J. Zaiser.

AMERICAN PULVERIZER CO.—American pulverizers suitable for the chemical industry. In charge of exhibit: Dunning, Luckel Engineering Co.

AMERICAN ROLLING MILL CO.

AMERICAN STEEL & WIRE CO.—Sulphate of iron, both sugar and crystal form; different materials made from sulphate of iron or in which this plays an important part in manufacture. In charge of exhibit: Arthur S. Latz.

AMERICAN TRANSFORMER CO.**AMERICAN WATER SOFTENER CO.**

ANACONDA COPPER MINING CO.—Products and byproducts from the smelting and refining of copper ores; electrolytic zinc; uses of copper in the chemical industry illustrated by equipment loaned for the occasion; Anaconda white lead. In charge of exhibit: S. Skowronski.

ANACONDA LEAD PRODUCTS CO.**ANACONDA ROLLING MILL DEPT.**

ANGEL, H. REEVE, & CO.—Filter paper of American manufacture; rubber tubing, glass wool, etc. In charge of exhibit: B. S. Proper and T. L. Harrocks.

ANILINE DYES & CHEMICALS, INC.**ANILINE SALES CORP.****ANTHRACONE DYE PRODUCTS & CHEMICAL CO.**

ANTI-HYDRO WATERPROOFING CO.—Liquid chemical compound for rendering concrete waterproof, dustless, oil-proof, acid resisting and chemical resisting. In charge of exhibit: B. A. Meyer, Thomas Moore, Joseph Meyer, M. R. Duffy, M. E. Townsend, Charles A. Brown.

APEX CHEMICAL CO.—Antimony sulphide and other antimony compounds; sulphonating oils, softening, finishing compounds, etc., for the textile industry; chemical specialties for the leather industry; fabrics and leather which have been treated by these specialties.

ARKELL SAFETY BAG CO.—Complete line of "Arksafe" elastic paper linings for shipping packages, plain and waterproofed. In charge of exhibit: Pedro J. Morales.

ARMSTRONG CORK CO.—Nonpareil insulating brick for furnaces, boiler settings, kilns and other high temperature equipment; Nonpareil high-pressure insulation for steam lines, and other hot surfaces; Nonpareil cork covering for brine and ammonia lines and other cold surfaces; Nonpareil corkboard for cold storage rooms or wherever constant temperature is required. In charge of exhibit: Representatives from New York office.

ARNOLD, HOFFMAN & CO., INC.—Oils, softeners, gums, starches, pigment and other colors for textile sizing, printing, and finishing, and for use in the paper, chemical, leather and other industries. In charge of exhibit: H. H. Hall, C. L. Berntson, E. M. DeBaun, G. D. Curtis, H. P. Geier.

ATERITE CO., INC.—Aterite-trimmed valves and cocks for handling petroleum; Aterite valves, cocks and fittings for

high temperature stills and sulphuric acid lines; also valves and fittings for all temperatures of steam, both saturated and superheated. Wrought Aterite in the shape of rods, sheets, wire, etc. In charge of exhibit: Ernest G. Jarvis.

ATLANTIC DYE-STUFF CO.—The central feature will be a miniature dye-making plant, in addition to which the company will show its various products. In charge of exhibit: Charles H. Stone, G. R. Stoettner, H. M. Paine, H. K. Ullrich, C. C. Burt and Karl Ruger.

ATLAS ELECTRIC DEVICES CO.—Color Fade-ometers for color testing by standardized radiation. In charge of exhibit: Clarence W. Jameson and Hugh E. Weightman.

BABBITT, B. T.

BACHARACH INDUSTRIAL INSTRUMENT CO.—Pressure recorders and gas meters in actual operation; special demonstration showing the application of Pitot tube to the measurement of gases. In charge of exhibit: Herman H. Sticht, Mr. Lauterbach, and Mr. Bacharach.

BACHMEIER & CO.—Aniline dyes. In charge of exhibit: G. M. Lord, William Baur and H. L. Gettler.

BAILEY METER CO.—Working exhibit of meters for water, steam, gases, and various chemicals. In charge of exhibit: E. G. Bailey, W. R. Little, H. M. Hammond, N. Dmytrow, Jr. and M. Repa.

BAKER, J. G., CHEMICAL CO.

BARBER ASPHALT PAVING CO.—Comprehensive exhibit of native lake asphalts and their products, with special reference to those useful in chemical plants and laboratories. Crude and refined asphalt, mineral rubber, ready roofing, asphalt shingles, preservative paints, high-grade oils for special lubricating purposes, flotation oils.

BARRETT CO., THE—This company has joined forces with the General Chemical Co., the National Aniline & Chemical Co., the Smet-Solvay Co. and the Solvay Process Co. in a series of booths containing an instructive and educational exhibit of their products. In charge of exhibit: H. G. Sidebottom.

BAUSCH & LOMB OPTICAL CO.—Metallographic equipment, consisting of large photomicrographic camera with special microscope designed for metallographic work; optical measuring instruments such as the Duboseq colorimeter, Abbe & Dipping refractometer and saccharimeter, chemical microscope and binocular microscope. In charge of exhibit: E. H. Anthes, I. L. Nixon and W. L. Patterson.

BEACH-RUSS CO.—The following machines will be shown in operation: High-duty vacuum pumps, rotary air compressors, laboratory pumps, acid pumps and heavy liquid pumps. In charge of exhibit: Howard C. Russ.

BEAVER CHEMICAL CO.—Sulphur colors. In charge of exhibit: John E. Rooney and John B. Dunbar.

BECKER, CHRISTIAN, INC.—Analytical and laboratory balances, featuring the chainomatic balances; bullion scales; torsion balances. In charge of exhibit: W. C. Symington, A. T. Millroy and J. W. Wetz.

BECKLEY PERFORATING CO.

BETHLEHEM FOUNDRY & MACHINE CO.—Wide range of castings of Corrosiron. Demonstration by acid test of a comparison of the wearing qualities of Corrosiron against cast iron. In charge of exhibit: J. George Lehman, R. E. Wilbur, A. H. Stevens, R. H. Stevens and George Ettele.

BLACKMER ROTARY PUMP CO.—Models of pumps, with necessary explanatory charts and pictures of the various units made. In charge of exhibit: A. L. Rock and F. P. Goertz.

BLACKSTON'S SON, P., & CO.

BOOTH ELECTRIC FURNACE CO.—Booth rotating brass furnace of 500-lb. capacity. In charge of exhibit: C. H. Booth, E. F. Tweedy and F. W. Doran.

BOYER OIL CO., INC.—Vegetable oils such as castor, coconut, cotton, mustard, palm, rape and sunflower, together with the seeds from which they are made and typical by-products. In charge of exhibit: Messrs. Boyer, Kienle, Blythe, Weber and others.

BRISTOL CO.—Full line of recording and indicating instruments for pressure and vacuum, liquid level, temperature, electricity, time, motion, speed. In charge of exhibit: H. L. Griggs.

BROWN INSTRUMENT CO.—Comprehensive display of indicative and recording pyrometers, recording and resistance thermometers, indicating and recording instruments for pressure, vacuum, speed, time and operation. In charge of exhibit: J. D. Andrews, M. A. Leister, George W. Goodman, R. B. McCafferty, C. D. Porterfield and O. W. Stowe.

BROWN PORTABLE CONVEYING MACHINERY CO.—Portable inclined elevator for piling boxes, bags and bales. Portable inclined elevator for loading and elevating loose material. Hand power portable tiering machine for lifting and piling cases, rolls and drums. In charge of exhibit: O. H. Oertel

BUCKMAN & PRITCHARD, INC.—Exhibit of refractory shapes, bricks, cupola blocks and crucible high tension insulators and spark plug cores of zirconium silicate or zircon. Commercial products of ilmenite and rutile, including a newly developed white pigment. In charge of exhibit: George A. Pritchard and H. H. Buckman.

BUFFALO FOUNDRY & MACHINE CO.—Vacuum drying apparatus, evaporators, chemical equipment and sugar apparatus. New developments during the past year in Bufflovak and Bufflokast apparatus. In charge of exhibit: E. G. Rippel.

BURRELL TECHNICAL SUPPLY CO., INC.—Burrell gas analysis apparatus and other testing apparatus. In charge of exhibit: G. H. Burrell, R. P. Mase and H. J. Segrave.

CALCO CHEMICAL CO.—Dyes and intermediates with demonstration of dyeings on fabrics, paper pulps and lakes. In charge of exhibit: Messrs. Sampson, Sumner, Klein, Bosworth, Ackerman, Paradies and Merry.

CALIFORNIA ALKALI CO.

CANADA CARBIDE CO.

CANADIAN ELECTRODE CO.

CANADIAN ELECTRO PRODUCTS CO., LTD.—Carbide of calcium, acetic acid, acetaldehyde, paraldehyde, U. S. P. and commercial and aldehyde ammonia. In charge of exhibit: H. E. Mussett, Henry Booth and J. C. Fruit.

CANADIAN PACIFIC RAILWAY CO.

CARBORUNDUM CO.—Crude carborundum and aloxite crystals; silicon metal; carborundum and aloxite abrasive products, such as grain, abrasive paper, cloth and wheels; carborundum refractory brick and special shapes; silfrax pyrometer protection tubes and muffles. In charge of exhibit: Otis Hutchins, Dr. Hartman, S. C. Linbarger, C. E. Hawks and W. L. Meek.

CARRIER ENGINEERING CORP.—Complete installation of Carrier humidifying equipment in operation, and typical products into the manufacture of which Carrier equipment enters. In charge of exhibit: J. E. Bolling.

CELLULOID ZAPON CO.

CENTRAL SCIENTIFIC CO.—Constant temperature apparatus consisting of electrically heated and controlled drying ovens, vacuum ovens and water baths; high vacuum pumps; electrically operated laboratory devices; electric furnaces and electro-titration apparatus; oil and fuel testing equipment; physicochemical apparatus. In charge of exhibit: S. L. Redman, O. T. Lewis and A. B. Carter.

CHADWICK-BOSTON LEAD CO.

CHAPMAN ENGINEERING CO.—Automatic floating agitator complete with automatic feed in actual operation. Regulating and recording devices in actual operation on pressure and vacuum lines. In charge of exhibit: W. B. Chapman.

CHAPMAN VALVE MFG. CO.

CHEMICAL CO. OF AMERICA, INC.—Dyes and intermediates. In charge of exhibit: S. Iserman, Chas. Kendall, A. P. Christ, R. H. Steele and F. X. Lehmann.

CHEMICAL EQUIPMENT CO.—Ceco products, comprising acid valves and pumps, priming systems, spray systems, experimental vacuum evaporator. All except the latter will be in operation. In charge of exhibit: H. E. LaBour, R. T. White, F. L. Dunlap and E. M. Baker.

CHEMICAL PUMP & VALVE CO.—Centrifugal pumps, packingless valves and fittings for chemical works. In charge of exhibit: A. B. Antisell, F. A. Warner.

CHRIS, ANTOINE, CO.—Full line of essential oils, synthetic aromatic chemicals, resins, oleo resins, etc.; manufactured in American factories. Also a full line of products from the company's French factories; capes-viscose, a self-fixing bottle capping.

CLEVELAND-CLIFFS IRON CO.—Refined wood chemical products; methyl alcohol, methyl acetone, acetone, acetic acid, hexamethylenamine, etc. In charge of exhibit: Charles B. Hall, Austin Farrell and E. J. Hudson.

CLEVELAND INSTRUMENT CO.—Thermo-electric and resistance types of indicating and recording pyrometers; multiple station circular chart recorder. In charge of exhibit: Herman H. Sticht, W. B. North and H. B. Rich.

CLINCHFIELD PRODUCTS CORP.—Feldspar, ground and crude; variety of finished articles using this material. In charge of exhibit: Charles Ingram and Leo L. Hunt.

CLIPPER BELT LACER CO.—Three different types of clipper belt lacing machines; demonstration of belt lacing. In charge of exhibit: William F. Kall.

COMMERCIAL SOLVENTS CORP.

CONSOLIDATED CHEMICAL PRODUCTS CO.

CONTACT PROCESS CO.—Sulphuric, muriatic and nitric acids, fuming sulphuric acid, oleum, mixed acid, salt cake. In charge of exhibit: Dr. von Rucker and T. Smith.

CORNING GLASS WORKS.—Complete line of Pyrex laboratory glassware and apparatus. In charge of exhibit: G.

Willis Drake, Frederick Kraissl, Irving B. Cary, F. F. Pfeiffer and A. S. Eggleston.

CRANE CO.

CRANE PACKING CO.—Full line of "John Crane" flexible metallic packings for liquid, vapor and acid service. Demonstration of electrolytic disintegration of tubes and pipes, with methods of packing to avoid this destruction. In charge of exhibit: Julian N. Walton and F. E. Payne.

CRESCENT SALES & ENGINEERING CO.—Crescent roto-piston vacuum and pressure pumps, Crescent vacuum chucks. In charge of exhibit: L. L. Becken.

DAVIDSON, M. T., Co.—Steam pumps for general power plant service and for acid. In charge of exhibit: John Lowe and William E. Brennan.

DAVISON CHEMICAL CO.—Pyrites ore, cinders, sinter, copper precipitate, sulphuric acid, acid phosphate, double superphosphate, magnesium fluosilicate, precipitated silica and silica gel. A working exhibit showing the absorbent qualities of silica gel. In charge of exhibit: E. B. Miller, B. F. Lovelace, Walter A. Patrick, W. D. Huntington, J. R. Wilson and A. E. Marshall.

DELAVAL SEPARATOR CO.

DENVER ENGINEERING WORKS CO.

DERMATOLOGICAL LABS.

DETROIT ELECTRIC FURNACE CO.—Detroit electric furnaces for melting brass, bronze, copper, aluminum, cast iron and steel alloys. In charge of exhibit: E. L. Crosby, E. L. Kavanaugh, H. M. St. John and A. E. Rhoads.

DETROIT RANGE BOILER & STEEL BARREL CO.—"Perfect" metal bilge barrels, black and galvanized; Detroit drums both light and heavy type with removable head. In charge of exhibit: W. B. Goddard, C. C. Choate, H. Ross Mack.

DEVINE, J. P., Co.—Display of vacuum apparatus, such as drum driers, chamber driers and vacuum pumps; also an exhibit of "Kek" pulverizing mills. In charge of exhibit: J. P. Devine, C. P. Devine, L. W. Graves, E. H. Miller and H. C. Mills.

DIAMOND STATE FIBER CO.—Vulcanized fiber in sheets, rods, tubes, cans, sample cases, trunks; condensite celoron waterproofing insulation. In charge of exhibit: Charles M. Bogert.

DINGS MAGNETIC SEPARATOR CO.—Three magnetic separators in operation for the treatment of material which may be submitted. In charge of exhibit: J. R. Manegold, E. S. Hirschberg, J. E. Randall, S. G. Oates and A. H. Ackerman.

DOMINION WATER POWER BRANCH OF THE DEPARTMENT OF THE INTERIOR OF OTTAWA, CANADA.—This bureau will be in charge of engineers qualified to give general and particular information concerning Canada's water-power and economic minerals, both of which are important in the establishment and development of the chemical industry in Canada. In charge of exhibit: J. B. Challies, J. P. Johnston and A. M. Beale.

DORR CO., THE.—Working installation of Dorr agitator, tray thickener and pump demonstrating methods of mixing and dewatering applicable to chemical and industrial processes; small working models of Dorr equipment. The special feature will be a miniature sewage treatment plant. In charge of exhibit: P. M. Mclugh, H. N. Spicer and H. W. Morgan.

DOW CHEMICAL CO.—Chemicals: pharmaceutical, industrial, heavy; dyes; intermediates; insecticides. In charge of exhibit: G. Lee Camp, Leland I. Doan, Ralph E. Dorland, George Ashworth and Wilson I. Doan.

DRACKETT, P. W., & SONS CO.

DRAFTER MFG. CO.

DRYING SYSTEMS, INC.—Small drier for the chemical industry. In charge of exhibit: F. A. Lippert, C. H. Currier and R. E. Lippert.

DUNNING, LUECKEL ENGINEERING CO.—Nelson wood plate and frame filter press for corrosive liquids. American ring pulverizer for pulverizing lime stone, pyrite, salt, phosphate rock, etc. In charge of exhibit: Harry Dunning, W. J. Lueckel and Paul S. Knittle.

DU PONT DE NEMOURS, E. I., & Co.—This company will exhibit products of the following divisions: Lithopone, dry colors and pigments division, chemical products division, acids and heavy chemical division and dyestuffs sales division. Special attention will be given to the display of dyes.

DURIRON CASTINGS CO.—Comprehensive selection of Duriron apparatus, covering standardized designs of regular equipment and new equipment. First showing of the industrial film "The Story of Duriron." In charge of exhibit: Messrs. Schenck, Pitman, Hall, Dart, Pratt, Smith, Daniels, Elkins, Suverkrop, Jaffe, Schatzabel, H. H. Van Eten and O. Jacobsen.

EAGLE PITCHER LEAD CO.—Display of lead products, and products of other industries in which lead is used; a model of a sublimed white lead (basic sulphate) plant. In charge of exhibit: H. Gates, A. F. Brown, C. E. Gilson, L. E. Kelly and J. R. MacGregor.

EAST JERSEY PIPE CO.—The centrifugal and extractor department will exhibit a Hercules-Electric hydro extractor and a 7-in. working model machine of the same design. In charge of exhibit: H. H. Stephens.

EASTMAN KODAK CO.—Organic chemicals for research purposes; Eastman tested chemicals for photographic use; exhibits of a physical and photographic nature from the research laboratory.

ECONOMIC MACHINERY CO.

ECONOMY ENGINEERING CO.—Miniature oil warehouse containing economy steel barrel racks and tiering machines; full-size electrically driven tiering machines; full size hand power tiering machines; one unit economy steel barrel rack, full size. In charge of exhibit: T. R. Tordoff.

EDGAR BROS. CO.

EGYPTIAN LACQUER MANUFACTURING CO.—Lacquers, thinners, enamels and similar products, as well as finished articles on which these products have been used. In charge of exhibit: Messrs. Sopher, DeBaun, Popper, Hayward, Henry and Schlott.

EIMER & AMEND.—Replaceable unit electric furnaces and hot plates; Freas electric ovens; Hortvet cryoscope; Juerst ebullioscope; Bingham & Green viscometer and plastometer; McMichael viscosimeter; U. S. Navy type emulsifier; Barnstead water still; Wysor polishing and grinding apparatus; Braun pulverizer; Morgan drop weight apparatus; American rotary vacuum pump; MacLeod gage, Columbia University type; Kobe condenser; Fleming and Fisher combustion bulbs; Hortvet butter fat bottle; refractometers; microscopes and Duboseq colorimeters. In charge of exhibit: C. G. Amend, W. R. Eimer, F. Wilbur Schulenberg, Theodore Taistra, I. Banner and Herman Weber.

ELECTRIC FURNACE CO.

ELECTRO BLEACHING GAS CO.—Finished products which have required the use of liquid chlorine in the process of their manufacture. In charge of exhibit: James B. Dugan, S. W. Jacobs, S. I. Escocet, W. A. Kennedy and George R. Ellis.

ELECTROLYTIC ZINC CO., INC.

ELECTRON CHEMICAL CO.—Allen-Moore electrolytic cell. In charge of exhibit: Kent R. Fox and Howard D. Marsh.

ELMORE, G. H.—Elmore continuous centrifugal machine in operation. In charge of exhibit: G. H. Elmore and R. W. Rigler.

ELYRIA ENAMELED PRODUCTS CO.—Elyria enameled stills, autoclaves, open-jacketed tilting kettle complete with agitator, still complete with condenser, receiver and pump. The autoclave and the multiple unit condenser, which will be shown with the 10-gal. still, are entirely new developments. In charge of exhibit: Wm. E. Gray, Wm. E. Gray, Jr., Max Donauer and R. W. Smith.

EMPIRE LABORATORY SUPPLY CO., INC.—Chemical glassware and apparatus; laboratory supplies of all kinds. In charge of exhibit: M. A. Goldstein, E. C. Weiskopf, H. L. Thompson, J. C. Headley, P. Freedman and H. Freedman.

ENGELHARD, CHARLES.—Indicating and recording pyrometers, automatic temperature regulators, electric furnaces, impervite refractories, pyrometer tubes, transparent quartz glass, electric resistance thermometers, mercury vapor arc lamps. In charge of exhibit: C. W. Hubbard.

EVERLASTING VALVE CO.

EXCELSIOR DYESTUFFS & CHEMICAL CO.—Dyes and chemicals. In charge of exhibit: Walter Reinicke and Charles Frankel.

FALCON DYE & CHEMICAL CO., INC.—Aniline colors. In charge of exhibit: Dr. E. C. Altwater, Harry Laut and Julius Oettinger.

FLEISHER, W. L., & CO., INC.—Air-conditioning apparatus and a spray drier. In charge of exhibit: W. L. Fleisher, A. W. Lissauer and D. L. Connelly.

FLORASYNTH LABORATORIES.—Raw materials for flavoring extracts, flavoring extracts and other aromatic chemicals; betanaphthol benzoate and benzyl benzoate medicinal. In charge of exhibit: Louis A. Rosett, Charles L. Senior and Alexander Katz.

FOAMITE FIREFOAM CO.—Fire extinguishers of the smaller type using foamite and firefoam, with demonstration of the effectiveness of these extinguishers in smothering fire. In charge of exhibit: R. H. Austin.

FOOTE MINERAL CO.—Display of rare and unusual ores, together with chemical products manufactured from the

same. A feature of the exhibit will be the demonstration of the refractory properties of zirkite and zirkonalba in the electric furnace. In charge of exhibit: H. C. Meyer and Samuel K. Bell.

FOXBORO CO., INC.—Recording and indicating instruments for pressure and vacuum, hydraulic gages, combinations of recording thermometer and temperature controller. CO. recorder in operation, and other instruments. In charge of exhibit: W. W. Patrick and E. P. Grout.

FUEL PRODUCTS CORP.

GARRIGUE, CHAS. F., CO.

GARRIGUE, WILLIAM, & CO.—Oils, fats, glycerine and soaps in various stages of processing. In charge of exhibit: J. W. Bodman, O. H. Wurster and W. E. Sanger.

GEIGY CO., INC.

GENERAL BAKELITE CO.—Bakelite materials with examples of their various applications; operation of molding press giving demonstration of the bakelite molding process. In charge of exhibit: Hylton Swan, H. S. May, L. M. Rossi, C. H. Hall and William S. Gordon, Jr.

GENERAL BRIQUETTING CO.—Briquets made from fine fuels and fine chemical and metallurgical byproducts. In charge of exhibit: A. L. Stillman, J. Sprung and J. E. Stevens.

GENERAL CERAMICS CO.—Models of standard chemical stoneware apparatus consisting of a complete plant for the manufacture of muriatic acid which will be operated at intervals during the exposition; chemical stoneware exhaust fan and an etching machine which will be operated as required; fused silica shapes made at the company's new plant near Perth Amboy, N. J. In charge of exhibit: Percy C. Kingsbury, F. A. Whitaker and R. S. Beecher, A. C. Otto, Hubert Royer and K. J. Peters.

GENERAL CHEMICAL CO.—Working model of the latest type sulphuric acid tank car; 5-ton model of the new Herreshoff for roasting ores, in operation daily; display of reagent chemicals. In charge of exhibit: Messrs. A. W. Hawkes, G. G. Ackerson, C. K. Shean, George N. Vardy, J. H. Eberhardy, M. M. Biddison, J. E. Wilson, R. P. Silva, W. J. Kramer and J. L. Thomas.

GENERAL ELECTRIC CO.

GENERAL FILTRATION CO., INC.—Filters uniformly porous, acid-proof, artificial stone, filter plates in various shapes and sizes; Filters acid-proof cement, and acid-proof stoneware girders. In charge of exhibit: F. E. Leiby and W. W. Robacher.

GENERAL FIRE EXTINGUISHER CO.

GEORGIA LEAD WORKS.

GIBSON PRICE & CO.

GLAMORGAN PIPE & FOUNDRY CO.—Working model of continuous gas-fired limekiln and standard flaking and congealing machine; nine compartment filters and standard Duplex exhauster. In charge of exhibit: C. H. Hinnant.

GLASS COATING CO.

GLENS FALLS MACHINE WORKS.—Demonstration of rotary sulphur furnace for production of SO₂; model of a Knot & Silver screen for use on either chemical or mechanical wood pulp. In charge of exhibit: Harold D. Wells and Fred S. Chaffee.

GORDON DRYER CORP.—Gordon high-efficiency atmospheric-type drier for drying chemicals, colors, dyestuffs, pharmaceutical and medicinal products. In charge of exhibit: Nathan Owitz, N. W. Park and John Bogge.

GOTTESMAN, M., & CO., INC.—Industrial chemicals for the paper and pulp industry, such as sulphate of soda, sulphate of alumina, bleaching powder, china clay, casein, rosin, blanc fixe and soda ash. In charge of exhibit: Arthur J. Sigel, Guy A. Gardner and E. A. Pita.

GOULDS MANUFACTURING CO.—Line of pumping machinery suitable for use in chemical plants. In charge of exhibit: W. H. Hopper, H. R. Gumbert, W. H. Valentine, W. J. O'Neill, H. J. Angell and E. E. Brereton.

GREELEY PRODUCTS CORP.—Lubricating, vegetable, fish and animal oils, pine products and industrial chemicals. In charge of exhibit: H. A. Carman, H. S. Kenyon, W. R. Boin and B. D. McCampbell.

GREINER, EMIL, CO.—Chemical and scientific instruments and apparatus made of glass. In charge of exhibit: Emil Greiner, Emil Vonhof, P. Todtschinder and M. Kohn.

GRINNELL CO., INC.—Grinnell automatic sprinkler and other Grinnell fire-protection devices. The Grinnell automatic sprinkler will be shown in operation periodically throughout the exposition. In charge of exhibit: Howard E. Branch, Frank V. Sackett, F. S. Crans, Henry Walsh and Robert Nicholson.

GROCH CENTRIFUGAL FLOTATION, LTD.

GRUENDLER PATENT CRUSHER & PULVERIZER CO.

GUERNSEYWARE Co.—Complete line of chemical laboratory porcelains consisting of crucibles, casseroles, evaporating dishes, beakers, combustion boats, mortars and pestles, porous cells, etc. In charge of exhibit: Allan L. Goulding.

HAMILTON & HANSELL, INC.—Illustrations of electric-furnace installations. Information on general metallurgical processes such as ore dressing, smelting, chloridizing and leaching processes in accordance with the Ramen patents. Models of flue cleaners. In charge of exhibit: H. A. De Fries.

HANOVIA CHEMICAL & MANUFACTURING Co.—Electric resistance furnaces, quartz resistance thermometers, Hanovia quartz mercury arc lamp, transparent quartz laboratory ware and Engelhard pyrometers. In charge of exhibit: A. L. Schweickart, E. Simonds, G. H. Wilson, Leon Witmond, R. W. Newcomb and C. W. Hubbard.

HARDINGE Co.—Hardinge conical ball and pebble mills for metallurgical, chemical and industrial crushing and grinding, either wet or dry. In charge of exhibit: W. H. Baker, R. B. T. Killiani, Harlowe Harding, James G. Parmelee, G. F. Metz and S. R. Swain.

HAUSER-STANDER TANK Co.—Tank of red gulf cypress lined with chemical lead with joints burnt in by hand; vacuum filter tank of long leaf yellow pine; methods of construction of wooden tanks. In charge of exhibit: S. Hauser, Jr. and D. B. Dorfan.

HAYNES STELLITE Co.

HAYS, JOSEPH W., CORP.

HAYWARD, S. F., & Co.

HEPWORTH, S. S., Co.—Mackintosh electrically-driven centrifugal in operation. In charge of exhibit: C. A. Olcott, E. Foster Babbitt and George Fred Brindley.

HERCULES ENGINEERING CORP.

HERCULES POWDER Co.—Dummy explosives, soluble cotton wet with water and soluble cotton solutions; naval stores. In charge of exhibit: W. M. Annette and G. C. O'Brien.

HEROLD CHINA & POTTERY Co.—Complete line of chemical and scientific porcelain ware. In charge of exhibit: H. F. Coors.

HEYL LABS, INC.

HEYDEN CHEM. Co OF AMERICA

HOOKE ELECTROCHEMICAL Co.

HOSKINS MANUFACTURING Co.—Electric laboratory and tool furnaces, indicating and recording pyrometers and chromel heat-resistant castings. In charge of exhibit: W. D. Little, Charles S. Kinnison, F. L. Zimmerman, A. L. Malmstrom and J. E. Hines.

HOYT METAL Co.

HUFF ELECTROSTATIC SEPARATOR Co.—Operating exhibit of the Huff electrostatic separator and Olumb pneumatic jig. A special feature of the exhibit will be the separation of ash and sulphur from coal.

HUNTER DRY KILN Co.

HUYCK, F. C., & SONS—Woolen filter cloth. In charge of exhibit: D. A. MacInnes, E. A. Rees and A. V. Wright.

HYDROCARBON CHEMICAL Co.

IDEAL STENCIL MACHINE Co.

IMPERIAL DYEWOOD CORP.

INDEPENDENT CHEM. Co.

INDUSTRIAL ELECTRIC FURNACE Co.—New type of electric melting furnace for operation on a 220-volt d.c. motor circuit. In charge of exhibit: F. von Schlegel, W. B. Cooley, L. C. H. Groeger and W. B. Lewis.

INDUSTRIAL FILTRATION CORP.—Zenith continuous rotary filter, Zenith continuous rotary hopper dewaterer and Zenith open-tank type filter. The Zenith rotary filter will be in operation in connection with a complete filtration unit for this type of apparatus. In charge of exhibit: William H. Harding, G. D. Dickey, H. W. Conrad and A. W. Wright.

INNIS SPEIDEN & Co, INC.

INTERNATIONAL CARBON PRODUCTS Co.—Graphite and graphite products which have been electrically refined by the Huff electrostatic process.

INTERNATIONAL COOPERAGE Co.

INTERNATIONAL NICKEL Co.—Monel metal, natural nickel alloy, resisting alkalis, most acids, superheated steam, high temperatures and corrosion. In charge of exhibit: E. S. Wheeler, T. H. Dauchy and F. H. Waycott.

INTERNATIONAL SALT Co. OF NEW YORK—Salt in all grades. In charge of exhibit: H. J. Osborn.

IRVING IRON WORKS Co.—Irving-subway metallic flooring and safetop. In charge of exhibit: W. E. Irving, P. L. Price, H. H. Schuldt, A. S. Kennedy and W. H. Lown.

JEWELL POLAR Co.—Water-distilling apparatus, operated by steam, gas and electricity. In charge of exhibit: A. C. Jewell, J. E. Bloeser and P. M. Marks.

JOPLIN WHITING Co.

KALBFLEISCH CORPORATION—General line of mineral acids, some of the allied salts and products particularly interesting to paper manufacturers. In charge of exhibit: A. C. Kalbfleisch, V. P. Davis and C. L. Hutzelman.

KENART SYNTHETIC PRODUCTS Co.

KEWAUNEE MFG. Co.

KING CHEMICAL Co.

KLIPSTEIN, A., & Co.

KNIGHT, MAURICE A.—Acid-proof chemical stoneware apparatus, selected to convey a good idea of the use of this material in chemical industry. In charge of exhibit: Maurice A. Knight, Charles Dennison, Samuel J. Baril and Newton D. Whipple.

KNOXVILLE BOARD OF COMMERCE—Natural raw materials in vicinity of Knoxville, suitable for use in electrochemical and electrometallurgical industries. In charge of exhibit: Harry Clark, John A. Switzer, Walter McIntyre, H. A. Morgan, M. F. Nichols, Charles A. Weller, J. N. Newman and W. R. Pouder.

KOPPERS Co.—Sectional model of Koppers triangular-flued combination coke and gas ovens; photographs of byproduct coke and gas plants. In charge of exhibit: E. L. Crowe and C. R. Meissner.

LAKEWOOD ENGINEERING Co.

LAMIE CHEMICAL Co, INC.—Dyes and chemicals. The feature of the exhibit will be Flaming Red, a new dyestuff used in the paper and silk industry. In charge of exhibit: K. E. Schlossing.

LAMMERT & MANN Co—Lammert rotary vacuum pumps, for vacuum or pressure. In charge of exhibit: A. L. Eisenbics, Donald Rosie and R. F. Lammert.

LAUREL SOAP MANUFACTURING Co.—Textile soaps, sizing and finishing material.

LEAD LINED IRON PIPE Co.—Galvanized lead-lined iron pipe, flanged lead-lined valves and fittings, screwed lead-lined fittings, tin-lined iron pipe and fittings. In charge of exhibit: Daniel H. Regan and Frank H. DuBois.

LEEDS & NORTHRUP Co—Electrical measuring instruments for chemical and metallurgical processes. Features of the exhibit will be: equipment for demonstrating the Hump method for heat treatment of steel; optical and thermocouple pyrometers, including equipment for automatic recording, signaling and control; outfit for electro-metric determination of hydrogen ion concentrations; recording and controlling Wheatstone bridge for electrolytic conductivity work; automatic recording and controlling potentiometer for regulating amount of reagent added in an acid-alkaline reaction. Most of the exhibits will be in actual operation. In charge of exhibit: Paul E. Klopsteg, A. M. Redding, I. M. Stein, R. D. Milner, George W. Tall, Jr., G. H. English and E. B. Estabrook.

LIBERTY BY-PRODUCTS WORKS, INC.—Compounds of antimony and chromium; lactolin, soaps and oils. In charge of exhibit: E. A. F. Zillesen, E. J. Zillesen, W. H. Zillesen, August Naab, Jr., A. Washington and P. B. Meerbott.

LINDSAY LIGHT Co.—Display of salts of the rare earths. In charge of exhibit: Dr. McCoy, A. Sinai and Otto N. Berndt.

LIQUID CARBONIC Co.

LUOMIS-MANNING FILTER DISTRIBUTING Co.—Standard filters and a filter in section showing interior construction and details; glass working model showing operation. In charge of exhibit: George H. Powell.

LUNG MOTOR Co.—The Lungmotor for resuscitation in cases of apparent drowning, asphyxiation, electric shock, narcotic poisoning, strangulation and collapse during anaesthesia. In charge of exhibit: L. D. Jones and Max Jacobsen.

LUNKENHEIMER Co.—Valves in bronze, iron and cast steel suitable for various operating conditions and for pressures up to 350 lb. per sq.in. and a temperature of 800 deg.; engineering specialties.

LUZERNE RUBBER Co.—Hard rubber pipe, fittings, buckets, and special parts for the chemical industry. In charge of exhibit: H. E. Case.

MAAS & WALDSTEIN Co.—Wood and metal work showing applications of clear lacquer and lacquer enamel finishes; lacquer and lacquer enamels in glass containers. In charge of exhibit: Harry C. Flannigan.

MAGNESIA ASSOCIATION OF AMERICA—Samples of different kinds of 85 per cent magnesia; diagrammatic chart showing

manufacture in process; miniature samples of 85 per cent magnesia products. In charge of exhibit: C. J. Stover, G. S. Stuart.

MAGNETIC MANUFACTURING CO.—Demonstration of a laboratory-size high-intensity magnetic separator for such ores and minerals as may be offered for treatment. In charge of exhibit: J. P. Bethke.

MANN & COOK.

MATHIESON ALKALI WORKS, INC.—Caustic soda, soda ash, Virginia soda, bicarbonate of soda, bleaching powder, liquid chlorine, chlorine solvents; materials produced from these products. In charge of exhibit: John A. Kienle, John W. Boyer and G. N. Davis.

MEAD & CO.—Mead mills, featuring a laboratory mill. In charge of exhibit: Paul O. Abbe.

MERCK & CO.—Medicinal chemicals and blue label reagent chemicals.

MERRILL CO.—Merco Nordstrom plug valve. In charge of exhibit: C. C. Broadwater, L. D. Mills, F. H. Ricker, H. P. MacGregor and S. J. Nordstrom.

METALS DISINTEGRATING CO., INC.—Zinc dust, lead dust, tin dust, copper dust, litharge. In charge of exhibit: S. G. Schatzberg.

MIDLAND CHEMICAL CO.

MIDWEST ENGINE CO.—In charge of exhibit: F. L. Atwood, D. I. Smith, R. C. Palmer, G. A. Drysdale.

MINE & SMELTER SUPPLY CO.—Wilfley concentrating table, Ruth flotation machine, Dourte valveless pump in operation; Samson laboratory jaw crusher, McCool pulverizer, Heusser balances. In charge of exhibit: E. S. Tompkins and J. C. Beam.

MINER-EDGAR CO.—Cotton solutions for coating split and artificial leathers; solvents for cotton and celluloid; wood alcohol, acetone, methyl acetone; prepared clays for paper and paint manufacturers. In charge of exhibit: Rolland H. French, J. J. Smith, Charles H. Zeiger, George N. Bick, John W. Johnson.

MINE SAFETY APPLIANCE CO.

MINERAL POINT ZINC CO.

MOBILE & OHIO RAILROAD CO.

MOJONNIER BROS. CO.

MONARCH MANUFACTURING WORKS, INC.—Brass, iron, hard rubber and stoneware sprays, for use in sulphuric acid manufacturing plants; lead valves; lead siphons; oil burners, and an automatic acid elevator, which when attached to existing acid eggs elevates acid to any desired height automatically.

MONEL METAL PRODUCTS CORP.—In booth with International Nickel Co., showing monel metal. In charge of exhibit: H. F. Chase and H. A. Cooper.

MONO CORP. OF AMERICA.—Automatic recording instruments for analyzing CO₂, CO, SO₂; recorder for oxygen and hydrogen. In charge of exhibit: F. D. Harger and Olaf Rodhe.

MORSE CHAIN CO.—Samples of chains, showing the Morse rocker joint, from $\frac{1}{2}$ in. pitch to 3 in. pitch and in several widths illustrating the chain as used for $\frac{1}{2}$ hp. to 5,000 hp. In charge of exhibit: T. G. Anderson, H. W. Evans, A. B. Wray, V. D. Morse, J. S. White, E. R. Morse and H. M. Rodda.

MOTT, J. L., IRON WORKS.

MULTI METAL CO., INC.—New U. S. standard sieve series; wire cloth screens and filter cloth in unusual weaves, meshes and metals. In charge of exhibit: Siegfried Stern, Frederick Stern, Selmar Pullman and Louis Dresner.

NASH ENGINEERING CO.—Hytor compressors and vacuum pumps in operation; Jennings pump, motor and turbine driven, for handling combinations of liquid and gas. In charge of exhibit: Irving C. Jennings, H. M. Wylie and G. B. Wright.

NASSAU VALVE & PUMP CORP.—Chemetal acid-resisting valve and centrifugal pumps. In charge of exhibit: A. T. Haviland, E. J. Walsh, H. C. Evans and C. Schmitt.

NATIONAL ANILINE & CHEMICAL CO.—Scene of wax figures costumed in the latest modes and artistically grouped on the piazza of a country house. All the materials used in this scene will be dyed with the "National" colors. The central setting will be flanked on either side by exhibits of the company's technical products.

NATIONAL BINDING MACHINE CO.

NATIONAL FILTER CLOTH & WEAVING CO.

NATIONAL GUM & MICA CO.—Pulp and other colors; permasol marking ink, crayons, etc.; synthetic perfume bases; adhesives. In charge of exhibit: Messrs. Alexandre, Namy, Harris, Adrizonne and N. A. McManus.

NATIONAL LAMP WORKS.

NELSON, ALFRED W.

NEWARK WIRE CLOTH CO.—Wire and wire cloth, chemists' testing screens, monel metal filter cloth; loom for weaving in operation. In charge of exhibit: A. A. Campbell and E. C. Nichols.

NEW ENGLAND TANK & TOWER CO.

NEW JERSEY ZINC CO.—Flow sheet showing developing of zinc ore into finished products; display of zinc products and descriptive literature. In charge of exhibit: W. Homer Hendricks and S. T. Ballinger.

NEWPORT CHEMICAL WORKS, INC.

N. Y. COLOR & CHEMICAL CO.—Dyes and colors for the textile, paper, leather and lake trades. In charge of exhibit: Messrs. Williams, Jacquith, Taylor, Carter, Richmond, Staneck and Wardlaw.

NEW YORK CONTAINER CO., INC.

NIAGARA ALKALI CO.—Caustic potash, caustic soda, bleach powder, permanganate of potash and muriatic acid.

NIAGARA ELECTRO CHEMICAL CO.

NICHOLS COPPER CO.

NITROGEN PRODUCTS CORP.—In charge of exhibit: J. C. Clancy and A. Nagelvoort.

NITRO PRODUCTS CO.—H acid. In charge of exhibit: W. H. Van Winkel and H. D. Wellmann.

NORTHWESTERN CHEMICAL CO.—Organic esters, salts and acids; synthetic flavoring materials. In charge of exhibit: Robert L. Wilson and Henry J. Beck.

NORTON CO.—Representative shapes of laboratory ware and larger refractories made from alundum and crystallon; grinding wheels and abrasive grain; electrically fused magnesia. In charge of exhibit: C. W. Saxe and R. Kirkpatrick.

OBERMAYER, S., CO.—Hott-Patch furnace cement for power and chemical plants. A small electric furnace will be used for demonstration of the product. In charge of exhibit: E. D. Frohman, John L. Cummings, H. E. Beckman and J. M. Hildebrand.

OLIVER CONTINUOUS FILTER CO.—A small size Oliver continuous filter in operation. In charge of exhibit: R. G. Walker, H. A. Morrison, P. M. Depp and W. A. V. Thomsen.

ONTARIO DEPARTMENT OF MINES.—Representative ores and minerals from the province of Ontario, with special attention to gold, silver and nickel-copper. Smelter and refinery products will also be shown. In charge of exhibit: W. K. McNeill and W. R. Rogers.

ORGANIC SALT & ACID CO.—Salicylic acid, sodium salicylate, salol, methyl salicylate, acetyl salicylic acid, and other salicylates. In charge of exhibit: Karl Kolbe.

OXYGEN PRODUCTS CO.

OZONE CO. OF AMERICA.—Apparatus showing the application of ozone to the purification of water and to the bleaching and deodorizing of liquids for industrial purposes; household ozone water purifier; ozone air ventilators; industrial and therapeutic uses of ozone. In charge of exhibit: William J. Eberle and C. O. Riedel.

PAJO CO.—Laboratory supplies and apparatus; filter paper, automatic water stills, Goerz polariscopes, Zeiss microscopes and refractometers, Meker furnaces and burners, Hess-Ives tint photometer, rhotanium. In charge of exhibit: L. A. Phluger and M. J. Seavy.

PARKS-CRAMER CO.—Completely assembled Merrill process system of fluid heat transmission, available for easy inspection; principal parts of the Cramer air-conditioning system. In charge of exhibit: Albert W. Thompson, Alexander B. McKechnie, Thayer Francis and Frank G. Bell, Jr.

PAYNE, STEPHEN T.

PENNSYLVANIA SALT MANUFACTURING CO.—Mineral acids, alums, alumina, lye, gas purifiers, caustic soda and soda products, sulphate of alumina for paper and color making, filtration, dyeing and tanning, chloride of lime, liquid chlorine, chloride of alumina, aluminate of soda and zirconia, Greenland krovolith. In charge of exhibit: Messrs. Hutchinson and James.

PERMUTIT CO.—Demonstrating outfits of Permutit water softeners and filters; photographs and drawings of commercial-size apparatus. In charge of exhibit: A. T. Smith, R. W. Eppe, M. F. Corin, J. S. Shedden and C. L. Boyd.

PERRY & WEBSTER, INC.—Consulting and designing engineers, formerly Kalbpery Corp., specializing in design of chemical plants; photographs of varnish plants, using new system of fume recovery. In charge of exhibit: Robert S. Perry, Paul W. Webster and Vern K. Boynton.

PERTH AMBOY CHEMICAL WORKS.

PETERSON, LEONARD, & Co.—Laboratory furniture for industrial laboratories and educational institutions.

PFAUDLER Co.—Acid-resisting fittings for use with the company's glass-enameled steel equipment; glass-enameled steel products. In charge of exhibit: P. S. Barnes, J. A. Cowles, R. L. Jacobs and T. D. Wilson.

PHILADELPHIA DRYING MACHINERY Co.—Three types of driers: Cabinet tray, tunnel truck tray and continuous apron. In charge of exhibit: B. P. Webster.

PHILADELPHIA QUARTZ Co.—Silicate of soda in its various forms, and its application in industry. In charge of exhibit: John D. Carter, C. F. Wolcott, W. H. Buxton, George W. Wait and R. C. Brown.

PITTSBURGH-DES MOINES STEEL Co.

PNEUMERCATOR Co., INC.—Various models of liquid measuring devices. In charge of exhibit: H. S. Parks and William Thomas.

PNEUMATIC SALES CORP., LTD

PORETE MFG. Co.

POWER SPECIALTY Co.—Uses of superheated steam in the chemical industry and the special developments of the Foster superheater for chemical manufacturers.

POWERS REGULATOR Co.—Automatic temperature regulators for hot water tanks, dyeing and bleaching machines; automatic water mixers, steam and water mixers, steam pressure reducing valves and other automatic temperature control apparatus. In charge of exhibit: H. W. Feige, F. A. Murray and O. F. Weilbacher.

POWHATAN MINING Co.—Exhibit of Powhatan asbestos filter fiber; demonstration showing uses of product in the laboratory. In charge of exhibit: Fred A. Mett.

PRATT ENGINEERING & MACHINE Co

PRECISION INSTRUMENT Co.—CO₂ and SO₂ recorders; single, 2 in 1 and 3 in 1 recorders; gas meters, gravimeters and calorimeters; single, 2 in 1, 3 in 1, 4 in 1 and 5 in 1 gages, flue gas analyzers and micrometer gages.

PROCTER & GAMBLE DISTRIBUTING Co.—Industrial soap, glycerine, stearic acid, red oil, pichene and stearine pitch. In charge of exhibit: T. E. Watters, H. G. Werner, J. D. O'Farrell, J. D. Cochrane, L. C. Minor and J. O. Pierce.

PROCTOR & SCHWARTZ, INC.—Proctor 12-tray laboratory drier; models of Proctor 3-conveyor drier for cotton, hair, wool, etc., and of Proctor 3-truck drier for chemicals, colors, etc.; samples of chemicals, colors, etc., dried in Proctor driers; projectoscope in operation showing Proctor drier installations. In charge of exhibit: E. B. Ayres, H. S. Landell, D. D. Hollenbaugh, E. A. Hults, C. W. Schwartz, Sd. S. Rhoads and Mrs. A. E. Reiter.

PROTECTO SAFETY APPLIANCE Co.

PROVOST ENGINEERING CORP.—Mixing machinery. In charge of exhibit: C. A. Bench.

PYROLECTRIC INSTRUMENT Co.—Pyrometric and electrical precision instruments, including Northrup pyrolyter, Compton electrometer, galvanometers, etc. A new type of resistance box and several other new instruments will be shown for the first time. In charge of exhibit: W. C. Harter and Harry L. Saums.

QUIGLEY FURNACE SPECIALTIES Co.—Furnace refractories; hysitemp, for bonding firebrick and granular refractories; carbo-sand for furnace linings and repairs; insulbrix for insulating furnace walls; heat-treating and powdered coal equipment. In charge of exhibit: W. S. Quigley, H. A. Kimber, J. H. McPadden, W. O. Renkin, F. W. Reisman, H. H. Harris, P. F. McGovern and C. Gantzman.

RARITAN ANILINE WORKS.—Aniline oil. In charge of exhibit: W. H. Van Winckel, H. D. Wellman and A. B. Hamby.

RAPIDAN COPPER WORKS—With Anaconda Copper Mining Co.

RAYMOND BROS IMPACT PULVERIZER Co.—Quarter-size models of the principal types of pulverizing machines in operation. In charge of exhibit: C. M. Lauritzen, F. I. Raymond, Joe Crites, S. B. Kanowitz and W. M. Cook.

RAYMOND LEAD WORKS.

REFINITE Co.

REPUBLIC FLOW METERS Co.—Steam, water, air and gas flow meters; low differential gas meter, Gebhardt portable indicating steam meter, CO₂ recorders, orifices and Pitot tubes. In charge of exhibit: T. A. Curran and George S. Hendrickson.

RESEARCH CORP.

REVOLVATOR Co.—Revolving and non-revolving, hand-power and motor-driven revolvers.

RHODIA CHEMICAL Co.

RICHARDS Co.

ROBERTSON HAMES LEAD WORKS.

ROBINSON, DWIGHT P., & Co., INC.

ROESSLER & HASSLACHER CHEMICAL Co., LTD.—Chloroform, cyanide, metal cyanides, trisalts, formaldehyde, hexamethylenetetramide, antimony salts, soda prussiate, metallic sodium and sodium peroxide, supplemented by a general line of chemicals. The special feature of this exhibit will be methyl chloride. In charge of exhibit: Herbert Gillis.

ROLLIN CHEMICAL CORP.—Barium, sodium and chlorine products. In charge of exhibit: J. G. Harrison.

ROTO Co.

RUGGLES-COLES ENGINEERING Co.—Model of drier and photographs of the installations. In charge of the exhibit: F. E. Finch, J. K. Towers and W. H. Glomb.

SARCO Co., INC.—Steam traps, radiator traps, temperature control apparatus, recording gas calorimeters and CO₂ recorders. In charge of exhibit: E. J. Ritcher, G. W. Bergen and others.

SCHAAR & Co.—Complete line of American-made laboratory apparatus and supplies; Schaar analytical balances. In charge of exhibit: A. E. Schaar and E. W. Ohman.

SCHAEFFER & BUDENBERG.—Recording thermometers and gages; a new type of thermometer not hitherto shown. In charge of exhibit: H. V. Carlier, F. Undeutsch and A. Campbell.

SCHWARTZ SECTIONAL SYSTEM.—Sectional filing cabinets for chemicals, reagents, samples and specimens; Schwartz auxiliary desk and chemistry desk. In charge of exhibit: M. P. Schwartz.

SCIENTIFIC EQUIPMENT Co.—Representative line of American-made laboratory furniture and apparatus, as manufactured and sold by the Kewanee Manufacturing Co. and the Central Scientific Co. In charge of exhibit: J. M. Roberts, S. L. Redman, A. B. Carter, Charles G. Campbell, O. T. Louis, R. S. Blodgett and Charles Ress.

SCOTT, ERNEST, & Co.—Photographs of machinery and apparatus installed by the company for the extraction of oils from nuts, seeds, tankage, fish waste; photographs of Scott evaporator for recovery of glycerine, caustic soda, paper pulp spent liquors, etc.; photographs of vacuum driers; plants for manufacture of ammonia, distilling fatty acids, manufacture of glycol and glycerine. In charge of exhibit: H. Austin, R. W. MacGregor and C. E. Bradley.

SCOTT, HENRY L., & Co.

SEMET-SOLVAY Co.

SEYDEL MFG Co.—Benzonates for medicinal use; furan-dyes. In charge of exhibit: Edmund E. Smith.

SEYMOUR & PECK Co.—Wooden shipping drums for dry chemicals. In charge of exhibit: C. B. Arnold.

SHARPLES SPECIALTY Co.—Models of laboratory and commercial super-centrifuges. In charge of exhibit: Max B. Miller, Aldus Wilbur and Homer Cloukey.

SHAWINIGAN ELECTROMETALS Co

SHAWINIGAN PRODUCTS Co.

SHAWINIGAN WATER & POWER Co.

SHERWIN-WILLIAMS Co

SIDCO Co. OF AMERICA, INC.—Complete line of fused silica ware made in America, for laboratory and industrial purposes. In charge of exhibit: Francis H. Ruhe, Walter J. Fensterer, and G. H. Mueller.

SIMMONS, JOHN, Co.

SLA, W. W., MFG. Co.—Operating unit of a dust-collecting, reclaiming and air-purifying system. In charge of exhibit: D. E. Hadley, E. J. Moore and M. M. Lowrie.

SOLVAY PROCESS Co

SOUTHERN COTTON OIL Co.

SOUTHERN OIL & CHEMICAL Co

SOUTHERN RAILWAY SYSTEM.

SOWERS MFG Co.—Operating exhibit consisting of Dopp seamless steam jacketed mixing kettles with different styles of agitators; Dopp seamless jacketed kettle arranged for oil heating; Dopp laboratory vacuum pan. In charge of exhibit: R. C. Boggess and others.

SPARKS, JOHN C.

STAMFORD DYEWOOD Co.

STAUFFER CHEMICAL Co.

STEIN, HALL & Co., INC.—Starches, gums and dextrines. In charge of exhibit: L. W. Peabody.

STERLING CHEMICAL Co.

STICHT, HERMAN A., Co.

STIMPSON EQUIPMENT Co.—Mitchell electric vibrating screen and miniature Janney flotation machine. In charge of exhibit: C. W. Stimpson, J. E. Klein and J. A. Lane.

STOKES, F. J., MACHINE Co.—Stokes rotary tablet machine in operation making naphthalene balls; powder filling machine in operation; rotary vacuum drier, laboratory

shelf vacuum drier, copper vacuum still, vertical surface condenser, automatic water still. In charge of exhibit: L. H. Bailey and C. F. Coleman.

STURTEVANT MILL Co.—Open-door ring roll mill, swing sledge mill and steel elevator; consultation on problems of crushing, grinding, pulverizing, screening, mixing, elevating, and conveying. In charge of exhibit: L. H. Sturtevant, W. T. Doyle and H. A. Tomlinson.

SULLIVAN MACHINERY Co.—Operating model of air-lift pump showing the application of the air-lift principle to the pumping of liquids. In charge of exhibit: John Oliphant, L. R. Chadwick and L. E. Gilbert.

SUNBEAM CHEMICAL Co.

SWENSON EVAPORATOR Co.—Two experimental size evaporators. In charge of exhibit: F. M. deBeers, P. B. Sadtler, G. Gordon Urquhart and F. F. Mackentepe.

TABER PUMP Co.

TAGLIABUE, C. J., MFG. Co.—Witham controllers for maintaining uniform temperature in paper machine driers; P & W condensate controller and liquid level controller. In charge of exhibit: Messrs. White, Dooling, Traudt, Dougherty and Wichum.

TAKAMINE COMMERCIAL CORPORATION.

TAKAMINE LABORATORY, INC.—Chemicals: arsaminol, neo-arsaminol, merpotide, merposol, boro tetramine, silver nucleinate, tuyol, hirathiol. In charge of exhibit: Jokichi Takamine, Jr.

TANNER, CHARLES S., Co.—Polyzime, for de-gumming and de-sizing in the textile industry. In charge of exhibit: C. Milton Tanner and William S. Newell.

TAYLOR INSTRUMENT Co.

TECHNICAL PRODUCTS CORP., INC.

TEXAS GULF SULPHUR Co.—In charge of exhibit: A. S. Cosler.

THATCHER PROCESS Co.—Anthraquinone. In charge of exhibit: W. H. Van Winckel, H. D. Wellman and B. Ives Cooper.

THERMAL SYNDICATE, LTD.—Vitresil, fused pure silica, for acid concentration, cooling and condensation; glazed vitresil laboratory apparatus; transparent vitresil tubing and utensils. In charge of exhibit: W. E. Strevig, S. L. Tyler and W. W. Winship.

THERMO ELECTRIC INSTRUMENT Co.—Freas and Thelco constant temperature ovens, incubators and other apparatus for laboratory use. In charge of exhibit: Royal B. Freas, Joseph LaMar and Edwin G. Price.

THOMAS, ARTHUR H., Co.—Laboratory apparatus and supplies. In charge of exhibit: R. M. Miller, H. C. Roak and C. C. Roberts.

THWING INSTRUMENT Co.—Temperature recording and indicating apparatus and some new paper testing instruments. In charge of exhibit: C. B. Thwing, E. J. Albert, H. K. Walton, J. H. Torrey and A. S. Hall.

TITANIUM ALLOY MFG. Co.—Ferro-carbon-titanium; opax, commercial zirconium oxide, for use in the manufacture of enameled ware and terra cotta; samples of material in which opax has been used. In charge of exhibit: William J. Evans and William V. Knowles.

TITANIUM PIGMENT Co.—Titanox pigments and various samples of paint, enamels, rubber, oil cloth, wall paper and printing ink in which these pigments have been used. In charge of exhibit: L. E. Barton and C. J. Kinzie.

T. M. & G. CHEMICAL Co.—Diethyl aniline. In charge of exhibit: W. H. Van Winckel, H. D. Wellman and William B. Whitmore.

TOLHURST MACHINE WORKS.—Operating demonstration of a new type of motor-driven suspended centrifugal machine suitable for heavy service in industrial chemical plants; open-top center slung centrifugal; standard self-balancing centrifugal with griddle bottom discharge; solid curb centrifugal with rubber-lined case and rubber covered basket; laboratory centrifugals. In charge of exhibit: W. C. Dutton, T. A. Bryson, John S. Gage, T. M. Stuart, B. M. Pilhashy and R. K. Cheney.

TYLER, W. C., Co.

UEHLING INSTRUMENT Co.—New CO₂ recording instrument for continuous measurement of percentage of CO₂; Uehling pneumatic pyrometer, draft gages and recorders, draft analyzers, pressure gages and recorders. In charge of exhibit: F. F. Uehling, C. J. Schmid, C. C. Phelps, and Wm. J. Reilly.

UNIFORM CHEMICAL PRODUCTS Co., INC.—Benzidine base. In charge of exhibit: W. H. Van Winckel, H. D. Wellman and C. S. Cooley.

UNION STEAM PUMP Co.—Complete pumping equipment for the chemical industry; vacuum and pressure pumps, steam, belt and motor driven. In charge of exhibit: R. W. Friedman, E. P. Ordway and K. D. Smith.

UNION SULPHUR Co.—In charge of exhibit: W. N. Wilkinson.

UNITED FILTERS CORP.—Working model of an American filter; Sweetland and United filter presses and samples of filter press plates and cloths.

UNITED LEAD Co.—Chemical lead-lined pipe fittings, valves, tanks; chemical lead-covered coils; hard lead centrifugal acid pumps. In charge of exhibit: C. B. Holden, G. H. Checkley, J. W. Spotten, C. R. Andrews, H. Freiherr and H. F. Hempel.

UNITED METALS SELLING Co.

UNITED STATES CAST IRON PIPE & FOUNDRY Co.—Barometric counter-current condenser in section with descriptive diagrams of operation; samples of casting for chemical and sugar industry; cast-iron flanged pipe. In charge of exhibit: H. A. Hoffer, J. D. Capron and C. D. Donaldson.

U. S. INDUSTRIAL ALCOHOL Co.—Photographs showing operation of plant; samples representing different stages in the manufacture of alcohol from crude molasses. Copies for distribution of chart showing uses of alcohol; new motor fuel "Alcogas." In charge of exhibit: B. R. Tunison.

UNITED STATES INDUSTRIAL CHEMICAL Co.—New chemical products, some of which have been manufactured in the United States during the past year for the first time. In charge of exhibit: B. R. Tunison.

U. S. SMELTING FURNACE Co.

UNIVERSAL ANILINE DYES & CHEMICAL Co.—Direct colors. In charge of exhibit: Stephen H. Eller.

UNIVERSAL OIL Co.

VALLEY IRON WORKS.—Autoclaves and sulphonators in laboratory and semi-commercial sizes. In charge of exhibit: Messrs. Senior, Mills and Jacobs.

VAN NOSTRAND, D., & Co.

VAN WINCKEL, W. H.—Aniline oil, aniline salt, thiocarbamilid, diethylaniline, H-acid, benzidine base. In charge of exhibit: W. H. Van Winckel and H. D. Wellman.

VITREOUS ENAMELING Co.

VULCAN DETINNING Co.

WAILLES DOVE-HERMISTON CORP.—Bituminous protective coatings and bituminous paints. In charge of exhibit: Willard T. Chevalier.

WALLACE & TIERNAN Co., INC.—Special chlorine control apparatus for use in bleaching paper and textiles, deodorizing, oxidizing and other chemical purposes; chlorine control apparatus for sterilizing water supply, sanitation of swimming pools and disinfection of sewage; valves, gages and flow meters for handling corrosive materials. In charge of exhibit: M. F. Tiernan, Wm. J. Orchard, L. H. Goebel, R. V. Donnelly and H. D. Thompson.

WARNER CHEMICAL Co.—Nelson electrolytic cell. In charge of exhibit: William B. Thom, John A. Chew and S. C. Mastick.

WERNER & PFLEIDERER—Kneading and mixing machines adapted to the chemical industry; laboratory-size mixers in operation; large-size steam jacketed machine; photographs of large installations. In charge of exhibit: A. J. Vollrath, J. C. Caley, S. D. Gridley and Miss E. Ziegler.

WESTINGHOUSE, CHURCH, KERR, INC.

WESTINGHOUSE ELECTRIC & MFG. Co.—A.c. and d.c. specially impregnated motors, arc furnace regulating and control panels, industrial heating appliances, starting switches, control switches, etc. In charge of exhibit: C. B. Gibson, C. G. Schluederberg and G. H. Jaspert.

WHEELER, C. H., MFG. Co.—Radojet air pump model, showing the inside; single and double stage radojet air pumps; duplex condensate pump; automatic steam pressure and temperature regulators. In charge of exhibit: G. L. Korthing and Charles Lang.

WHITALL TATUM Co.—Nonsol chemical glassware. In charge of exhibit: W. W. Figgis.

WHITLOCK COIL PIPE Co.—Special apparatus for heating water for use in chemical and industrial plants; coils of iron and steel pipe and copper tubing for use in chemical processes. In charge of exhibit: W. H. Ripley, E. B. Cole, S. T. Green, W. A. Evans and C. I. Babcock.

WIDNEY TEST LABS.

WILLSON GOGGLES, INC.

WOLF, JACQUES, & Co.—Sulphonated oils, softeners and finishing preparations; specialties for the textile trade; hydrosulphites. In charge of exhibit: Alfred Pfister, and Messrs. Deuble, Goss, Henckel, McDonagh, Griffith, Royce and Desmond.

WORTHINGTON PUMP & MACHINERY CORP.

ZAPON LEATHER CLOTH Co.

ZAREMBA Co.—Large-size photographs illustrating characteristic Zarembo evaporator installations. In charge of exhibit: H. E. Jacoby and W. H. Eggert.

Chemical Problems of the Beet Sugar Industry

Attainment of Greater Yields of Sucrose by Better Beet Culture and Improved Refining Processes Possible—Byproducts From Molasses: Potassium Carbonate and Sulphate, Methylamines, Cyanides, Methyl Alcohol, Ammonia and Bleaching Carbon

BY H. W. DAHLBERG*

THE chemical and chemical engineering problems in connection with the manufacture of beet sugar are many and varied in character. The extraction of sugar from the sugar beet involves the separation of sucrose from the organic and inorganic impurities with which it occurs in the beet. Since these impurities include all the soluble salts of the soil as well as a large number of vegetable acids and their salts formed during the growth of the beet, the process of sugar manufacture consists of the necessary steps to eliminate these non-sugars and obtain sucrose, $C_{12}H_{22}O_{11}$, in a pure form.

The average sugar beet has the following approximate composition:

	Per Cent		Per Cent
Sugar	16 00	Ash.....	0.60 to 1.00
Water.....	77 00	Organic non sugars.....	1.60 to 1.50
Mare.....	5 00		

The sugar content and purity of the beet varies considerably with the soil and with climatic conditions. By "purity" we mean the percentage of sugar contained in the total dry substance of the juice from the beet. The purity may vary from 80 to 88 per cent and the sugar content from 11 to 20 per cent or even higher. Beets of the highest sugar content and purity are, of course, the most desirable, as the yield of sugar obtained from such beets is high. A great deal of study has therefore been given to developing strains of beet seed which will produce beets of the desired quality. The fact that the present sugar beet containing 16 to 20 per cent sugar has been developed by breeding and selection from a small, wild beet containing practically no sugar indicates the progress that has been made.

The process by which sugar is obtained from sugar beets is briefly as follows: The beets are washed, weighed, and sliced, and the slices are treated with hot water in a series of tanks called a diffusion battery. During successive washings the sugar contained in the cells of the beet diffuses through the cell walls and is dissolved in the water, forming "diffusion juice," which is a dilute sugar solution of about 85 purity and containing about 12 per cent sugar. The diffusion juice is purified by successive treatments with lime, carbon dioxide and sulphur dioxide, filtered, evaporated to a sirup and then boiled until sugar crystallizes out. The final products obtained are pure granulated sugar and the byproduct molasses. The latter will be discussed more fully below.

The mineral salts present in the beet are very largely soda and potash, combined with organic and inorganic acids. As they are very soluble and are carried on through the process without much elimination, they are the most harmful of all the impurities. Each part of mineral non-sugar carries with it from $1\frac{1}{2}$ to 3 parts of sugar into the molasses, a byproduct from which no more sugar can be crystallized due to the concentration of impurities. For this reason it is highly desirable to grow the beets in soils and under such fertilizing conditions that a minimum of mineral salts is contained in the beet.

As an example, sugar beets grown in Germany contain approximately one-half as much ash as those grown in the United States, due to soil less rich in soluble salts and a more careful application and control of fertilizers. The result is that the yield of sugar is higher and the amount of molasses produced is much less than in our practice. It must be recog-

*Research Manager, Great Western Sugar Co.

nized, of course, that potash and other salts are absolutely essential for the growth of the sugar beet, so that it must always contain an appreciable quantity of mineral impurities.

MINERAL CONTENT OF BEETS, DIFFUSION JUICE AND MOLASSES

The following table shows the analysis of the ash from typical samples of beets and the diffusion juice and molasses produced from them. It should be borne in mind that in making the ash determination the salts of organic acids are broken up and the bases converted into carbonates. As the weight of the carbonates is considerably less than that of the organic salts from which they are derived, the ash content is always less than the actual content of salts.

Per cent lixiviated ash by weight	Beets 0.85	Diffusion Juice 0.53	Molasses 11.80
Analysis of ash:			
Silica and insoluble	2.64	2.00	8.6
Iron (Fe)	1.84	.22	11
Calcium (Ca)	.59	.44	51
Magnesium (Mg)	2.05	3.39	34
Potassium (K)	30.55	31.44	40.40
Sodium (Na)	11.28	11.05	8.68
Chlorine (Cl)	6.87	7.71	9.76
Sulphate (SO ₄)	3.61	5.92	10.74
Phosphate (PO ₄)	7.42	7.54	40
Carbonate (CO ₃)	30.98	30.43	28.74
Undetermined	2.17		
Total	100.00	100.14	100.54

With proper operation of the diffusion battery, from 20 to 30 per cent of the total ash in the beets is eliminated at this stage. As will be seen from the above analysis, the composition of the ash remains about the same in the juice as in the beets. Minor differences are caused by the mineral solids in the supply water. In securing high extraction it is, of course, just as important to have the purest obtainable supply water as it is to have beets low in mineral salts. It has been found that the loss of sugar in molasses is almost directly proportional to the amount of ash in the diffusion juice, indicating that the mineral non-sugars are much more melassigenic than are the organic non-sugars.

FACTORY INTERIOR: DIFFUSION BATTERY IN
FOREGROUND

The problem of a more complete separation of the sugar from the impurities in the beets is one which has received a great deal of study ever since the industry began, but still remains to a certain extent unsolved. If a cheap process of precipitating the sugar in an insoluble form, leaving the non-sugars in solution or vice versa, could be found, the yield of sugar in the form of granulated would be increased about 15 per cent, and the loss in molasses correspondingly reduced.

MOLASSES

The method of attack on this problem has been to allow the impurities and sugar to accumulate and be concentrated in the form of molasses, a material which contains 50 per cent sugar and 30 per cent non-sugars.

FILTER PRESS STATION

The sugar is then precipitated from the molasses as saccharates and finally obtained as granulated.

Molasses is a byproduct of beet sugar manufacture which offers very interesting possibilities for research work and the production of many further byproducts. As shown by the analysis given below, it is a mixture of a great many chemical compounds. The multiplicity of these has tremendously increased the difficulties of research work on this material, but considerable progress is being made. I might mention that under "Undetermined" may be included as many as twenty different organic non-sugars, gums, etc.

COMPOSITION OF BEET MOLASSES

Moisture	21.00	Invert sugar	0.06
Direct polarization	52.08	Ash	12.17
Sugar by inversion	50.51	Undetermined	15.41
Raffinose	0.85		

As mentioned above, although the molasses contains 50 per cent sugar, the non-sugars present absolutely prevent its crystallization, so no more sugar can be obtained by simple evaporation. Consequently it becomes necessary to use a precipitation process, such as the Steffens process, whereby the sugar is precipitated as tricalcium saccharate, and filtered from the mother liquor, called waste water. The Steffens process consists of dilution of the molasses, adding to the 5 per cent sugar solution finely powdered lime at a low temperature and with rapid agitation, until nearly all of the sugar is precipitated. The saccharate is filtered, washed and carbonated to liberate the sugar, finally giving a juice of about 90 purity, from which granulated sugar can be obtained.

One of the serious objections to this process is the relatively low purity of the saccharate produced, causing a reintroduction of impurities into the process. These impurities consist of a number of organic compounds which are precipitated by lime the same as sugar, and accumulate in the final molasses to such an extent that the yield of sugar from the Steffens process becomes too small to be profitable. When this occurs it becomes necessary to discard all of the molasses in process in the sugar factory and thus eliminate the objectionable impurities. The impurity which causes the most difficulty is the so-called "raffinose," as determined by the Clerget inversion method. This so-called "raffinose" is evidently in part true raffinose, and in part consists of other optically active compounds which have not been isolated and identified. Wherever the term "raffinose" is used in this paper it represents this unknown compound or mixture of compounds and not true raffinose.

RAFFINOSE

Several peculiarities have been noticed regarding the accumulation of "raffinose." One of these is that the calcium saccharate produced from molasses containing "raffinose" almost invariably shows an increase in raffinose, the total quantity present being 20 to 40 per cent greater than in the molasses itself. As yet no satisfactory explanation of this increase has been found. Another peculiarity is the fact that in climates where the beets are not exposed to freezing temperatures, as in California, no raffinose accumulates in the molasses, eliminating the necessity for discarding. Factories in localities with low temperatures during the manufacturing season, such as Colorado, Utah and Michigan, using the Steffens process, find it advisable to discard 25 to 40 per cent of the tonnage of molasses worked by this process. An analysis of discard molasses shows the accumulation therein of raffinose and organic compounds, the latter listed as "undetermined."

DISCARD MOLASSES

Moisture	20 13	Invert sugar	0 00
Direct polarization ..	56.90	Ash	11 87
Sugar by inversion ..	49 02	Undetermined	14 78
Raffinose	4 20		

There are two processes which may be used for the recovery of sugar from discard molasses—i.e., strontium or barium oxide form saccharates of higher purity than does lime. Several sugar companies are now experimenting with these two processes. The principal difficulty to overcome is the high cost of converting strontium or barium carbonates back to the oxide, as is necessary because of the original cost of these reagents. The conversion has been made in electric furnaces with some success, but at an excessive cost. The strontium process has been used extensively in Germany for many years, but has not yet been made a commercial process in this country. Both processes have the advantage over the Steffens process of producing a concentrated waste water which can be worked up for potash and other byproducts at less cost.

BYPRODUCTS FROM MOLASSES

The ash in molasses contains nearly 50 per cent of potash as K_2O and therefore is a valuable source for this material. Before the war this potash was not recovered by the sugar companies of the United States, it being impossible to compete with the price of potash

imported from Germany. During the last three or four years, however, large installations have been made to recover potash from beet molasses, and the recovery is being done very successfully. The Great Western Sugar Co. of Colorado now produces about 6,500 tons of ash of 40 per cent K_2O content annually. This is done by evaporating the waste water from the Steffens process in multiple-effect evaporators, burning the thick liquor in special furnaces, leaving the ash as residue. This material is now sold for fertilizer use, but may ultimately be refined and part of the potash secured as potassium carbonate, a more valuable product. In the process of refining, a considerable quantity of vegetable carbon is obtained, which may be utilized for the decolorizing of sugar solutions.

By the present process of burning the waste water liquor, nearly all of the nitrogen contained therein is lost. As the original molasses contains 1.5 to 2.0 per cent total nitrogen, most of which stays in the waste water, the recovery of the nitrogenous compounds offers great possibilities. Progress is now being made in the recovery of methylamines, cyanide and ammonia from this waste liquor. This will be done by destructive distillation, absorption and purification of the gaseous products.

A large portion of the nitrogen in molasses occurs in the form of betaine or trimethyl-glycocol, $C_5H_{11}NO_2$. This can be obtained in considerable quantities from beet molasses as beautiful crystals of betaine hydrochloride, a compound which is used to some extent medicinally for treatment of digestive disturbances.

On subjecting the betaine and other nitrogenous compounds to destructive distillation, a mixture of mono-, di- and tri-methylamines with ammonia is formed. Di-methylamine is a valuable raw material in the dye industry, and some of the addition products of the amines are attracting attention as accelerators in vulcanizing automobile tires. Constant research work is being carried on to determine the best methods to secure high yields and purities of the above-mentioned products from molasses. This is necessarily a slow process, involving, as it does, research in pure chemistry and the solution of the chemical engineering problems

SUGAR FACTORY UNDER CONSTRUCTION, SHOWING VACUUM PANS, CRYSTALLIZERS AND CENTRIFUGALS

encountered in developing the commercial process from the methods found successful in the laboratory. Some of the products are being made from molasses waste liquor in Germany, but very little information as to methods is available. It is also to be remembered that processes using excessive manual labor might be commercially successful abroad and fail in this country because of high labor costs. Consequently it is desirable to develop processes which are as nearly mechanical and automatic as possible.

FUTURE RESEARCH WORK

I will suggest several lines of research work to complete our present knowledge and develop a well-rounded process for the utilization of molasses. Such a process would yield the following known products, and it is possible that many others would ultimately be obtained:

Sugar	Methylamines
Potassium carbonate	Sodium cyanide
Potassium sulphate	Ammonium sulphate
Sodium carbonate	Methyl alcohol
Vegetable carbon	Vegetable tar

The individual steps in this process would be: 1. Recovery of sugar as strontium or barium saccharate. 2. Distillation of concentrated waste water. 3. Recovery and separation of methylamines, sodium cyanide, ammonium sulphate, methyl alcohol and tar as products of distillation. 4. Refining of crude still residue for the potash and sodium salts.

Still further products can doubtless be obtained by the distillation of the tar. The vegetable carbon may be used as a decolorizing medium or in the manufacture of shoe blacking.

Another line of work which has been suggested is the decomposition of waste water by electrolysis, which might yield caustic potash and valuable organic acids. With the advances which have been made in electrolytic cells and electrochemical processes during recent years, this line of attack offers attractive possibilities.

In the event that the extraction of sugar from molasses is not sufficiently profitable, a substitute process would be the production of yeast, alcohol or acetic acid. This is, of course, a commercial process now.

A highly desirable research work that should be taken up as soon as possible is the isolation and identification of the so-called "raffinose" and other optically active compounds. This will involve methods for the exact determination of each, and also methods for their removal from molasses without any destruction of sugar. I wish to emphasize that this problem is no mean task, and that some of the keenest minds in the sugar industry, both here and abroad, have already spent years in doing the pioneer work. Although the results of this work have been of great value, scarcely more than a beginning has been made.

A chemical engineering problem which deserves attention is the burning and grinding of lime under such conditions that it will give the maximum results in the Steffens process. A study of the values of various limes shows that the physical characteristics of any lime are almost as important as its chemical purity. For this reason two limes produced from the same lime rock and chemically active to the same extent may give rather widely different results in the precipitation of sugar. A very desirable quality in lime for the Steffens process is that it shall be light and fluffy in character.

The filtration and washing of the large quantities of

calcium carbonate and saccharate produced in beet sugar factories is worthy of more study. Although gratifying progress has been made during the last ten years, the industry is still in need of filtering apparatus which will give minimum sugar losses with low costs for labor, filtering media and evaporation of wash waters.

A byproduct of interest to the chemist is beet pulp, the residual beet slices after the sugar has been extracted. This material has considerable food value and is fed in either a wet, fermented state, or as a dry material. During fermentation of the wet material a very large loss of food value takes place, and the time may come when the chemist will develop uses for pulp which will utilize all of the values contained to a greater extent than is now being done.

In this discussion I have attempted to cover in a general way the lines along which scientific research and development is needed in the beet sugar industry, without going into any exhaustive treatment of the problems which we have to meet. It is perhaps not too much to say that in dealing with the byproducts of the sugar beet "only the surface has been scratched." Any success that the scientific men of the industry may attain in this direction will come with frank and open discussion and interchange of ideas and elimination of the secrecy which has hampered the development of so many chemical processes.

Denver, Col.

Chemical Control in the Sugar Industry

In the Aug. 7, 1920, issue of *The Louisiana Planter* S. J. Osborn, of the Great Western Sugar Co., writing on "The Chemical Control of the Sugar Industry," states that: While the sugar manufacturing process is not a highly complicated one, as chemical processes go, it is doubtful if any other manufacturing process is so closely and thoroughly controlled at every step by the chemical laboratory. The laboratory is called on for information and advice in solving the numerous technical problems which arise, and its assistance can be of the greatest value. One of the problems of the chemical department is the question of the extent to which work that does not have an immediate application shall be carried out.

In companies of sufficient size the chemical control work is handled by a specially organized chemical department entirely independent of the operating department, although the two naturally enjoy intimate relations and must work in close co-operation to achieve the best results. This system has many advantages. Not only does it relieve the operating department of responsibility for a highly technical line of work, but it puts the results on a basis where they are free from even any suspicion of bias or irregularity, and facilitates the introduction and use of uniform methods in analysis and control.

An important factor in the development and application of chemical control in all branches of the sugar industry is the extent to which rapid and reliable control methods have been worked out.

The chemical department of a sugar plant usually has a wider field than that its name might imply. It issues and is responsible for almost all of the important operating reports, other than the financial, and keeps a detailed set of records with the help of which the operating efficiency of the plant might be improved.

The Problems of the Petroleum Industry

Greater Supplies of Crude Oil Required to Meet Future Demands—Better Utilization of Supplies Necessary—Pyrolysis of Fuel Oils Into Gasoline—Substitutes for Petroleum Products—Chemical Synthetic Products From Petroleum

By WILLIAM A. HAMOR*

BENJAMIN SILLIMAN, JR., who conducted the first technicochemical investigation of crude petroleum, in 1855, remarked that it was a raw material from which might be manufactured very valuable products. With an industrial history covering a period of but sixty years, crude petroleum now is recognized as a resource of the highest economic value to society because it is essential to agriculture, manufacturing, commerce and the pleasures of life. It is the source of gasoline, which is responsible for the development of the internal-combustion engine, the increase of the use of which has strengthened the entire aspect of modern civilization; it gives the world its supply of illuminating oils, which, by bringing a cheap light to millions of people, have constituted America's greatest gift to the uncultured peoples of the globe; and it provides the lubricating oils upon which the complex mechanical equipment of today is dependent for its operation. Then, too, part of the industrial activity of our country rests upon another petroleum product, fuel oil, which also is required for the operations of an oil-burning navy.¹ The fact that crude petroleum forms the basis for a chemical products industry of almost unlimited possibilities of development, and as distinctive as the coal-tar industry of the present, brings out, in addition, its predominant importance among mineral raw materials.

A substitute has been found for crude petroleum, but shale oil, to which reference is had, is a chemical product and therefore is subject to economic limitations not applicable to a substance which may be mined and handled so easily as crude petroleum. Indeed, the availability and magnitude of the petroleum resource have given confidence for the extensive mechanical developments essential to its use; and accordingly the employment of petroleum is established among the practices and requirements of modern life. As pointed out by Gilbert and Pogue,²

Any tendency toward disuse of its essential products, either through undue increase in price or from decline in production, will mark a turning point in material comfort and industrial advantage, the deferring of which becomes an object of universal concern. As the petroleum deposits of the United States have been drawn upon with extraordinary rapidity and the supplies have already suffered serious depletion, the matter of their approaching exhaustion assumes the light of immediate importance. The comforting assertion that such considerations may be safely left to future generations does not apply to petroleum.

Crude petroleum now is being taken from the ground in the United States at a rate approaching 400,000,000 bbl. per annum. This is five times the rate in 1901 and

twice that of 1909.³ At the close of 1919 approximately 4,986,300,000 bbl. of crude oil had been produced in this country since the first well was drilled at Titusville, Pa., in 1859. This is about 43 per cent of the original recoverable content, as estimated by the United States Geological Survey. All this oil that has been mined in the United States in sixty years would be taken out in thirteen years at the present rate of production. Impressive as this fact may be, it is not so disturbing as the realization that the recoverable crude petroleum in this country, according to the conservative estimate, would probably be practically exhausted in seventeen years if the 1919 rate (nearly 380,000,000 bbl.) of production could be maintained for so long, while a reserve of 7,000,000,000 bbl., the moderately liberal estimate, would disappear in eighteen and one-half years.⁴ If an improbable excess of 2,500,000,000 bbl. over the estimated amount is present, this excess would be sufficient to sustain the present draft for six and one-half years additional.

What improvements will in the next ten years be made in the process of extraction of crude oil from the ground, and what the effects may be in recovering the great amounts of crude petroleum not "available" or recoverable by present methods, remains to be seen. It is probable that not much over 20 per cent of the oil underground is brought to the surface. It is most important that studious attention be given to the problem of the more complete extraction of the petroleum than is possible by the methods now in general use. Records of wells should be kept, surface and underground geology should be correlated, oil-sand should be examined, and if possible underground losses should be determined. The estimated available supply should be increased in this way to the maximum. It is noteworthy that while the petroleum industry has been supplied with technical means whereby certain wastes in production may be combated there has been provided no adequate machinery for applying this knowledge.

Fortunately, however, the crude petroleum cannot so soon be taken from the ground. Even unparalleled prices for crude oil, and exploratory work far more extensive than that now in progress, cannot within the next generation disclose all the oil pools in the strata; and although devices for more rapid extraction may be invented and applied, the fields which remain to be discovered cannot be drained so rapidly. Oil pools will be found, finally by accident, long after the search has waned, and even in the next century. These are some of the reasons why the production of natural petroleum in the United States must pass its peak at an early date—probably within five years and possibly within

*Assistant Director of the Mellon Institute of Industrial Research of the University of Pittsburgh.

¹Forty-eight per cent of the power used by the British Navy in the European war was derived from petroleum and the fleet steamed 7,000,000 miles per month. In 1918, 3,000,000 tons of fuel oil were shipped from the United States to the Allied navies.

²U. S. National Museum, Bulletin 102, I, ii, p. 29.

³See "World's Production of Petroleum," U. S. Geological Survey, Jan. 22, 1920.

⁴Dr. David White, of the United States Geological Survey, has furnished these data.

three years—while the long sagging production curve may be carried out beyond the century. It is certain that this country must in the near future lose its supremacy in the petroleum world and become more and more dependent on the oil resources of other lands,⁵ except in so far as the situation may be saved by the successful production of artificial petroleum (crude shale oil) by the destructive distillation of American oil-shales.

To depend on oil-shale, however, is to trust to uncertainties both as to costs and as to ultimate results, and is at best to superimpose on our present social and industrial fabric an enormous and complex new industry rivaling in part our coal-mining, salvaging but a part of our present petroleum industry, and requiring many years for its development. Sooner or later—perhaps within five years—a commercial shale-oil industry may be born in this country, but that it can originate soon enough or become large enough to offer any considerable contribution before our domestic petroleum production is already on the wane seems improbable. Finally, if shale oil yielding the principal and indispensable petroleum products cannot successfully be produced and marketed as cheaply as natural petroleum

method of treatment of any particular oil-shale. This valuable pioneering work would bear fruit ultimately in the production of a notable volume of shale oil.

A British oil economist has calculated that by 1925 the petroleum requirements of the United States will exceed 500,000,000 bbl. and that at a later date our country will become more and more dependent upon British supplies. An American authority, W. C. Teagle, president of the Standard Oil Co. of New Jersey, has estimated that in 1925 the requirements of the petroleum industry in this country will approximate 650,000,000 bbl., an increase of more than 220,000,000 bbl. over the requirements of 1919. Unless conservation of petroleum through curtailment of use—for example, as fuel burned under steam boilers to generate steam—is forced automatically by the scarcity of crude oil and consequent prohibitive prices, or is sooner and more wisely brought about artificially by regulation, it seems probable that the demands of the American petroleum industry will considerably exceed 600,000,000 bbl. or possibly 650,000,000, as estimated by Teagle, in 1925, although by that time our exportation of refined oils to some of the foreign markets will probably be reduced by the competition of foreign oils nearer at hand and more cheaply produced.

A drain of over 500,000 bbl., even if the yearly effective demand be not further increased, would, if taken from the oil fields of the United States, probably exhaust the petroleum resources remaining available in the ground in fourteen years, or in sixteen years if it is assumed that the recoverable petroleum possibly amounts to so much as 8,000,000,000 bbl., which seems very improbable to geologists. It is fortunate for the country that the petroleum cannot be extracted so rapidly. On the other hand, it also seems quite improbable that an annual production of natural petroleum amounting to so much as 450,000,000 bbl. can be won in any year from our domestic oil fields, the peak of whose production is likely to be passed by 1925.

All circumstances being considered, it must be expected therefore that, unless our consumption is checked, by 1925 the United States will be dependent on foreign oil fields to the extent of 150,000,000 bbl., and possibly as much as 200,000,000, of crude oil each year, except in so far as the situation may by that time, perhaps, be helped to a slight extent by shale-oil. Add to this probability the other greater probability that within five years—perhaps three years only—our domestic production will begin to fall off, with increasing rapidity, due to the exhaustion of our reserves, and it becomes evident that, except for such relief as may come from shale-oil production, the future of the United States in petroleum will yearly become more and more completely dependent on supplies to be brought from foreign fields.⁶

As the outlook now must be viewed, it is practically certain that after a time the United States will be buying petroleum from commercial rivals in quantities greater by far than ever have been sold to them, to make no mention of the prices paid. But, while this may be impreventable, it should be escaped as far as

FIG. 1. OIL SHALE ON WILLOW CREEK, SOUTHWESTERN UTAH COUNTY, UTAH

from other countries, the public cannot be expected to build up and sustain a shale-oil industry, unless it be under subsidy as a protective measure.

To date approximately 140 shale-oil companies, many of which claim to own or control novel distillation processes, have been formed in the Western oil-shale fields; but so far none of these organizations has assumed a position of commercial importance. However, research of a fundamental character is being carried out by various large petroleum interests and by the Bureau of Mines. It is hoped that the Bureau of Mines will serve the useful function of investigating new types of retorts and of determining the most profitable use and

⁵On the restrictions imposed by certain foreign countries upon citizens of the United States in prospecting for or acquiring lands containing petroleum, see Senate Document 272, May 17, 1920.

⁶United States interests are practically supreme in the commercial control of the petroleum resources of the Western Hemisphere, dominating the petroleum industry in the United States, Canada, Mexico and Peru, and holding substantial interests in Trinidad and Venezuela and in the prospective petroliferous areas in Central America and Colombia. Their only competitors are British and British-Dutch interests, which control the petroleum situation in Trinidad and are not only strongly entrenched in Mexico and Venezuela but are aggressively seeking to enlarge their holdings in those countries and to gain footholds elsewhere.

possible. If our nation is to have these oils as cheaply as they are sold in the home countries; if our industries, our transportation, our navy and our standards of living are to be safeguarded in advantages as great as those of our rivals, and if our merchant ships are to obtain their fuel oil at prices as low as those paid by rival ships, the oil supplies needed must be in our control. Our prosperity and our prospects, so far as they may be affected by this important commodity which influences the daily life of every citizen, must not be subject to prejudicial regulation or discriminative restriction by any foreign power. Only by assuring American control over the petroleum supplies required by the United States can the protection of our future be guaranteed.

Experts believe that the most conspicuous developments affecting the sources of the world's supply of petroleum in the next decade will occur in the countries that border the Caribbean Sea and the Gulf of Mexico. Within the last four years the annual production of petroleum in Mexico has increased from 21,000,000 bbl. to 56,000,000 bbl.¹ and the potentialities of future production in that country have been demonstrated. It is estimated by T. C. Thomson² that the ultimate expected production will equal, if not surpass, the whole production of the United States. Its product, originally considered valuable only as a source of fuel oil, now is yielding, by modern refining methods, increasingly important percentages of illuminating oils and gasoline. The hindrances to enormously increased production are unsettled political conditions and inadequate facilities for marine transportation, but these obstacles doubtless will be surmounted within the next few years.

To summarize, the future domestic supply of crude petroleum will not be equal to the future home demands. This problem can be met by:

- (1) Obtaining greater supplies of crude oil—
 - (a) By increasing the importations from foreign oil fields.
 - (b) By actively participating in the development of foreign oil fields.
 - (c) By the establishment of a shale-oil industry on a commercial basis as soon as is practicable.
 - (d) Through increased recovery from our oil fields, resulting from more efficient operating methods, and especially the elimination of wastes in production.
- (2) A better utilization of the crude now available, principally—
 - (a) By the pyrolysis of fuel oils into gasoline.
 - (b) By the development of gasoline substitutes.
 - (c) Through the development and use of Diesel-type engines utilizing the heavier fuel oils.

PROBLEMS IN THE PRODUCTION OF CRUDE PETROLEUM

Among the development and production problems which require more study are the dehydration of emulsified petroleum and the prevention of its formation in oil wells. It has been learned that probably all emulsions in wells are formed after the oil has left the sand, and their formation often can be prevented. The systematic investigation of methods for excluding water from oil and gas wells, of the effect of water on the

production of oil wells, and of casing and tubing problems, would lead to findings of technical value. Work on the employment of safety devices in the oil fields, the possible substitution of explosives safer than nitroglycerine for shooting oil wells, and the effects of shooting on wells, would be of utility. Scientific inquiries for determining the capacities and characteristics of oil and gas sands, the proportions of petroleum not being recovered by present methods of production, and the laws governing the expulsion of petroleum from the oil sands have been started by our energetic Bureau of Mines. There is little information on this subject, and it will not be possible to interpret data and to judge the value of various methods of production until the underlying geochemical laws are better understood. Procedures for stimulating production and increasing the recoveries of petroleum from the sands, including the effects of vacuum pumping, use of compressed air or gas, and use of water flooding, present other opportunities for research. In this connection, pumping problems and equipment, including the use of automatic air and gas pumps, electrical equipment, and air lifts should be given attention.

Storage and transportation problems include losses of oil in storage, prevention of fires at tanks and wells,³ the flow of oils in pipe lines, and the construction of storage tanks and reservoirs.

SOME PROBLEMS IN REFINERY TECHNOLOGY

Petroleum industrialists frequently have availed themselves of the service of scientific research⁴ both in the development of processes and in the perfecting of the necessary mechanical equipment. In fact, marked success has attended scientific progress in the refining of petroleum, and the largest refineries now concede that chemistry is the source of specific information for the petroleum industry and gratefully acknowledge that the efficiency of their plants has resulted largely from properly conducted scientific investigation. Those companies which stand well to the fore maintain one or more research laboratories, and industrial research has left its mark on their development. It is, however, essential, particularly for the future welfare of the industry, that there be an increment in investigational activity. This may be brought about in a measure by the organizations represented in the petroleum industry, especially the American Petroleum Institute, and by the Bureau of Mines; but there must be more co-operation between petroleum industrialists and the universities and scientific societies if the desirable fruitful research is to be stimulated.

The need of continuous study and research and training in hydrocarbon chemistry and in petroleum technology cannot be over-emphasized.⁵ The lack of reliable general information has worked handicaps on the petroleum industry, which is, in many ways, groping in the dark. Similar errors are made repeatedly in the same territory by different operators, and both in

¹On oil fire hazards, see Bulletin 170, Bureau of Mines.

²A good illustration of what research has done in working out refining problems is had in the case of liquid petroleum. At the beginning of the war a great shortage of this product occurred, since its manufacture had been carried on solely by the Germans from Russian petroleum stock, which was thought to be the only suitable basis. After scientific inquiry the manufacture of liquid petroleum was begun on American oils, and the present American product is superior to the old German "paraffinum liquidum" in a number of respects.

³It is gratifying to note, however, that at least one American institution now is supplying trained petroleum chemists to the industry. Reference is had to the University of Oklahoma, where Prof. F. W. Padgett is giving systematic instruction in hydrocarbon chemistry and refinery technology.

⁴In the same period our imports of Mexican crude petroleum have increased from 15,175,061 bbl. to 45,893,945 bbl.
⁵*J. Inst. Pet. Tech.*, vol. 5, p. 56.

drilling and in refining the various factors having a known influence are understood imperfectly in their relation one to another. Geology, the real foundation of a study of production, is insufficiently applied or understood by the average producer, and in consequence much of the production is accidental rather than scientific. When a producer finds petroleum he is simply a producer, and not a marketer, for he has usually no knowledge of the value of his product other than the posted price. He knows only in a rather vague

FIG. 2. A BATTERY OF 1,200-BBL. CRUDE OIL STILL'S OF THE LATEST DESIGN

way what characteristics are valuable; and when he has sold his crude oil he frequently is concerned no longer with the petroleum industry. The refiner usually has only the knowledge gained by an apprenticeship with an older refiner, and is therefore nescient regarding the chemistry of refining.

Petroleum marketers consider that the greatest need of those engaged in the petroleum industry today is uniformity in methods of testing and in the physical instruments employed therein. Constant progress is being made in the analytical chemistry of petroleum and its products, but much research will be necessary before precise and detailed procedures are worked out which will be satisfactory for general adoption. It is not practicable to issue standard test samples, as is the case for the iron and steel industry, but there can be laid down definite, standard instructions for carrying out the various operations involved.

A large literature already exists on the subject of analytical naphthology owing to the activities, among others, of the Bureau of Mines and the Bureau of Standards in the United States and of the National Physical Laboratory in England. What is needed now is the welding of these researches into a comprehensive whole by an international body of experts, which, sitting permanently like the pre-war International Petroleum Commission, shall institute researches into new methods of procedure and revise existing technic.

From the industrialist's viewpoint, the great problem in the petroleum industry is flexibility in refining, in order that there may be produced only those products which are in demand. In other words, there is wanted a suitable process which will enable the refiner to manufacture only the products for which there is a big market—say gasoline and lubricating oils. Re-

search has been begun which has for its object the production of the desired finished oils, and only these, by purely physical methods, thus dispensing with chemical treatment.

Considerable investigation has been devoted to working out processes for the dehydration and desulphurization of crude oils and for the pyrolysis of heavy oils (particularly the conversion of such oils into motor fuel). Findings of importance have resulted from these investigations, but the ideal processes remain to be found, especially methods for converting products of the destructive distillation of residuum or heavy oils into saturated hydrocarbons. If hydrogenation could be conducted successfully on a commercial scale the customary treatment with sulphuric acid could be dispensed with. Hydrogenation with platinum black or nickel could be accomplished if an antidote were known for the poisonous effect of sulphur compounds on the catalyst. Another matter of interest here is the polymerization of olefines; this subject requires the consideration of research.

Automotive engineers should have available exhaustive data regarding the specification and use of petroleum products for internal combustion and lubrication purposes. Lubricating oils for special purposes have not received due scientific attention, and, as a result, the selection of a lubricant is more frequently casual than scientific. Lubrication is a special problem of colloid physics.¹²

It is singular that the subject of refining has attracted so little notice. In the chemical treatment of petroleum products systematic investigation, with the object of ascertaining the most favorable temperatures for the acid treatments of petroleum distillates, would be of practical value as affording an indication to the refiner how to proceed under all circumstances. Another well-known problem in refining is the chemical treat-

FIG. 3. A BATTERY OF AGITATORS, EACH OF ABOUT 1,200-BBL. CAPACITY

ment of lubricating oils in such manner as to minimize the losses and to prevent the emulsions which result when sulphuric acid is used. The production of persistent emulsions in the refining of petroleum is a problem to be attacked from the colloid-chemical point of view. An economic process is needed for isolating pure naphthenic acids of high molecular weight from

¹²In fact, W. B. Hardy (*J. Soc. Chem. Ind.*, vol. 38, 1919, p. 7T) has shown that we may look with confidence to colloid chemistry to assist us in finding the lubricants of the future.

waste lyes. A related problem is the utilization of the esters from the naphthene carbo-acids contained in the residue from the alkali treatment. A question of interest here is: What is the cause of the cacodor of naphthenic acids, and how may these products be deodorized most effectively and economically?

The following are some of the many other problems confronting petroleum technologists: A more rational utilization of the butanes and pentanes in natural gas gasoline and in light petroleum fractions; does the hot still metal exert any catalytic action in the pyrolytic decomposition of residues; the minimization of the decomposition of sulphur compounds during the distilla-

FIG. 4. TWO AGITATORS OF THE LATEST TYPE, 20 FT. IN DIAMETER AND 41 FT. 10 IN. HIGH

tion of petroleum containing asphalt; what role do sulphur compounds take in the condensation of petroleum to asphalt; increasing the efficiency of tower stills, condensers, and heat exchangers; the rapid and effective revivification of spent fullers earth; the separation of the aromatic and cyclic unsaturated hydrocarbons from the paraffine and naphthene hydrocarbons by a more satisfactory reagent than those now in use; the fractionation of petroleum residues containing paraffine wax into a distillate and undecomposed amorphous wax; the elimination of gummy or asphaltic portions from wax distillate by a distillation or mechanical procedure; what constituents of a mineral oil are responsible for the lubricity thereof, and can the lubricating properties of an oil be increased in the light of this knowledge; the prevention of the oxidation of mineral oils in transformers; products which will make emulsions with water without any oil coming to the surface; and a rational plant for producing oil gas from tar and carbon monoxide from the residue, the mixed gases to be suitable for use in gas engines. Then, too, notwithstanding the many processes which have been patented, the "solidification" of petroleum and its products is still under investigation.

The collection of data on the physicochemical properties of petroleum and its products for the use of refinery chemists and engineers is one of the most important inquiries which could be instituted, and it is hoped that the Bureau of Mines will cover this field in its broadest practical aspects. The data obtained on the pure hydrocarbons which exist in crude petroleum also would be of value for purposes of comparison.

"Cracking," or pyrolysis, is regarded as the leading potentiality in petroleum refining, no less so because it

permits the production of the main products according to demand, without sacrifice of byproduct possibilities. The importance of the whole matter may be evaluated by having regard to the fact that at present, even with "cracking" well launched into practice, less than one-half of the petroleum produced is manufactured into products representing an ideal apportionment of the raw material into its components. The manufacture of gasoline may be doubled eventually or even more greatly multiplied without increasing the production of crude petroleum.

The research activity on the subject of "cracking" has been notable, and the volume of patent applications shows no signs of diminution; in fact, the number of permutations and combinations of the variables borders on the infinite, and accordingly, while modifications of outstanding novelty will be rare, a variety of processes remain to reach the Patent Office. At the present time investigators are endeavoring to obviate the defects in nearly all the methods now in use, which are: (1) the accumulation of carbon, (2) loss of oil as fixed or permanent gas, (3) low yields, and (4) the formation of undesirable impurities.

The inclination to look upon the unsaturated products of "cracking" as valuable for synthetic chemistry is becoming pronounced. The fact that under high pressure the point of molecular scission is directed to the middle of the hydrocarbon chain, while at low pressure the point of rupture is displaced more toward the ends of the chain, holds out additional promise for the working out of commercial processes for the manufacture of isoprene, etc., from petroleum.

An insufficient amount of work is being done in a systematic way to show how to economize in the use of gasoline. A thorough investigation of carbureters and

FIG. 5. CURVE SHOWING THE GROWTH IN DEMAND FOR GASOLINE COMPARED WITH THE GROWTH IN OUTPUT OF CRUDE PETROLEUM

fuels, and certified tests of the performance of all makes of automobiles, would be of value in economizing in the use of gasoline, and giving the public as much service as possible for a given expenditure. The Bureau of

Mines and the Bureau of Standards have studied different phases of this question, but neither has been able to conduct as much research as should be done. With over 7,000,000 of gasoline-driven automobiles in daily use, and motor gasoline constantly rising in price, the American public cannot afford to have the Government fall short in a matter of so great economic importance and of serious personal concern to so many.

A very pertinent question is, Should a higher final boiling point for gasoline be permitted? A final boiling point of 230 deg. C. would increase the available supplies by a considerable percentage, while greater efficiency in fractionation would result probably in an additional 10 per cent increase in yield.

PETROLEUM SUBSTITUTES

Even with the most efficient use of the remaining supply of petroleum and an appropriate development of shale oil in prospect, the petroleum situation can be improved additionally by a progressive utilization of substitutes for gasoline and fuel oil, so as to give better economic balance by relieving the products upon which fall the heaviest demands. Two substances, benzol and ethyl alcohol, are suitable for assisting gasoline, and offer the advantage of a record of successful use in motor engines in Europe prior to the war, and of a marked extension of utilization there under the rigorous conditions of the present, while coal and hydro-electricity may be brought to the aid of fuel oil.

SUBSTITUTES FOR GASOLINE¹

The subject of gasoline substitutes is one of particular interest, although definite information concerning it is decidedly limited because of the paucity of research which has been made public. The first point of importance to mention here is that motor fuel is essentially a source of energy and that the energy must come from somewhere. Interesting stories regarding the discovery of new fuels appear from time to time in the newspapers, these fuels often being prepared by adding a small quantity of some secret compound to water. That these "fuels" are one and all without particular value is established by the fact that water contains about as little available energy as any substance which could be selected.

With respect to the real possibilities of gasoline substitutes, it now seems probable that later on shale oil may become an important source of motor fuel. Oil-shale probably will not assume any considerable industrial importance in the immediate future, but its potentiality as a resource gives a comfortable feeling of assurance that the use of motor vehicles will not have to be discontinued when crude petroleum becomes too valuable for fuel purposes. Substitutes for gasoline should receive every encouragement if produced and marketed in an intelligent and scientific manner; for our country needs to increase its motor fuel resources and no step in this direction should be hindered. It should be recognized, however, that petroleum gasoline is a type of fuel for which present equipment has been designed and for which it is eminently satisfactory. It is believed, therefore, that when striking claims are made for the superiority of any gasoline substitute these should not be taken too seriously. The substitute fuel should be given a fair trial, but the user should be satisfied if it is as good as gasoline and should not expect it to be remarkably superior.

The type of gasoline substitute which is of most importance at the present time is the mixture of hydrocarbons, including benzol, toluol and xylol, obtained as a byproduct in the coking of coal. During the war the benzols were used largely in the production of explosives and other munitions, but since the termination of hostilities a considerable supply has been rendered available for motor fuel. In fact, several companies are marketing benzol mixtures, generally mixtures of the benzols with petroleum naphtha. These products have been used under widely varying conditions, and in most cases favorable results have been obtained.

The use of light oils from coal as motor fuel does not, however, offer an ultimate solution of the motor fuel problem, since the total production of these hydrocarbons is rather limited. The quantity of light oil produced from coal in byproduct coke ovens during 1919 has been estimated at 90,000,000 gal., or about 2.3 per cent of the total amount of gasoline produced in 1918.² The actual figure for hydrocarbons suitable for motor fuel is even less than that for total light oil produced, and it appears, therefore, that, as a motor fuel resource, the benzols are of relatively small importance. To illustrate, it may be stated that since 1916 the production of gasoline has practically doubled, while the quantity of coal mined has increased only about 17 per cent. The real importance of the benzols as motor fuel occurs in districts adjacent to byproducts coking operations, where a reasonable proportion of the local gasoline supply may be filled by coal byproducts.

In a certified dynamometer test by the Automobile Club of America 90 per cent benzol showed 12.3 per cent less fuel consumption than gasoline. At the same time the horsepower was increased, depending on the speed. At 2,000 r.p.m. this was 19.4 per cent greater than that of gasoline. The higher ignition point of benzol also eliminates "knocking" (pre-ignition). It is known that the benzols, if properly used, are very satisfactory motor fuels and that there is no difficulty in finding a market for the entire supply.

ETHYL ALCOHOL AS A MOTOR FUEL

Denatured ethyl alcohol has possibilities for the future and is being developed to a certain extent. It is interesting to note in this connection (1) that fuels with ethyl alcohol base have recently been used with success in motor vehicles in this country, in Europe, and especially in South Africa; and (2) that new sources for the production of ethyl alcohol are being discovered constantly. In addition to the generally known vegetable sources, methods have been developed for the production of ethyl alcohol from sawdust³, from refuse of cane-sugar manufacture, from waste sulphite liquors, from calcium carbide, and recently, in England, at the Skinningrove Iron Co.'s works, from coke-oven gas.⁴ As the largest and best-known field of the consumption of ethyl alcohol in this country has been destroyed for the time being, its use for power purposes would not meet with the competition which it formerly would have had and the price of ethyl alcohol should not be high, especially as compared with the prices of gasoline now prevailing and expected in the near future.

²Even if all our coke were manufactured in byproduct ovens the amount of benzols recoverable would be only about 10 per cent of the annual consumption of gasoline.

³It is possible to get 10 to 12 l. of alcohol from 100 kg. of sawdust. There appear to be possibilities in the development of the production of alcohol from wood.

⁴Bury, *Iron and Coal Trades Rev.*, Dec. 19 and 26, 1919.

There are certain difficulties in the way of the wide use of ethyl alcohol as a fuel, which are of a non-technical nature and hence will not be discussed here. It may be stated, however, that the discovery of a cheap, positive and reliable denaturant would go a long way toward making possible the wide adoption of alcohol for power purposes; and that the development of cheaper methods of production and of suitable types of engines are also problems of pertinence.¹⁸

Alcohol-benzol-naphtha mixtures are in use and have been found to be satisfactory in the present types of automobile engines. "Alcogas" is another product which has aroused interest among automotive engineers.

It would be desirable to institute broad researches (1) on the combustion of alcohol and alcohol mixtures, and (2) on lessening the cost of denaturing. In connection with (1) the operation of a fleet of cars and trucks fed with such mixtures would provide data of importance.

FUEL OIL SUBSTITUTES

Fuel oil has come into extensive use in the United States, especially in the far West, as a substitute for coal.¹⁹ It is more convenient than coal and therefore is adopted by industries wherever its price is low enough to permit its use. Its employment in this way cannot be sustained, in view of the slowing rate of petroleum production and the counter-demand that will come in increasing measure from the further development of pyrolytic practice in refining and from the wider adoption of the Diesel type of internal-combustion engine. It soon will be necessary, therefore, in any event, to bring coal and hydro-electric power to the aid of a growing number of those activities now dependent upon oil fuel; and the whole matter may be facilitated by constructive action in respect to coal and water power, to make their service more immediately available.

The use of the tar obtained in byproduct coking (9 to 10 gal. per ton) for fuel, especially in steel manufacture, has increased rapidly during the past few years, and many of the larger steel companies, operating their own byproduct coke plants, do not sell any of their tar for distillation purposes, but use it exclusively for fuel. In open-hearth practice the consumption of tar per ton of steel is reported to be 10 per cent less than the consumption of fuel oil. It is used advantageously in combination with producer gas. The resulting flame has a much better melting efficiency than that of straight producer gas, and the increase in the capacity of the furnace is much greater than would be accounted for on the basis of the heating value of the fuel used. These considerations are of great moment, in view of the increasing price of fuel oil and at a time when the maximum output per unit of investment is essential. The price of approximately 4c. per gal., that has until recently been paid by tar-distilling companies for crude tar, is much too low to meet competition with the real fuel value, and the future is bound to see a scarcity of tar for distillation, which will result in a considerable increase in price.

INCREASING THE USEFULNESS OF FUEL OILS

It is of interest to note what has been done recently to supplement mineral oils or to increase their useful-

ness through research. The work has been carried on in several directions, of which the following may be mentioned, without, however, indicating the relative importance of the various remedies.

Processes have been devised for making stable mixtures of tars with mineral oil by using pitch-containing tars, asphaltic residuum and a suitable distillate. It also has been found that fuel oils or residues may be reduced in viscosity by piezochemical means.

During the war the Submarine Defense Association developed the so-called *colloidal fuel*, a mixture of oil and pulverized coal wherein the coal is held in suspension in the oil through the presence of a peptizing agent, called by its inventors the "fixateur." The addition of 1 per cent of "fixateur" to a mixture of 60 to 70 per cent of oil and 40 to 30 per cent of coal dust forms a sort of colloid suspension which remains homogeneous for long periods. It is claimed that this product may be used for oil-fired furnaces in about the same manner as fuel oil, and that it provides (when high-grade coal is used) a fuel of even higher calorific value per unit volume than the original oil.

Next, in particular reference to motor cars, may be mentioned the possible use of *engines of the Diesel type*. Numerous attempts have been made in this direction without noteworthy success, which has been explained by the statement that the Diesel-engine manufacturers are too busy to undertake work on the problem, while motor-car manufacturers do not know enough about Diesel engines. The use of modified Diesel engines on motor cars would relieve the situation to the extent of permitting the use of unrefined oils, instead of only such products as gasoline and kerosene.

THE USE OF OIL IN GAS MANUFACTURING

It cannot be gainsaid that the use of gas oil, a high-grade fuel oil, in the manufacture of "city gas" is a practice which is unjustifiable on the basis of resource economy. Approximately 6 per cent of our petroleum production is employed for this purpose, and the product is used for cooking and lighting by millions of people and by the industries in a number of ways. A large part of this gas is made by the use of oil to enrich blue watergas of low heating value. Recently this gas oil has become scarcer, and it is likely to become still more expensive and perhaps impossible to obtain in sufficient quantity. This condition will necessitate the use of lower grades of oil, or the production of lower grades of gas, or a change of manufacturing equipment at enormous expense. Individual gas companies cannot investigate so fundamental a question comprehensively; and individual cities or states cannot assume the responsibility of solving the problem for the entire country. The proper agency to take up this question is the Federal Government, with the co-operation of the gas companies and the oil companies and the state and municipal authorities. Such a broad and constructive study would be of high importance and would receive the concurrence of all important interests. It should include research on raw materials, manufacturing methods, and the relative usefulness of the various grades of gas that can be produced.

RESEARCH ON CHEMICAL PRODUCTS FROM CRUDE PETROLEUM

Some petroleum economists take the view that later on, when there is evidence that crude petroleum will be unable to compete with its substitutes, it will be

¹⁸On the comparative fuel values of gasoline and denatured alcohol in internal combustion engines, see Bulletin 43, Bureau of Mines.

¹⁹The substitution of petroleum for coal has gained considerable headway in the large textile and paper mills, and even in small industries in the New England section.

possible to obtain so many more valuable products from its distillates that the use of any one of these as a fuel will be condemned from the standpoint of conservation. Petroleum then will constitute the basis of a chemical products industry which will be as distinct in scope and activity as the coal-tar industry of the present time. In fact, several of the prominent refining companies have in progress investigatory work which will enable them to accumulate a reserve of technical knowledge respecting the manufacture of various chemical products from crude petroleum.

Some attention has been given to the production of drying or siccative oils from petroleum. It is claimed by the De Bataafsche Petroleum Maatschappij that an oil, the drying properties of which are comparable with those of linseed oil, may be obtained by chlorinating a mineral oil fraction of the specific gravity 0.885 at 15 deg. C., in such a manner that 1,000 l. of it absorbs 800 kg. of chlorine, and then heating the chlorinated product with the addition of zinc dust to 290 to 300 deg. C., until the chlorine has been expelled quantitatively as hydrochloric acid. The problem is to produce an oil economically which will be devoid of tackiness. Artificial resins also may be obtained by the chlorination of petroleum and its distillates; but the reduction of the time of the reaction and the purity of the products present important difficulties. The systematic study of the action of reagents on petroleum—a field which merely has been entered—will provide material for the solution of problems of this character. A subject which already has received some investigation is the conversion of chlorparaffines into esters.

A problem of constant interest is the synthetic preparation of fatty acids from petroleum and certain of its products; for when an economic process is available for the manufacture of these acids a working basis will be had for the production of edible products, some of the acids obtainable being convertible into glycerides. Considerable attention has been and is being given to the study of this problem.

The Russian naphthochemist Zelinskii has been one of the pioneers in the application of the Grignard reaction for the production of fatty acids from petroleum, and so long ago as 1902 he took out a German patent (No. 151,880) for the chlorination of certain petroleum fractions. The fraction 132-145 deg. C. of a Russian petroleum was chlorinated, treated in ethyl ether solution with magnesium and carbon dioxide, and the resulting magnesium salt decomposed with dilute sulphuric acid. An acid, $C_{18}H_{36}O_2$, was obtained which, on heating with glycerine at 250 deg. C., yielded a di-glyceride and a tri-glyceride to the extent of 60 per cent of the theoretical, according to Zelinskii. In normal times, however—that is to say at pre-war prices—this could not have competed with natural fats; but, according to reports, it was otherwise under war conditions, and it has been said that the Vereinigte Chemische Werke a. G., of Charlottenburg, Germany, was able to manufacture fat on a commercial scale by the Zelinskii process.

Chemists who have attempted to repeat Zelinskii's work have found that the yields are very small. The reasons for this are several, the principal among which are the following:

(1) The formation of the magnesium complex is very

slow with derivatives containing more than eight or ten carbon atoms.

(2) It is well known that the higher magnesium alkyl halides react with a second molecule of the original alkyl halide to give a hydrocarbon and magnesium halide; for example:

(3) Brooks has found that the halogen derivatives of petroleum hydrocarbons of ten to twenty or more carbon atoms are unstable and slowly break down on standing at room temperature to give free halogen acids and hydrocarbons which appear to be mainly saturated ring compounds.

(4) Stadnikov²¹ has demonstrated that the alkyl magnesium halide and ether complex breaks down in a variety of ways. For example, Stadnikov showed that a complex made from magnesium propyl iodide, carbon dioxide and benzhydrylbutyl ether yielded a mixture of several hydrocarbons, free carbon dioxide and mixed ethers, only a trace of acid being obtained.

Schultz in 1912-13 studied the oxidation of mineral oil fractions; but the percentage of fatty acid obtained was stated to be very small, the main oxidation products being aldehydes. Some of the best results are said to have been obtained by the oxidation of paraffine. The Chemische Fabrik Troisdorf (Drs. Hülsberg and Seiler) has patented the following method: Air or oxygen is led into a vessel containing melted paraffine, for about fifty hours, at a temperature of 100 to 120 deg. C., mercuric oxide or previously oxidized paraffine being utilized as a catalyst. It is said that the products consist partly of oleic acid and partly of volatile substances, but nothing definite has been divulged respecting the yields of oleic or other fatty acids. A somewhat similar method is that of the A. G. für Mineralölinindustrie vorm. (David Fanto & Co.), of Pardubitz, Bohemia. It has been stated that this firm has been working on a large scale, since 1915, a process which consists mainly in blowing air into paraffine for fifteen to eighteen days at a temperature of 130 to 135 deg. C. (See also English Patents Nos. 131,301, 131,302, 131,303, and 133,027.) The yield is calculated at about 60 per cent. According to reports, a fatty acid, $C_{18}H_{36}O_2$, of melting point 53.7 deg. C., thus has been obtained, together with an iso-palmitic acid, $C_{16}H_{32}O_2$, of melting point 38.4 deg. C., and lignoceric acid, $C_{24}H_{48}O_2$, of melting point 80 deg. C.

The methods so far known are considered to be of practically no value for preparing fatty acids from petroleum, even for the purpose of laboratory research. In illustration, it may be mentioned that hydrogen and fatty acids result from the fusion of the higher alcohols with potassium hydroxide, but only the higher primary alcohols give good yields. The secondary alcohols are slightly oxidized under these conditions and yield mostly condensation products, while the higher tertiary alcohols break down, giving acids having a less number of carbon atoms. Moreover, it has been shown that the alcoholates of the higher alcohols react with carbon monoxide under high pressures, but the principal products formed are esters of formic acid and not the higher fatty acids. The known methods for preparing alcohols direct from petroleum olefines yield only secondary and tertiary alcohols. And then no methods for

²⁵Cf., however, Wegryn, *Petroleum*, vol. 13, p. 24, who made entirely unsuccessful attempts to obtain fatty acids from solid paraffine.

adding halogens or halogen acids to the saturated or unsaturated hydrocarbons are known which give satisfactory yields of primary derivatives.

A variety of methods also have been proposed for oxidizing saturated and unsaturated hydrocarbons by air in the presence of various other substances and many wet methods have been tried, but in general the results are carbon dioxide, water, resinous or asphaltic material, and traces of the simple fatty acids, such as acetic, propionic, butyric, etc., which usually have not been obtained in quantities sufficient for positive identification. Our knowledge of hydrocarbon chemistry is unsatisfactory, and hence in real need of the revision of research. The commercial production of fatty acids from petroleum may some day be accomplished, but not by the methods of synthesis now known and not until there has been obtained a much more extensive and quantitative knowledge of the nature and behavior of hydrocarbons, such as constitute petroleum oils.

The lowest boiling fraction of petroleum, of the composition C_4H_{10} , may be used for the preparation of isoprene: by systematic chlorination, isomerization and liberation and addition of hydrochloric acid, the three hydrocarbons present (iso- and normal petane and tetramethylmethane) all can be converted into isoprene. But much more investigation will be required before carbon complexes.

It is thought that a simple, direct process for obtaining the butadiene hydrocarbons from petroleum soon will be found, and thus a good route to synthetic rubber will be opened up. Pyhäälä has shown that the fraction of Baku petroleum boiling between 98 and 106 deg. C. yields up to about 20 per cent of its weight of adipic acid, which, by way of the amide, can be converted into butadiene.² This method of preparation is, however, hardly possible from a commercial standpoint, and butadiene usually is obtained technically from benzene or phenol.

It is of interest to mention in this place that the emulsions obtained with the turpentine-like and other hydrocarbons of petroleum by the aid of certain emulsifying agents are similar to rubber latex and can be worked up into rubber-like products.

Finally, it may be noted that the production of dyestuffs from petroleum is an open field for research exploration. Kharitchkov³ has found that the nitro-derivatives obtained by treating machine or spindle oils with warm nitric acid (specific gravity, 1.50) are related to the nitro-compounds obtained by nitrating polynaphthenic acids and used in the preparation of dyestuffs. Nitro-products which yield with alkalis brown substantive dyestuffs and with sulphur and alkalis brown to brown-violet sulphur dyestuffs have been obtained by the nitration of the higher fractions from Galician petroleum.⁴ The preparation of aromatic hydrocarbons from fatty hydrocarbons—especially the preparation of benzene and its homologues from petroleum—requires investigation along broad lines, although the subject is not of technical interest here at present. Crude petroleum from some Bornean and Persian fields are aromatic-rich and provided toluene for TNT manufacture during the European war.

While one-fifth of the domestic consumption of petroleum is utilized as fuel, most of the crude oil is refined into products which possess wider usefulness

and higher value to society than the raw material, and refining practice is in continuous flux to adapt petroleum to a varying and widening demand. Under present technical procedure, however, petroleum yields only several hundred substances of commercial importance, but no limit can be set to the number of useful products that scientific inquiry may wrest from this raw material. Indeed, the field of petroleum byproducts represents one of the most attractive research opportunities that exist in this country today. It has been observed by Gilbert and Pogue⁵ that—

In this connection an interesting vision opens up as to how a great oil byproducts industry, through the values accruing to successive refinements of products, may be led to contribute more than it now does to the expense of petroleum production, relieving to that extent the cost distributed among the products universally used in bulk, such as gasoline. It would seem that a far-sighted economic policy, properly directed, might eventually contribute to a lowering cost for motor fuel, just as a proper shaping of coal economics could be made to relieve the focus of expense now exclusively borne by fuel coal—the two conspiring to lower the cost of living.

The time may be foreseen when, through the accomplishments of technicochemical investigation, the petroleum industry will yield a range of fuels for the internal-combustion engine only; kerosene in quantity narrowing to that desirable for country use and export trade; lubricating oils adjusted to the growing demands of mechanical power; and an ever-widening range of chemical products supporting a great petroleum byproducts industry, rivalling if not exceeding the coal-products industry in importance. In respect to the last, it should be emphasized that the United States today faces an opportunity similar to that which twenty years ago confronted both Germany and the United States as regards the manufacture of dyestuffs, explosives, fertilizers, drugs and other chemicals from the non-fuel components of coal.

THE NEED FOR PETROLEUM SECTION OF THE AMERICAN CHEMICAL SOCIETY

The recognition of the high value of science to industry has led to the adoption of systematic procedure in the collection and diffusion of technical information, and the tendency in all civilized countries is more and more in the direction of increased specialization. For example, the very comprehensive subject of chemistry no longer is represented by a unicameral society or by periodical literature dealing with it in an all-embracing manner; and while the multiplication of organizations and journals is attended with obvious disadvantages, it is recognized generally that these are offset largely by the resulting benefits, and that the interest of those engaged in any important industry can be promoted most satisfactorily by affording facilities for assembling under a distinctive banner.

The position to which the petroleum industry has attained, technically and scientifically, is such that the creation of a separate organization for the benefit of those chemists who are engaged actively in it is fully justified. In 1913 there was formed in England the Institution of Petroleum Technologists, constituted principally of chemists and chemical engineers employed in the petroleum and shale-oil industries; but so far nothing has been done, in a national way, in the United States.

The several petroleum refiners' associations afford

⁵U. S. National Museum, Bulletin 102, I, II.

ample machinery to care for questions of general policy, internal and external, affecting the petroleum industry of this country. These are, however, strictly trade organizations. Without the desire to inflict any additional cares upon the industry, which now has its hands full in supplying pressing commercial needs, opportunity is taken here to indorse the formation of a petroleum section of the American Chemical Society, a move recently proposed by a group of chemists professionally interested in petroleum and its refining.

To rest content with the present status of the petroleum industry would not be characteristic of this nation, which is justifiably proud of its initiative, resourcefulness and inventive spirit. New lifes must be developed and advances must be made in technical methods, if we are to progress adequately. No surer provision could be made for these efforts than the semi-annual gathering of the research men from the various petroleum laboratories, into the atmosphere of a great assemblage of chemists. The presentation of papers and their discussion would establish facts of value to all, broader viewpoints would be obtained, and sympathetic personal relationships formed which would stand to good advantage.

It is natural perhaps that each commercial organization should desire to retain for itself the benefits of research conducted under its auspices, yet, carried too far, it is a short-sighted policy in view of the varied workings of different minds. Community of knowledge as to scientific achievements, safeguarded by the critical discussion of experimental results, has proved to be so valuable a means of technical advancement that it should not be neglected in the petroleum industry.

The objects of a petroleum section of the American Chemical Society should be along the following general lines:

- (1) To enable chemists and technologists engaged in the petroleum, shale-oil and natural gas industries to meet and to correspond, and to accumulate trustworthy information regarding the occurrence and production of petroleum, oil-shale and natural gas, the conversion of the raw materials into manufactured products, and the characteristics and usages of these products, together with their transport and storage.
- (2) To promote the better education of persons desirous of becoming petroleum engineers, refinery engineers or hydrocarbon chemists, and to elevate the professional status of those employed in the industries mentioned by establishing a high standard of scientific and practical proficiency.
- (3) To encourage research in hydrocarbon chemistry.
- (4) To co-operate with the American Petroleum Institute and with the National Research Council, and to collaborate with the American Society for Testing Materials in its work on the standardization of bituminous and petroleum products.

PETROLEUM AND THE EUROPEAN WAR

It has been said that the success of the Allies in the European war was due largely to the supply and utilization of petroleum. Certainly, as Dunstan has remarked,¹ without mineral oil warfare would have remained in a mediæval condition and an impasse might have resulted. As we now know warfare, it is impossible to conceive of strategy and tactics deprived of oil-fired ships, motor transport, aircraft, tanks, and flame projectors, while industry at home lacked internal-combustion engine fuel and lubricants. The vital importance of the reaction of petroleum on the great struggle was pointed out clearly and forcibly at the

annual dinner of the Institution of Petroleum Technologists last year.²

The principal problems confronting the Allies were:

- (1) Whether the world could produce the aggregate supplies that were required for the service of the war.
- (2) Whether the processes of refining could be so adjusted that increased quantities of heavy fuel could be obtained as well as of gasoline, particularly of the high grade required for aviation purposes.
- (3) Whether sufficient tankers, cars and receptacles could be provided to transport and distribute by sea and land the necessary quantities of each product.

All these problems were solved satisfactorily—a fact which reflects the greatest credit to the large petroleum companies as well as to those who acted for the governments.

An enormous amount of intensive research was initiated throughout the war, and it is not too much to state that a wider and deeper knowledge of naphthology is one of the good results of the conflict. Immediately after this country entered the war the splendid facilities of the laboratories of the important refining companies and of the Bureau of Mines were offered to the War Department for experimental work, and the acceptance resulted in considerable investigational work. Perhaps the most valuable contributions were made on fuels for airplane motors, products of "cracking" processes, lubricating oils and the inspection of fuel oils. The standardization of motor gasoline and lubricating oils, and specifications therefor for Government purchase, emanated from the committee on the standardization of petroleum specifications of the Fuel Administration.

Need for Petroleum Production Engineers

The United States Bureau of Mines points out strongly the need for petroleum production engineers who shall apply their scientific and geologic training to oil field development work and to the improvement of the processes of extraction from the ground of all the recoverable oil.

One of the hard problems to contend with at the oil wells is that usually there exist strained relations between the technical and non-technical men, although there is no logical reason why most cordial relations could not be established between the petroleum engineers and the other employees. A little leniency ought to be shown on both sides. It would be a good policy for engineers to discuss with the drillers the daily well reports.

According to Bulletin 195, "Underground Conditions in Oil Fields," the duties of experienced petroleum engineers might be outlined as follows:

- (1) Keeping of records.
- (2) Preparation of data, such as production records, well logs, structure contour maps, cross-sections, etc.
- (3) Correlation of surface and underground geology.
- (4) Water problems.
- (5) Casing depths.
- (6) Underground losses.
- (7) Oil sands; location of productive sands, their thickness and quality of oil.
- (8) Well depths.
- (9) New well locations and extension of the field.
- (10) Future well production.
- (11) Gaging of oil wells.
- (12) Perforations and setting screen pipe.
- (13) Fluid levels and tubing depths.
- (14) Shooting of oil wells.
- (15) Methods of extracting more oil from the oil-bearing formations.

Physical Chemistry and Technology

Progress of Technology Dependent on Existing Physicochemical Knowledge Being Interpreted and Applied as Well as Augmented—Empirical and Scientific Solution of Problems—
Physicochemical Data—Co-operative Research

By EDWARD W. WASHBURN

THE writer has given elsewhere the following definition for the term physical chemistry: "Physical chemistry, sometimes called also theoretical or general chemistry, treats of the fundamental laws and principles and the important theories and systems of classification which have been formulated in order to give scientific expression to our knowledge of the physical and chemical behavior of material substances." Scientific expression of our knowledge of any subject is that expression of it which enables the human mind to acquire this knowledge in as complete a form as possible with a minimum expenditure of effort. Such a definition, in a sense, might be said to include the whole of both physics and chemistry and it is, of course, impossible to draw any sharp line between the two sciences or between either of them and that borderland region to which the term physical chemistry is ordinarily applied.

With such a definition of physical chemistry, it would seem almost unnecessary, if indeed not quite superfluous, to dwell upon its importance to the whole field of chemical technology, and therefore in responding to the editor's request for a contribution on this topic, I shall attempt only to set forth briefly two outstanding features of the work of the physical chemist in its relation to industrial progress.

These two features may briefly be described as follows: (1) Knowing how to find, interpret and apply existing knowledge; and (2) knowing how to set to work in a scientific manner to acquire necessary new knowledge; the term *scientific* being here employed with the significance attached to it in the definition of physical chemistry given above.

THE USE OF EXISTING SCIENTIFIC KNOWLEDGE

A good working knowledge of physical chemistry enables the industrial scientist to make use of a wealth of scientific data which would otherwise be largely unintelligible to him, the bearing of which upon his own problems he would otherwise be unable to perceive. How many chemical engineers, for example, without a working knowledge of physical chemistry would, if faced with the problem of perfecting a process for the production of pure hydrogen on a large scale, expect to find information worth considering in papers bearing such titles as "The Phase Rule Diagram of the System Iron-Oxygen," "The Electromotive Force of the Cell Zn-Saturated Solution of ZnO in NaOH-NaOH-H₂," "The Free Energy of the Reaction Between Steam and Metallic Iron," "The Free Energy of the Water Gas Reaction" or "Selective Catalysis"; or having such an expectation, how many would be able to understand and make use of the information there given? It is unquestionably possible even at the present day to publish in a scientific journal of wide circulation a contribution containing results of fundamental importance to an industry

representing investment of many millions of dollars and to have this contribution remain entirely unknown to those engaged in this industry.

During the last few years we have been hearing, and rightly so, a great deal about the importance to our national welfare of greatly increased facilities for scientific research, but in urging the importance of such research to the industrial progress of the nation we should not forget that such progress does not result from the mere acquirement of new knowledge. The acquirement must be followed by utilization. I think it may be safely stated that the amount of progress, if it could be measured, which would result during the next decade from a complete utilization by the industries of the country of the scientific knowledge already extant would be quite as great as that which will result from the new discoveries of research workers, important as the latter are sure to be. In urging, therefore, the importance of scientific research, it should be remembered that such research will promote industrial progress only in so far as industry supplies the machinery for putting the new knowledge into effect, and in so far as any industry fails to apply extant scientific knowledge, just so far are the results of future scientific research likely to be barren of practical results in that industry.

It so happens that some of the most backward of the industries in making use of modern scientific knowledge are to be found among those industries which were earliest developed by mankind, such for example, as the tanning industry, the textile industries and the glass and clay products industries, while others of this group, such as the brewing industry and metal-working industries, have made extensive use of the modern scientific methods. Such a backward condition, while deplorable from the modern scientific viewpoint, is a perfectly natural one, because the progress, in many ways remarkable, which has nevertheless been attained in these "backward" industries, represents the accumulation of centuries of hard experience, gained by the slow processes of trial and error, in many instances, long before the development of science itself. Knowledge gained in this way tends to produce extreme conservatism in those who possess it, together with a general skepticism regarding the value of anything which a chemist, who knows nothing about the industry, can accomplish. Fortunately, this condition has now largely disappeared, the last ten years having seen a great change in the attitude of many of the older industries toward the value of applied sciences.

The training of the physical chemist, including as it does (or should) the fundamentals of chemistry, physics and mathematics, as well as those of that borderland science more strictly included under the term physical chemistry itself, is peculiarly adapted to the production

of a mind trained to appreciate, understand and apply a wide range of scientific knowledge. Thus while each industry will naturally employ specialists in those branches of chemistry or physics touching most closely upon its own special field, *every* industry could to advantage make use of the services of a physical chemist, and no industrial research laboratory is complete which does not have available the services of at least one physical chemist. It is true that there are physical chemists and physical chemists and the writer knows of no safe criterion of selection other than the Biblical one, that a man should be judged by his works, and as long as there continues to be an inadequate supply of well-trained men in this field, there will inevitably be disappointments in what some of them will be able to accomplish.

The most important feature in the training of every physical chemist is the development of the reasoning powers, the powers of analysis, the ability to weigh and judge and to bring to bear upon a problem the attitude of mind and the scientific instinct of the chemist, the physicist, the mathematician, and finally, when it comes to a question of industrial application, also of the engineer. This is admittedly a large requirement, but in so far as it is attained the ideal physical chemist will be produced.

One maxim which should be impressed upon all students of physical chemistry is the following: *No one can safely use a mathematical relationship, the derivation of which he does not entirely understand.* Nor is it sufficient that he should once have understood it; the essential features of that derivation and all the factors which it involves must be kept constantly in mind. There are unfortunately in the literature numerous examples of attempts to apply some equation or law of physical chemistry to a case which does not come under it at all, or which fails to meet one or more of the assumptions upon which the law is based. In fact it is always safer to derive the desired equation for the particular case at hand rather than try to adapt a more general relation to a special case. It is because of this lack of a thorough understanding of the laws of physical chemistry that so many chemists go wrong when they attempt to apply these laws to particular cases. In fact, it is so easy to go wrong in this particular—to forget for the moment the precise significance of some term in a thermodynamic relationship, for example—that instances of this character can be found in the writings of the most eminent authorities in this field. There is, of course, no absolute guarantee of avoiding occasional mistakes of this character, but the chemist who can go back to first principles is less likely to err than the one who attempts to use a relationship in a mechanical fashion. The philosophy of science as treated by such writers as Poincaré, Mach, Enriques, Russell, etc., should be included in the education of every candidate for a doctor's degree in physical chemistry.

THE ACQUIREMENT OF NEW KNOWLEDGE

We may distinguish two classes of methods of attacking a research problem. One of these, the empirical or cut-and-try method, tries one thing after another, systematically and intelligently, it is true, in the hope that the desired solution may eventually be hit upon. The scientific method, on the other hand, first studies and analyzes the problem in the light of all the data which physics and chemistry can supply and finally outlines a method of attack which will yield as complete a knowl-

edge, both qualitative and quantitative, as may be, of the factors involved in the problem, the why and wherefore of these factors, and their relation to other associated questions, and when the solution is finally obtained there is a reasonable degree of certainty that it is the best one, everything considered.

THE EMPIRICAL SOLUTION

The first method is easier to carry out, requires the consumption of less gray matter, and has many times been productive of important results, although the percentage of successes may seem larger than it is, because the failures are usually not recorded. The first method may, moreover, yield much quicker results than the second, but on the other hand, it may never yield any results at all and if, as is sometimes the case, it is carried out on a factory scale, it may prove exceedingly expensive. If the investigator is lucky, however, he may hit upon a solution in the factory itself, and if so, he may feel well satisfied with himself, as a "practical" man, who has found a "practical" solution to a "practical" problem without wasting a lot of time and money on "highbrow stuff." The fact that he may have more or less stumbled upon a solution and that he frequently has not the ghost of an idea (or else a very wrong idea) of what was back of his problem, or why his solution was a solution, or how long it will remain a solution ought to warn him that hand-to-mouth research, even when successful, still leaves much to be desired.

THE SCIENTIFIC SOLUTION

The scientific method, while slow perhaps, is reasonably sure, its results are of permanent value and carry with them a feeling of confidence and surety which those of the empirical method largely lack. In practice, the two methods, of course, merge into each other more or less. Whenever the scientific analysis of a problem shows that little or no help is obtainable from existing scientific knowledge, recourse must naturally be had to the empirical method or else a new domain of science must be opened up and explored, and naturally few industrial problems can wait for the progress in pure science which might be required before the scientific method could be strictly employed. This was approximately the state of affairs a few years ago with respect to those industrial problems which today would be classed as problems in colloid chemistry.

PHYSICOCHEMICAL DATA

The physical chemist who undertakes to apply his science to industrial problems will often find himself confronted with the following situation: The scientific analysis of the problem is fairly easy—sometimes, in fact, ridiculously simple. The principles involved and the manner of their application are quite obvious, but when he sets to work to solve the problem he finds that the literature fails to give him the necessary physicochemical data in numerical form. A phase rule diagram is missing, the free energy of some reaction has not yet been determined, certain data on specific heats or solubility or what not are lacking. A whole set of problems in pure science is uncovered the solution of which must precede the attack on the main problem by other than an empirical procedure.

The writer was called upon recently for advice in connection with the production of a material which should be suited as perfectly as possible to withstand

certain conditions. On investigation, it was clear that the direction in which the solution of the problem was in all probability to be found could be perfectly definitely stated in approved physicochemical terms, using the letters, *a*, *b*, *c*, etc. (or α β γ , if preferred) to represent certain quantities, but that was as far as physical chemistry could go. The numerical values represented by the symbols had never been determined and although their determination offered no particular difficulty from a scientific point of view, a rather lengthy and, for the company's interest, expensive investigation would have been required. Moreover, while it was evident that such an investigation was of fundamental character to this branch of the company's activities, it was just as important and fundamental to a great many other companies engaged in the same business and it was not clear that the financial gain would be sufficient to justify the expense being borne by one company.

CO-OPERATIVE RESEARCH

It is just here on problems of this character that co-operative research needs to be developed. The resources of the universities and of endowed research foundations are not sufficient to keep the progress in pure scientific research up to the demands of the industrial world. Either the industries must themselves enter this field on an extensive scale (as some of them have already done) through co-operative research organizations, or in their own research laboratories, or they must come more strongly to the aid of universities, or preferably both. In fact, if the latter course is not pursued, they will soon destroy the possibility of entering upon the former.

Influence of Mathematical Speculations on the Progress of Chemistry

The May, 1920, issue of *Chimie et Industrie* publishes *in extenso* the lecture given by Prof. Henry Le Chatelier before the French Society of Industrial Chemistry on the great importance of applying higher mathematics to the study and interpretation of chemical reactions and on the furtherance of chemical research work.

He dwells strongly on the needs of the higher general scientific education for the chemist and cites cases where work on chemistry of the greatest industrial importance was brought to successful results not by men who had received only a purely chemical education but by those who had received a solid theoretical education in well-known engineering schools. This is illustrated by the work of men like Osmond, Deshayes, Charpy, Guillet, Bied and Taffanel, all graduates from the Paris schools of Polytechnics, Centrale or Mines, where they could not have received sufficient experimental training but where they acquired a solid scientific education which soon enabled them to become leaders in the chemical research field. If engineers could become so successful chemists, how much greater expectations might be surmised were the chemists to possess also the fundamentals of higher mathematics.

He proposes the formation of special schools of chemistry on lines similar to those of the Paris special school of electricity where only bearers of diplomas from well-recognized educational institutions shall be enrolled. Thus only will it be possible to train a growing number of men theoretically and practically well prepared to direct the chemical industries.

He suggests a program for the organization of the

staff of chemical plants. This program calls for a director who shall have the above-outlined theoretical and practical education and whose duties shall be to submit to the chief of the laboratory chemical problems and act in a consulting capacity for the solution of such problems. The chief of the laboratory shall outline and direct the laboratory work, devise the appropriate experimental methods, apportion the work among his assistants, control the exactitude of the experimental results, and interpret these results. At present there are no special schools from which men prepared for such work might be recruited. The laboratory assistants shall be experimenters in physics or chemistry, specialists in their line of work. They could be recruited in a satisfactory manner from the now existing schools of chemistry. The help for doing the more or less routine work could be recruited from those with some easily acquired experience in the required line of work.

Prof. Le Chatelier considers the problem of training men for the task of chief of a laboratory of prime importance and dwells especially on their need for quite a thorough knowledge of special mathematics. He illustrates with facts the application of the notion of continuity to the interpretation of the theory of solubility, the utilization of geometric representations especially for the outline of programs of experimental work, the generalization in solving chemical problems by the use of logarithms and a better co-ordination of experimental results and minimizing the experimental errors by applying the fundamentals of the calculus of probabilities.

It is especially in the practical application of chemical mechanics that mathematical knowledge is of great importance. All the laws of chemical mechanics are exclusively of mathematical origin. The number of these laws is small, but their rigorous exactitude makes them particularly useful. He passes them in review and illustrates their importance by enumerating some of their applications. Thus:

The law of factors of equilibrium has served to explain the function of catalyzers in chemistry as being similar to that of lubricating oils in mechanical apparatus.

The law that two systems in equilibrium with a third are in equilibrium with each other and reciprocally has been successfully applied by van't Hoff to the study of the vapor tension of efflorescent salts.

The law of the stability of equilibrium has been used in solving the problems of a better utilization of the sensible heat of gases and is applied to the now rapidly growing industry of synthetic ammonia.

The law of phases has enabled van't Hoff, Bakkhuis, Roozeboom and their pupils to solve the complicated systems of acid solutions of iron chlorides and of the sea water salt solutions. The same law led van't Hoff to establish his dilatometric method to the solution of chemical problems.

The law of iso-equilibrium established by Clapeyron in the particular simple case of vapor tension has been generalized by Thompson to fusion phenomena. This law, combined with the law of mass action of gaseous systems, has been successfully applied to the synthesis of nitric acid by the electric arc.

He concluded with the plea for changes in the educational programs of colleges and universities and for the formation of special schools of chemistry for the theoretical and practical training of chief chemists and chiefs of chemical laboratories.

Relation of Chemical Engineering to Sewage and Trade Waste Treatment

A Brief Outline of the Methods of Sewage and Trade Waste Treatment—The Activated Sludge Process and the Chemical Engineering Problem Involved in Pressing and Drying the Sludge

By R. H. EAGLES*

THE development of municipal sewage disposal in the United States has made great strides in the past decade by virtue of the progressive and forward-looking spirit of our fast-growing cities. Impetus has been given to the movement by the natural influence of the many public welfare campaigns for which this country is distinguished.

In Great Britain and Continental Europe, where residential and industrial habitation is extremely dense, adequate sewage disposal equipment is a universal necessity, because the public waterways—the natural scavengers—cannot stand the concentrated load of raw sewage which they must otherwise carry.

American engineers are anticipating this condition and are devoting their energies to the development of a standardized system or systems which can be applied to any set of local conditions with pre-assured success. The matter of operating expense is in most cases the governing factor, and this has given rise to many efforts to recover commercially the valuable elements which are known to be present in the wastes. Attempts along the latter line have been only partly successful to date in that the valuable constituents have been reclaimed in concentrated form as solids, but the final economical preparation, in marketable form, has proved the stumbling block.

It is toward the solution of this problem, which is in reality of a process nature, that the services of the chemical engineer should be impressed. He alone of the engineering profession is best adapted by training and experience to work out the details which involve principles of physical chemistry and the mechanics of pressing, conveying and drying. He is also well equipped to prepare his product in the best shape—chemically and physically—to assure its ready demand and highest value.

METHODS OF SEWAGE TREATMENT

To be specific, one of the most important problems facing sewage treatment development today is to find a satisfactory means of dewatering and drying activated sludge and converting it into a marketable fertilizer. Before elaborating on this problem a brief sketch of sewage treatment methods may be of interest.

When the disposition of domestic wastes by water carriage came into general use it immediately presented the problem of reseparatoring the waste materials from the water at a community or municipal plant. This became necessary for the protection of public health from drinking water pollution and for

aesthetic reasons involving the visible evidence of wastes in the public waterways. In the case of towns and cities located on the seacoast the simplest method, and one which is still generally in use, lay in carrying the wastes into the sea, where the extremely high dilution soon obliterates all traces of pollution.

The objectionable constituents of domestic sewage consist chiefly of unstable organic compounds in solution and suspension. The compounds undergo more or less rapid decomposition and furnish nuclei for the propagation and subsistence of disease-producing bacteria which are also present.

Among the methods of sewage treatment which have been used, either alone or in combination, are the following:

1. Mechanical Fine Screening.
2. Sedimentation.
 - (a) Straight sedimentation with sludge removal.
 - (b) Imhoff sedimentation, with self-contained sludge digestion.
 - (c) Septic tank sedimentation with self-contained sludge digestion.
3. Chemical precipitation (followed by sedimentation).
4. Sand filtration.
5. "Sprinkler" or "trickling"—aerating filters.
6. Contact beds.
7. Chlorination.
8. Electrolytic oxidation.
9. Activated sludge.

The various features and combinations which apply to these methods are too numerous to describe, but it is the purpose of this paper to present some of the features which may be of active interest to the chemical profession.

THE ACTIVATED SLUDGE PROCESS

The activated sludge process of sewage disposal has come into prominence within the last few years. It employs the use of aerobic, or oxygen-consuming, bacteria for the purification of the sewage. The biologic growth is first developed and cultivated, and it then propagates and is kept alive by the constant addition of fresh sewage, the impurities of which supply the food, and air, which is used both for agitation and as a supplementary food. This method has proved highly satisfactory as regards the production of a clear, stable effluent, and it has reduced in many cases a sludge containing considerable fertilizer value in the form of nitrogen compounds. The control of the bacteria and the means of increasing their nitrogen-retaining ability extend into the field of chemistry.

Another phase of the activated sludge process

*Chief of Industrial Section, Sanitary Engineering Department, Dorr Company, New York.

which should receive the attention and study of chemical engineers is the design of apparatus which will economically introduce the air and maintain a prolonged, intimate contact with the fresh sewage and the bacterial flocs. The greatest cost of the process is that of supplying compressed air. Many experimenters have relied too much on the use of the air to effect agitation and circulation, in addition to supplying the really minute oxygen requirement of the bacteria.

It has been calculated that the actual oxygen requirement could be theoretically satisfied by the addi-

CLARIFYING TEXTILE MILL WASTE WATERS AND REMOVING THE IMPURITIES AFTER CHEMICAL PRECIPITATION AND COAGULATION

tion of 0.05 cu.ft. of air per gal. of sewage treated. The average optimum practice of a number of experimental stations in this country and England has shown a requirement of 1.5 cu.ft. per gal., or thirty times theoretical.

A more recent modification developed at a test plant at Mount Vernon, N. Y., has reduced this requirement to 0.5 cu.ft. per gal., one-third the usual amount, but still ten times theoretical. The reduction at this plant is due partly to a mechanical design which insures prolonged and intimate contact of the air bubbles with the sewage, at the same time utilizing the maximum mechanical efficiency of the air for circulation purposes.

Here again is an inviting field for chemical engineering research. It is, strictly speaking, the problem of absorption of a gas in a liquid, the elements being air and sewage.

This leads to a closely allied feature of the process which has not yet been perfected—namely, the matter of air diffusion. Various types of porous media such as filtros tile, basswood blocks, cement and sand preparations have been tried with varying degrees of success, the desideratum being an air bubble of sufficient fineness to prevent its coalescing because the minute bubbles offer more contact surface. Practice in this country has inclined to the use of filtros tile as the best-adapted medium, but it is an open question whether ejectors or some type of spraying device may not economically substitute for diffusion media entirely.

By far the most important problem in connection with the activated sludge process, as mentioned before, is the disposition of the resulting sludge. The activated sludge itself is a biologic growth of flocculent structure, and under proper conditions should contain from 3 to 6 per cent nitrogen on dry basis, expressed as ammonia. In view of the present market

price and demand for nitrogen fertilizer it is readily seen that a promising field of investigation is opened up in the commercial reclamation of the sludge.

PROBLEMS OF PRESSING AND DRYING THE SLUDGE

The flocculent nature of the sludge prevents its concentration by straight sedimentation, although it can be reduced to 97 per cent moisture by mechanical dewatering devices, as has been demonstrated by the use of a Dorr Sewage Clarifier at the Milwaukee test plant. Centrifuging will further reduce the water content by approximately 90 per cent, but the definite advantage to be obtained by this expensive intermediate step has not yet been demonstrated. The use of filter presses of various types has been tried with mediocre success. The sludge flocs on pressing revert to a jelly-like mass which clogs the pores of the filter cloth, resulting in an expensive and inefficient procedure. The sludge decomposes rapidly to an unfilterable mass, and this factor must be carefully watched.

Various experimenters have been using filter presses even under the trying conditions and producing a filter cake with moisture content sufficiently reduced to permit of feeding to a drier. Mechanical conveyor difficulties have been encountered, and an appropriate drier has not yet been determined.

It may be said without exaggeration that further development of this very desirable method of sewage purification will be held at a standstill pending a successful method of pressing and drying the sludge. It is not unreasonable to expect that helpful suggestions, and possibly a successful solution of the prob-

TANNERY SEWAGE CLARIFIER IN OPERATION, REPLACING AN OLD "FILL AND DRAW" SYSTEM

lem, will come from the chemical engineering profession, where similar problems have been encountered and solved.

SEDIMENTATION

The foregoing will serve to point out the immediate problems of the activated sludge method of sewage treatment. Another distinct system of treatment which is coming into prominence, particularly in England, is the use of straight sedimentation for the removal of all solids which will settle, followed by treatment of the clarified sewage by biologic or chemical final purification. The settled solids are removed in the form of thick sludge for disposal by biologic diges-

tion or by natural draining and carting-away methods. This system offers the advantage of low operating costs, but does not offer the recovery values of the activated sludge process because the nitrogen values must finally be carried away in solution, preferably as innocuous nitrates.

A careful study of sedimentation principles is entailed by this system, which may be said to lie within the field of physical chemistry. The mechanics of

TANNERY SEWAGE CLARIFIER (UNDER CONSTRUCTION)
CLOSE TO RESIDENCES. NO FLIES, ODORS OR OTHER
NUISANCE RESULTS FROM ITS OPERATION

performing efficient sedimentation and provision for continuous withdrawal of thick sludge are features of great importance.

Sewage treatment by chemical precipitation has been used in many localities, the reagents usually being lime or lime and copperas. The method entails a high operating expense, with slight prospects of recovery values, and cannot be said to possess attractive possibilities. The use of chlorine gas, however, for disinfection of the final clarified effluent is common practice and is satisfactory in meeting certain local conditions.

TREATMENT OF TRADE WASTE

The field of industrial trade waste treatment is replete with possibilities which should attract the attention of chemical engineers. Broadly speaking, all methods of industrial waste water treatment are dependent on definite chemical reaction, or on the close delineation of physical chemical conditions. A number of unsuccessful trade waste treatment plants can be pointed out where the failure is directly traceable to the fact that an attempt was made to apply one of the standard methods of domestic sewage treatment to the problem, in contravention to basic chemical principles. The field belongs rightfully to chemical engineers, who can trace the offending elements in the waste waters back to their source and can regulate the other wastes or prescribe chemical additions to react with the offending elements or convert them into a physical state suitable for separation from the innocuous waters.

It would be difficult to describe standard methods of trade waste treatment because they will vary widely with local conditions at different plants even in the same industry. In general the following will apply:

- (a) Sizable suspended solids—removed by screening or sedimentation.
- (b) Colloidal solids—removed by addition of chemi-

cal coagulants and electrolytes, followed by sedimentation.

- (c) Dissolved solids—removed by chemical precipitation, followed by sedimentation.

- (d) Color, odor—removed by chemical precipitation, or sand filtration, etc.

Trade waste treatment naturally involves a constant overhead expense to the manufacturer without material gain except in cases where byproducts can be recovered. It is therefore essential that operating costs be reduced to a minimum, and this can be accomplished only by the careful study of the chemistry of the plant itself with a view to bringing into use every potential coagulant which might otherwise be thrown away without utilization, and the regulation of the internal plant routine to make the waste water conditions as uniform as possible. It also means a careful survey of the pollution conditions to ascertain the minimum degree of purification which will suffice.

The mechanical methods of dosing waste waters, the design of adequate sedimentation units to produce uniform clarification and a minimum volume of sludge, the use of carefully determined chemicals where necessary, are all essential factors which tend to make the field of trade waste treatment a distinct profession, merging the experience of the chemical and sanitary engineers.

With the close of the war has come a renewed siege of anti-pollution campaigns on the part of the various health authorities. These campaigns are doubtless justified where an economical system of overcoming the pollution evil can be offered. All public-spirited citizens will welcome the restoration of our rivers and waterways to their original clean condition because they are the natural parks and playgrounds of the populace at large. If they can be cleaned up without placing an excessive burden on the industry, which also has a right to exist, all energies should be bent to that end.

It is apparent that the chemical engineer has a definite interest in matters pertaining to sewage and trade waste treatment, and it is to be hoped that this interest will soon manifest itself in distinct contributions to the art as now practiced.

New York City.

Purification of Sewage With Activated Sludge

Activated sludge has the property of purifying raw sewage in the presence of air and it is generally admitted that this remarkable purifying action is exercised according to the mechanism of nitric fermentation. R. Cambier has studied this subject and presented the results of his work before the French Academy of Sciences (*Comptes rendus*, March 15, 1920, pp. 681-684). He subjected raw sewage in the presence of activated sludge to forced aëration at temperatures between 0 and 55 deg. C. and found that the most appropriate working temperature is between 20 and 25 deg. C., that the presence of nitrous acid is not appreciably manifested below 30 deg. C. and that activated sludges are capable of transforming nitrites into nitrates at ordinary temperature. If a mixture of activated sludge and sewage after nitrification is left to settle for three hours and the supernatant clarified liquid decanted, the liquid separated from the centrifuged residue is found to be poor in nitrates but containing 10 mg. of ammonia per liter and that the nitrifying capacity of the sludge is not altered.

Putting the Vegetable Oil Industry on a Scientific Basis

An Outline of the Vegetable Oil and Fat Industry in Which Attention Is Directed to Problems Connected With the Production of Crude Oils and Fats, Laboratory and Refining Problems, and Research Opportunities in Manufactured Products

By HERBERT S. BAILEY*

UNTIL comparatively recent times we have been accustomed to look upon certain fats and oils as suitable only for technical purposes, while others were classed as edible. This distinction was to a certain extent geographical. The Russians, for instance, used linseed and sunflower seed oils for food, while in England and America these were of importance only in the paint and allied industries. The Eskimo dines daily on whale blubber and the African soaks his food in palm oil, but in the countries of the temperate zone whale oil has been associated with insecticidal sprays, and palm oil with tinplate manufacture.

With the recent developments in the art of refining, deodorizing and hydrogenating, these sharp lines of demarkation between edible and technical oils have largely disappeared. There are of course a few oils, such as castor, which are still taboo in civilized kitchens, and the sad lesson which Germany learned just before the war, when the poisonous hydriocarpus oil or Marotti fat was used in margarines, has made us hesitant about using new products in foods. Hydrogenated whale oil is today a regular constituent of some of the Continental butter substitutes and the writer has seen samples of fish oils which were as sweet and palatable as any of the commonly accepted edible vegetable oils.

The fact that nearly all fats and oils can be made edible does not mean, however, that they are now or will be in the near future employed promiscuously in food products. There are at least three basic reasons why some oils will remain in the technical group. One of these is psychological, one chemical and the third economic.

In the edible oil trade the conservatism of the non-scientific men at least is marked and it is more difficult to bring about a change in raw material even than in plant practice. Naturally, also, few manufacturers of food products care to risk the effect of the prejudice which would appear toward their goods if it were known that they were putting fish oil or horse tallow into their wares.

Because of their peculiar chemical composition, oils with good drying properties, like linseed, perilla and tung, are naturally more valuable to the paint maker than the lard substitute producer. Similarly the medicinal oils, such as cod liver, chaulmoogra and castor, will be used largely by physicians, but because of the comparatively small demand of this trade, where the production is large the excess will go into technical lines.

Economically it is not profitable to subject some oils to the high refining necessary to convert them into satisfactory food products. Until the relative values of the fats and oils classed as technical and those at present used as food change, there is little prospect of any radical departure from the present grouping.

There was during the recent apparent shortage of

oils a considerable volume of interesting and more or less valuable research on the utilization of well-known oils for new purposes and of little-known materials as sources of new oils. In these reconstruction days, however, the most fertile field of investigation is in improving the old or devising better new methods for the treatment of our common oils for the purposes for which they are already used. This will be especially true of oils such as soya bean and whale, which are on the border line between the technical and food groups, not quite the equal of linseed for paints or of cottonseed for lard substitutes.

The Scope of the Fat and Oil Industry

The various divisions of the fat and oil industry are so numerous that no single research laboratory, much less an individual investigator, can hope to cover them all. Dividing the field along the lines of the successive steps followed in obtaining the finished products from the raw oleaginous materials, we may start with the four main divisions:

- A. Methods for obtaining crude oils from raw materials.
- B. Subsequent treatment of the crude products.
- C. The manufacture of derived products.
- D. The utilization of byproducts.

Under the first of these headings will fall the various procedures for separating oil or fat from substances in which they occur in nature. At present there are but three methods of any consequence: Boiling out with steam; pressing out with hydraulic or torsional pressure; extraction with volatile solvents.

REFINING OPERATIONS

Having obtained the crude oils, it is necessary to subject them to one or more of the following treatments before they are suitable for human consumption:

1. Washing, filtering or settling, as applied to the virgin oils such as olive and peanut.
2. Refining with an alkali or acid.
3. Bleaching with an absorptive material such as fullers earth or carbons, or by chemical agents.
4. Deodorizing.

Technical oils usually require some sort of purification before they go into the finished products; thus, for paint and varnish making, linseed oil is settled or filtered to remove the mucilaginous materials, and bleached if intended for especially light colored products.

DERIVED PRODUCTS

Under the head of derived products might properly be discussed research related to the manufacture of boiled and bodied oils; lubricating greases, soaps, linoleum, rubber substitutes, stuffing grease; leather dressings, patent and artificial leathers, and many other lines in which fats and oils are used. Of perhaps more

*Editor, Chemists' Section, Cotton Oil Press.

general interest are the manufactured food products, lard and butter substitutes and the so-called synthetic milks. In these industries there are various steps between the crude materials and the finished articles of commerce, but only a few of the more obvious research problems in this field will be suggested in this article.

Problems Connected With the Production of Crude Oils and Fats

STEAM OR WATER EXTRACTION

One of the primitive methods of obtaining oil is that of merely boiling the oleaginous raw material with water. This process is still used by the natives of the tropics in making their "chow" oil from the fleshy portion of the palm fruit. A modern adaptation of this process is found in our packing houses, where the fats are removed from animal tissues by steaming in tanks under pressure. That there is a possibility of increas-

A PRIMITIVE OLIVE OIL MILL

ing the efficiency of the present practice or improving the quality of the resulting fats is doubtless true, but these problems after comparatively little preliminary laboratory work would best be handled in the plant.

EXTRACTION WITH PRESSURE

By far the larger part of our vegetable oils and a proportion of the animal fats are obtained by pressing, usually hot, the finely ground seeds or tissues containing them. The opportunities for the research chemist in this field are more limited than for the oil technologist who has mechanical genius, nevertheless there is still room for the chemical laboratory to be of great assistance to the crude oil mill. The time is coming when oil seeds will be purchased on the basis of their oil and food value, and the lucky chemist who devises a simple, rapid and yet reliable method for determining the oil content of the crude mill grist will win for himself a place beside Babcock, who did so much for the dairy industry. That a chemical treatment of some of the oil seeds may materially facilitate the pressing of the oil from them is probable—in fact, one such process has already been patented. Another problem for the laboratory is the process of fixing or, better, destroying the color bodies in the meals before they are pressed, thereby reducing materially the subsequent losses which now occur in the refining process.

EXTRACTION WITH VOLATILE SOLVENT

It is in the extraction of oils and fats by means of volatile solvents that we find some of the most promising problems for the research chemist and oil technologist. While much work on extraction processes and

suitable solvents has already been done, it is surprising how little reliable information is available in the literature. The chief objections to extraction systems at the present time are: The commonly supposed fire hazard, accompanied as it is by increased insurance rates; the loss of solvent in its removal from the oil and percolator residue; and the character of the products obtained.

To decrease the fire risk, it has been proposed to use di- or tri-chlorethylene, chloroform, or other non-flammable solvents, and there is still opportunity for investigators to find extraction liquids which will have all the advantages of benzene and gasoline without their disadvantages.

RESEARCH MUST BE CARRIED TO SEMI-COMMERCIAL STAGE

The points which must be borne in mind in such research are not only the power of the solvent to extract the fat or oil but the ease with which the solvent can be completely eliminated from the extract and spent meal and, what is often overlooked, the quality of the extract. Some solvents which in the laboratory in glass vessels have appeared very promising, when used in iron percolators on a large scale have been most disappointing. The meal in the plant equipment either packed so that it would not percolate or if extracted in tanks provided with agitators could not be properly mixed with the solvent. Again in some instances the meal, which on an experimental scale worked beautifully, when treated in 10-ton lots extracted so slowly or held the solvent so tenaciously that the operating department turned down the whole extraction proposition and "cussed" out the research laboratory as a lot of academic theorists.

One may obtain an oil—from cottonseed for instance—with some solvents, in glass flasks, which refines and bleaches with entire satisfaction, but the "stuff" turned out on a plant scale by an apparently identical procedure either will not refine at all or the losses more than counterbalance any advantages to be gained by extraction instead of pressing. These past failures, however, should not discourage further research but rather stimulate it and be a warning to those in charge of such investigation to fully test their discoveries on a semi-works scale before risking them in a full commercial trial. We shall have more to say about this point later.

DOES OIL EXTRACTION DIFFER FROM INORGANIC LEACHING?

A fundamental knowledge of the process of extraction is highly desirable at the present time. The commonly accepted view seems to be that there is a radical difference between leaching out an oil from the more or less completely ruptured tissues in which it occurs and the washing of an inorganic precipitate free from a soluble salt. Is this actually the case or do the same laws which have been found applicable to the inorganic leaching processes hold equally in the extraction of plant and animal constituents with solvents? This is a basic problem and one which might well be given serious study by some of the research laboratories of our universities. If we knew how to calculate the optimum conditions of pressure, temperature, size of particles and extent of draining in each percolation, from the solubility of the pure oil in the solvent at different temperatures and pressures, much of the present cut-and-try so-called research on this problem could be relegated to the "tank house."

Laboratory and Refining Problems

In a broad sense the term refining may be used to cover all those processes for the removal of free fatty acid, color, odor and other objectionable qualities from crude oils usually under the supervision of the refinery superintendent. Here we are dealing largely with strictly chemical or physical processes, therefore in this branch of the fat and oil industry the laboratory finds a most fertile field for research. The application of scientific knowledge to oil-refining is now woefully small, but the bearing which recent discoveries in the realms of colloids and catalyzers has to the operations is realized by many of our chemists and we may confidently expect some most important applications of this knowledge in the near future.

REFINING PROCESSES

Taking up the various refining processes, we find, first, the washing and clarifying of those glycerides which nature has given to us in a condition for use without chemical treatment. Aside from the biochemical problems of keeping the fat- or oil-bearing tissues sweet and free from any decomposition so that their products will be neutral and devoid of objectionable odors, there is little obvious opportunity here for investigations of a scientific character. However, in the preservation of such perishable materials as copra and fish refuse, which are usually allowed to decompose partly before being pressed, there is a chance for some valuable research work. That coconut oil can be made from properly prepared copra or even the fresh undried fruit so sweet and palatable that it requires no subsequent treatment has already been demonstrated. The cod liver oil obtained from sound livers is also said to be superior to any of the so-called refined oils, and doubtless in the pressing of olive oil, the premier of virgin oils, there is some opportunity for scientific study.

Oil refining in the restricted sense—the removal of free fatty acids and some color by treatment with chemicals—is doubtless receiving more attention from the research organizations of the industry than any other single phase of their activities. This is due partly to the realization by the refinery of their inability to obtain even under apparently identical conditions the same results with any two batches of oil in the plant kettles. Also the knowledge that about half the loss in refining is the result of saponification and occlusion of neutral oil makes it desirable to find as quickly as possible means for overcoming these difficulties.

DECOLORIZING AND NEUTRALIZING

With most crude oils the refining process has a two-fold object, the neutralization of the free fatty acid and the removal of a part of the coloring matter. To accomplish this, alkali, usually caustic soda solution, is mixed with the crude and the soap thus formed is separated from the refined oil. There are many individual phases of the process which will bear considerable further investigation, but they are all comprehended in the study of the interrelation of temperature, strength of refining alkali and excess of alkali over that needed to neutralize the free fatty acids. The separate factors have all been studied many times both in the works laboratories and the refineries, but apparently we are still a long way from having any definite conception of the fundamental chemical and physical principles underlying the entire process. Probably the colloid chemist

can best solve these problems, as at least a part of the coloring matter is a colloidal suspension in the oil, and obviously where it is a question of separation of soap from occluded oil a knowledge of the behavior of colloids will be very helpful.

Another angle from which to attack the refining problem is a search for reagents which will destroy or remove the color of the crude oil without injuring it. Perhaps more important is the neutralization of fatty acids without saponifying the neutral oil. We know that boric acid will coagulate some of the color bodies of crude cottonseed oil and that carbonates do not saponify glycerides as easily as caustic alkalis, but so far no one has devised or at least not divulged a commercially practical scheme for taking advantage of these facts.

BLEACHING WITH FULLERS EARTH AND CHAR

Passing on to the next refining operation, that of bleaching, which is now usually effected in the edible oil trade by means of fullers earth, and in the paint and varnish business by merely heating or by subjecting the oil to the action of the ultra-violet light, we find another most promising field for investigation. The work of the Chemical Warfare Service on carbons for gas masks has stimulated the search for a char which would be so superior to fullers earth that it would pay to use it even if it were more expensive. Unfortunately some of the work on bleaching chars has been undertaken without a full realization of the fact that their action is specific. Investigators have taken carbons which were found especially valuable for gas masks and been surprised when they proved useless for the bleaching of oils. Some manufacturers of carbons do not hesitate to recommend their wares for removing the color from soya bean oil because they have proved satisfactory in bleaching glycerine or sugar house products. It is not at all unlikely that the selective decolorizing effect of carbon may be so specific that different oils will require different chars for the best results. Since many of the common oils contain more than one chromogenic body, in some instances a mixture of different carbons and fullers earths may bleach better than any single material. So far we have little scientific basis for any workable theory of the bleaching effect of absorptive materials. It is simply a question of trying out on each oil as many chars or earths as are available. Such tests, of course, should be made under different conditions of temperature and time and the loss of oil due to absorption determined in each experiment. Research of this type, however, while sometimes of more monetary value, will never deserve the recognition due to that which has for its ultimate goal the determination of the laws which underlie these processes.

CAUSES OF OBJECTIONABLE ODORS AND FLAVORS UNKNOWN

The last step in the making of edible oils is the removal of objectionable odors and flavors by deodorization. This is in principle simply steam distillation of those substances which impart to the oil a disagreeable or too pronounced flavor. We say those substances which give the oil flavor, because we know practically nothing about what they are, or whether they exist at all in the oil as it occurs in nature. Whether there are many or few organoleptic bodies in a single oil and whether any of these are common to a number of oils is still a mystery. In fact, all we do know is

that if an oil is blown under vacuum with superheated steam, free acids, if present, and other substances, some of which give an aldehyde reaction, are carried off and the remaining oil is nearly tasteless and odorless. The practical results of the process are very satisfactory, except that in time the objectionable flavor may return, and in some instances steamed oils are more "tender"—that is, spoil more readily—than those which have not been so treated. It would seem that while there is undoubtedly opportunity to discover new and improve old deodorizing methods, the most interesting problem here is the identification of the flavors of the common vegetable oils.

CLARIFYING TECHNICAL OILS

The technical oils as a rule require some clarification and often bleaching before they are suitable for use. In the paint and varnish trade the principal oil, linseed, is usually "tanked" for a time to allow the separation of the albuminous matter. Attempts, some of them quite successful, have been made to hasten the process by the use of centrifugal separators or special heat treatments. Since this mucilagenous matter is in a very finely divided if not actually colloidal state, it is probable that the colloid chemist can help materially in finding means of expeditiously coagulating and getting rid of it. At any rate there is a real problem here that is deserving of someone's attention. The man who tackles this research will deserve the gratitude of the paint chemist if while he is devising means for removing this so-called "foots" he will find out what it is and why even a very small amount of it will ruin paint.

BLEACHING TECHNICAL OILS

To obtain a light-colored linseed oil, it is often merely necessary to heat it to the proper temperature and a similar change takes place with many soya bean oils,

MODERN OLIVE OIL PLANT

Left, filling cloths. Center, forming cheeses. Right, pressing cakes.

but every little while one meets with an oil which does not respond to the heat treatment. What is it that causes this difference between two samples which so far as the chemist can tell by his analysis are identical? Also is there any simple method to remove the color substance, apparently present in some oils and not in others, that darkens instead of bleaches when heated?

At one time sunlight was used by at least one of our large American castor oil producers to bleach his

off-colored oils, and of course this is still common practice with yellow palm oil and many waxes. Recently the ultra-violet light has been suggested and we are informed is actually used on a commercial scale for bleaching linseed oil. That its use may be extended to other oils is possible and of sufficient promise to warrant considerable research.

Chemical bleaches, such as acid bichromate, have been successfully employed with technical and even food oils, and there is no reason to believe that other reagents not yet studied might not be considerably more satisfactory than any of the present processes.

Research Connected With Manufactured Products

ACTION OF DRIERS

During the recent high prices for linseed oil the possibility of using cheaper substitutes received considerable attention. This led to a greater interest in the semi-drying oils and driers in general. Important advances have been made in the last decade in the use of driers and some valuable scientific work has been done on the chemical reactions taking place during the drying of oils, but the question of how and why some metallic salts make an oil in which they have been dissolved dry to an elastic film has not yet been fully answered. There is a generally accepted belief among paint and varnish makers that a mixture of manganese and lead driers is better for linseed paints than either one alone. We also know that with soya bean oil cobalt salts give better results than lead and manganese. There are, however, several metals—for instance, vanadium and titanium—which have not yet been properly investigated.

A still more interesting set of problems in the field of driers leads into the study of optimum conditions under which to add the metallic salts to the oils. It is generally believed that it is the metal irrespective of the acid radical with which it is coupled that causes the oil to take on oxygen, but many paint and varnish makers still persist in using the difficult soluble substances, such as "shot manganese," instead of the acetate or fatty acid soaps. Apparently the temperature at which the drier is added to the oil and especially the heating or blowing the oil has received preceding the addition of the drier affects the quality of the finished boiled oil. Under some conditions the oil will dry with satisfactory speed but to a tender, cheesy film, and much is still to be learned about all these points. This rather superficial discussion of the drying oil problem will, it is hoped, suggest some lines of research which may lead to interesting and valuable studies.

CHINA-WOOD OIL

Tung or china-wood oil, that freak among drying oils, is of itself worthy of further investigation, although already much has been learned about its behavior toward heat and driers. The varnish maker knows that he must heat this oil just as near the jelling point as possible, to make it blend properly in the varnish, but he has no means, except the rule-of-thumb "string catching" of it to tell when this point has been reached. There are two possible ways in which the research laboratory can save him many gallons of jellied or undercooked oil, one by giving him definite directions as to how long and at what temperature he should heat each lot, and the other by discovering some process by which tung oil can be properly polymerized without the danger of setting it into an insoluble jell. This latter

is much the more promising, as there is such a difference in the behavior of different lots of tung oil that there is little chance of controlling the boiling process better than it is at present by the knowledge of a skilled varnish maker.

POLYMERIZATION BY BLOWING AND HEATING

Blown and heavy bodied oils are, it is supposed, polymerized glycerides, but they are usually made by blowing the raw or refined oils with air at a more or less elevated temperature. That many oils can be polymerized by heating them out of contact with any appreciable amount of oxygen has been proved by carrying on the operation in nearly full sealed tubes. It is also known that by a combination of heating and blowing simultaneously or successively at different temperatures a great variety of products can be obtained from the same oil, but very little study has been given to the chemistry of these processes.

RUBBER SUBSTITUTES—LUBRICATING GREASES

By two or three American manufacturers of rubber substitutes much valuable research has been done on the vulcanizing as well as on the polymerization of oils, and the quality of some of their products would indicate that with just a little more study products of great commercial value in the rubber trade might be produced.

Recent work on the relation of colloids and jells to lubricating greases and soap has opened up a splendid field for a number of investigations, many of which will have a direct application to these industries. In England last year the "germ theory" of lubrication was brought out, and while some of the articles on it sound a bit more commercial than scientific, the fact that fatty acids have a surprising effect on the interfacial tension between mineral oils and aqueous solutions makes the "theory" worthy of further study. If glycerides or fatty acids can be proved to impart to mineral oils valuable lubricating properties which they alone do not possess, the demand for castor, rape and lard oils, and horse and other tallows in lubricants may be materially increased.

ARTIFICIAL AND PATENT LEATHER—LARD COMPOUNDS

In the artificial and patent leather factories and, in fact, wherever nitrocellulose solutions are used or blown oil coatings are applied to flexible backings one will not have to search far to find both practical and theoretical research problems. In these fields again the materials with which we are dealing are probably in a colloidal condition, and a working knowledge of this phase of chemistry will be of great assistance to the investigator.

Turning now from the technical field to human foods, we come first to the production of lard substitutes. This industry consumes today in the United States just about half of the total vegetable oil produced in the country. Obviously, therefore, improved methods for decreasing the cost of manufacture or improving the quality of lard substitutes are of vital importance.

The processes for making lard substitutes, or "compounds" as they are commonly called, have reached a high degree of perfection and many of the brands on the market are at least equal if not superior to hog lard, but there is still plenty of opportunity for high-class research in this branch of the industry. The use of hardened vegetable oils in compounds is now common practice and food chemists would be disappointed if

they did not find at about this point in the discussion mention of hydrogenation.

Although this process of making hard fats from liquid oils has been a favorite hunting ground for chemists and patent lawyers in recent years, none of the present processes is perfect, except on the patent side perhaps. The complete removal of the catalyzer, metallic or colloidal nickel, from the hardened oil is troublesome at times, and it is doubtful if more than a few of the hydrogenators know how to get the maximum hardening effect with the minimum expenditure of time, heat and labor. It is also within the realm of possibility that a catalyst cheaper and better than any of those at present in use will be discovered.

To many manufacturers the phrase "continuous process" has a very pleasant sound, and if a really satisfactory continuous hardening process is perfected to replace the present batch processes, chemists will undoubtedly share the honors with the mechanical engineers. In addition to the conversion of the unsaturated glycerides into hard saturated ones, there is every reason to believe that with the proper choice of a catalyzer and operating conditions it will be practical to transform the flavor and color bodies of some oils into unobjectionable substances.

Aside from the flavor in compounds, which depends on the fats and oils used in making them, the most important qualities are color and consistency. The exact determination of these characteristics is at present impossible, and an interesting piece of research is to be found in devising methods for evaluating these properties. Of more immediate monetary value would be a method for predetermining from an analysis of the components used in making a batch of lard substitutes the color and especially the melting point of the finished product. Since the snowy whiteness and to a large extent the creamy consistency of the compound as marketed is the result of whipping air into the chilled

A SEMI-WORKS OIL EXPELLER

mixture of fats, it is of interest to know what effect, if any, this air has on the keeping qualities. One of the very common objections to lard substitutes is their tendency to become streaky or opalescent in spots. This is commonly ascribed to improper closing of the package and apparently is connected in some way with the gradual escape of the incorporated air. When once melted and allowed to cool again slowly, compounds usually separate into a mush, of crystals and more or less liquid oleans. Hog lard under ordinary kitchen conditions does not do this, and these facts offer a starting point for an investigation which would have as its objective a lard substitute with all of the desirable properties of true lard and without any of its undesirable ones.

BUTTER SUBSTITUTES

In the butter substitute factories the opportunities for research are even more promising than in the compound plants, as flavor and physical consistency are there of greater importance. So far margarines, especially those containing only vegetable fats, do not withstand satisfactorily changes in temperature, and it is necessary for the makers to change their formulæ to correspond with the climate in which their products are to be marketed. Butter has a long melting range in comparison with margarines, or, to say the same thing in the cook's phraseology, butter, although soft enough to spread as it comes from the ice chest, does not run until it has been in the hot kitchen for some time, but margarines either become quickly a mass of soupy grease in the summer or when taken from the refrigerator are so brittle that they crumble when one attempts to cut them.

Like butter, the substitutes are mixtures of glycerides, ripened in milk and, after cooling below their melting points, worked to remove the excess of water. The margarine fats in distinction from those of butter must be chilled very quickly to get a homogeneous mixture which will not be granular or streaked in the prints. So far no one has discovered any method by which the fat and milk mixture can be so completely blended that margarine could be churned from the buttermilk as in butter making. It is not essential, of course, that the problem of producing a margarine with a long melting range be solved in this particular way, and it may very well be that some mixture of glycerides will be found, either by combining natural fats and oils or hydrogenating them, which will by the present process yield a slow melting product.

The biochemist has, in the margarine maker's laboratory, a great opportunity for research along the lines of still further improving the flavor of these foods, and especially in finding means, other than by the use of preservatives, for preventing the comparatively rapid spoiling of his products. As the population of this country increases, the difficulty of obtaining a plentiful supply of milk is becoming greater and the demand for a milk substitute more apparent. While perhaps this is not a problem for the oil chemist, still it is so closely related to the margarine industry that it seems worth while mentioning.

PROBLEMS IN SOAP MANUFACTURE

Nothing has been said so far of the specific problems connected with soap making, and space will not permit going into these in any detail, even if the writer were competent to do so. The demand for South American tallow and similar hard fats by the soap manufacturers

during the war, and the fact that many of them are users of large quantities of hydrogenated oils, are indicative of their need for a plentiful supply of raw materials which will make hard soaps. Another thing that causes the soap maker trouble is the keeping properties of his wares; white soaps have a great tendency to turn yellow or dry out and crack, thus becoming less attractive to the purchaser. The increase in the price of sugar makes desirable some substitute for this substance in transparent soaps, and in the bleaching and purifying of garbage grease and refuse fats there are still unsolved problems.

ORGANIZATION OF RESEARCH LABORATORY

A few of the fundamentals of successful research may properly be mentioned in concluding this sketch of the numerous possibilities open to the scientific investigator in the fat and oil industry. The director of an industrial research laboratory should be a man with a broad knowledge of chemistry, but not necessarily a specialist in any one line. He should have a wide acquaintance among the leaders in his profession and know where to turn for specific information on any problem, and also to which college to go for a new man to handle a special line of work. He must be politic but by no means "spineless," so that when his laboratory has devised a process with real merit he can get for it a fair trial by the operating department.

His assistants may well be of two types—first class analysts and men with the research instinct. Many a costly plant experiment has been a failure because of slipshod analytical control work, often due to the all too common notion that it is a "routine job" to do careful chemical analyses and therefore beneath the dignity of a research man. Where the force of assistants is large enough it is well to have in the organization specialists in the different chemical fields of colloids, catalyzers, microchemistry and biochemistry.

In addition to the usual laboratory equipment and such special apparatus as may be needed by the specialists, somewhere between the "lab table" and the plant there should by all means be a "semi-works." This plant, which will necessarily change more or less with each problem, becomes the common meeting ground for the investigator and the operator. It may well be under the direct supervision of the director of the research, but the mechanical department should also be conversant with its equipment and the operating department be cordially invited to make use of its facilities. The large chemical industries have learned that processes worked out on the "gram, centimeter, second" system seldom function according to schedule when translated directly to the factory scale, and have invested thousands of dollars in their semi-works. It is absolutely necessary if a research laboratory is to make good in anything but strictly scientific fields that its discoveries and inventions be carried through the stage where they are perfected in regular plant type—but small-size—equipment. The individual experiments at this semi-works plant should be under the direction of the chemist who developed the laboratory process.

With such a personnel and equipment and the elimination of all petty jealousies between the research laboratory and the production department, a research laboratory will bring as large financial returns in the fat and oil industries as in any of the other fields where chemistry is involved.

More and Better Tools Wanted

A Plea for Reliable Tabulated Physical and Chemical Constants, Especially for Melting Points, Vapor Tensions, Specific Heats, Latent Heats of Fusion and Vaporization, Thermochemical Data, Thermal and Electrical Conductivities and Thermal Emissivity

By J. W. RICHARDS*

THERE are essentially three kinds of research: (1) Investigation of chemically pure materials, the purest obtainable, in order to determine their chemical and physical properties with the highest accuracy, as a basis for scientific study of the influence of impurities.

(2) Investigation of the materials of engineering practically available. These are rarely of the highest purity of singleness of composition, but are such as are available in industry for engineering and technical use. Their study seldom results in laying bare the laws of nature, because of the complexity of the material and the number and amount of the impurities present in the commercial material. Such study is, however, of the highest practical importance in giving the engineer and technologist necessary data to use in his practical work with the actual materials at his disposal.

(3) Use of the data obtained in (1) and (2), principally the latter, to achieve engineering and technical results—i.e., build structures and use materials for all possible purposes, to devise processes and in general to attain engineering and technical ends.

NEED FOR A COMPENDIUM OF RELIABLE PHYSICAL AND CHEMICAL CONSTANTS

The tools of the engineer and technologist are thus very largely the information gathered by researches (1) and (2). The repository of such information is the technical literature, particularly the tables of physical and chemical constants and handbooks of engineering data concerning properties of engineering materials. When we come to consider the present available data which may be classified under (1) and (2), the engineer who understands how to use such data and knows what he wants is continually confronted by great lack of information—in other words, the real engineer needs more and better tools of this kind with which to do his real engineering and technical work.

The writer is convinced, perhaps because of his greater activity in this field, that data of the class (1) are woefully deficient and fragmentary. The best compendium of such information is in the revised Landolt and Börnstein "Physikalische und Chemische Tabellen," revised up to 1912. This has been supplemented by the "Tables Annuelles des Constantes Physiques et Chimiques," of which three volumes have appeared to date and the fourth is in preparation. These, and similar books and tables, are collections of the most reliable data accumulated in the last century or more by industrious scientific men. The data are of all degrees of reliability and of all degrees of incompleteness in any particular line. The quickest way to get an idea of the state of matters is by discussing a few concrete examples.

*Professor of Metallurgy, Lehigh University.

Most of the data of the melting points of thermal compounds are marked by inaccuracy of the instruments used in determinations. Pyrometers of an accuracy of, say, 1 per cent at 1,000 deg. C. are of very modern construction and use. Many of the data prior to 1900 are only approximate, and for temperatures above 1,500 deg. C. are still liable to considerable error. Not only that, but the materials worked with have frequently been impure instead of the highest obtainable purity, and results for this reason also have been erroneous. The melting points of many common compounds have not yet been determined. At the present time many of the data on melting points may be said to be fairly satisfactory, but many also need revision and improvement.

BOILING POINTS

As ordinarily understood by this term, boiling point under normal atmospheric pressure is intended. The proper conception, however, should be that of vapor tension, and the data investigated should be the vapor tensions of substances in the solid and liquid states at all temperatures; the usual boiling point is merely one point in the vapor tension curve. Now, technologists and engineers have occasion to use in many problems vapor tensions of compounds at different temperatures and within wide limits of temperature. An inspection of the best available tables will show very meager data published in comparison with what is wanted. One hundred times as much information as is now in print could be used by industrial chemists and technologists in their everyday work; I am afraid that continued absence of such information for so long engenders the unfortunate feeling among some practical men that such data can be dispensed with or are unattainable. They really are neither the one nor the other; we ought to have them.

SPECIFIC HEATS

When we consider the immense amount of thermal work done, by combustion of fuel or use of electric energy, to heat materials to high and low temperatures, including keeping our buildings warm, etc., it is lamentable how many data concerning the quantity of heat required to bring materials up to any given temperature are so imperfectly known. Most of the specific heats given in tables were determined between ordinary temperatures and 100 deg. C., the boiling point of water, and were, therefore, true only for this range of temperature. A few substances have been investigated to higher temperatures, but these are exceptions and not the rule; many have not been investigated at all. The engineer is confronted with a woeful lack of data on specific heat of substances at moderate and high temperatures, also of specific heats of liquids and

gases. It would be making a liberal statement to say that the tables contain 10 per cent of the accurate information in this line which engineers and technologists could use.

LATENT HEAT OF FUSION

Considering again the immense amount of materials which are melted in the world by use of fuel or electric energy, it is lamentable how little data tables contain concerning the energy required to convert substances from solid to liquid state. Even the latent heat of fusion of iron and steel is in doubt, the guesses at it varying from 33 to 60 units, yet we ought to have accurate figures of the latent heat of fusion of pure iron and pure mixtures of iron in varying quantities, such as steels and cast irons. Similar criticism could be made of other metals and compounds which are melted industrially by the millions of tons, and yet the exact heat necessary to melt them is undetermined.

LATENT HEATS OF VAPORIZATION AT VARYING PRESSURES

Immense quantities of water are evaporated in steam boilers, and the latent heat of vaporization of water is fairly accurately known. Immense quantities of other materials are also evaporated or vaporized in other ways than in boilers, such as being distilled or vaporized from high-temperature furnaces; in many of these cases the actual energy of vaporization involved is practically unknown. The books of tables contain some scattering data; the chances are nine out of ten that when they are consulted for latent heat of vaporization the datum desired is not in them. There is a sad lack of information in this line, not only of the latent heat of vaporization at normal boiling point, but still less concerning the latent heat of vaporization at higher or lower pressures. Yet all of these come into account in technical calculations and are tools which the technologist should have in order to do his work properly.

THERMOCHEMICAL DATA

While we are thankful for the many heats of formation and combination contained in thermochemical tables, yet the requirements of practical use call for very many more, which have not so far been determined. As an example, we know the heats of formation of about forty-two alloys—many, however, unconfirmed and of uncertain reliability. All the alloys classified as brass are represented in these data by only two determinations, neither of which is really within the limits of commercial practice. Heats of formation of the many important steel alloys are practically unknown; the same is true of ordinary ferro-alloys. The heats of combination of metallic oxides forming various industrial slags are only to be approximately guessed at; the actual values for practical use are unknown. The heats of combination of metallic sulphides to form mattes are not known in even a single instance. The heat of formation of the common material FeS , is undetermined. A whole corps of competent thermochemical experimenters could be busied for years on the data which are unknown and badly needed in this field.

THERMAL CONDUCTIVITIES

The proper calculation of heat losses through furnace walls and in all other kinds of apparatus requires correct values for thermal conductivities for different ma-

terials at different temperatures. The literature contains a few such determinations, usually limited to low temperatures. For every one of such existing determinations there are a dozen unknown which are badly needed in thermal engineering.

ELECTRICAL CONDUCTIVITIES

The electrical conductivity has been determined for many metals and a few alloys at ordinary temperatures, and in a few cases up to 1,000 deg. C. There exist only a few determinations on these substances in the liquid state, and such data are of great use in electric-furnace calculations. Similarly for compounds of the metals, refractory materials used for furnace walls, fused salts, etc., existing data are meager and need to be largely increased.

Electric-furnace engineering will never reach a satisfactory basis until there are many more data at hand concerning electrical and thermal conductivities at high temperatures.

THERMAL EMISSIVITY

The property of materials to radiate heat at ordinary and at high temperatures has been determined accurately in only a very few cases. A systematic study in this field is sorely needed. The results would be of great value in calculating radiation losses from all sorts of furnaces, rate of cooling of materials in the air, applying corrections to the radiation pyrometer, and several other chemical and metallurgical problems. There is a splendid field for laboratory research on thermal emissivity.

OTHER CONSTANTS NEEDED BY CHEMICAL AND METALLURGICAL ENGINEERS

This article is already too long, and yet only a fraction of the different fields have been mentioned in which experimental work is pressingly needed, results of which would be put to immediate practical use by chemical and metallurgical engineers. To barely mention a few other lines, without further elaboration, we will cite:

Viscosity of liquids and melted materials of all kinds, such as metals, slags, mattes, glasses, enamels, fused salts, etc.; surface tensions of all sorts of liquids and substances in the melted state; mechanical properties of metals and alloys at all temperatures up to their melting points (tensile and compressive strengths, elastic limit, elongation, contraction of area, fatigue tests, hardness, etc.); mechanical properties of structural materials useful in furnace construction, especially compressive strength at high temperatures; capillary constants for molten substances; dielectric constants of solids and liquids, particularly at high temperatures; critical temperatures and pressures of metals and metallic compounds; coefficients of linear and cubical expansion, from lowest to highest temperatures, in solid and liquid state; solubility of gases in metals and other substances, particularly in melted metals at high temperatures; velocity or rate of ignition of combustibles at different temperatures; temperatures of decomposition of metallic compounds; decomposition pressures of compounds at different temperatures; reaction gas pressures from mixtures of metallic oxides and carbon at different temperatures, etc.

May an awakening soon come!

Metallurgical Laboratory,
Columbia University.

Future Rubber Research

An Appeal for More and Improved Methods of Testing Rubber and Its Products as a Guide to Compounding—Need for Study of Fabric and Design of Products—Continuous Vulcanizing and Temperature Control Essential

By ANDREW H. KING

FOR some time rubber research has been almost entirely in the hands of the chemists. In some respects the progress has been very satisfactory. But since chemical specialists have predominated, the present status of the industry may be described as lopsided. There are now many pressing problems which are essentially of a physical or a mechanical nature. Without detracting in the least from the good work of the rubber chemists, the writer wishes to point out a few of these problems.

Rubber testing is beyond question in most serious need for scientific attention. The methods in vogue today were largely forced on the manufacturers of hose, belting and other mechanical goods by the consumers for their own protection. Naturally these methods were not devised for the scientific exploration of the properties of a compound, but only enough data were desired to show that one article corresponded in value to one previously furnished. It is to the everlasting disgrace of these manufacturers who when compelled to go one mile with the consumers refused to go with them the Biblical twain. However, since it was formerly so easy to jumble a number of materials together and produce sort of a grab-bag product just good enough to get by, this condition can be easily explained if not fully understood. The writer has seen old formulas for hose, tubes, etc., which contained as many as twenty different mineral fillers and half a dozen different rubbers.

Five years ago almost the only criterion for comparing the relative values of compounds was tensile strength. Ultimate elongation was considered, but usually as of secondary importance. Recently an attempt has been made to measure the residuum of plasticity present in all stocks. The Davies-North method of determining permanent set may not be the last word—undoubtedly is not—but it is at least a step in the right direction. This is the quality the old line compounder measured with his fingers because his testing machine would not show it to him.

Wiegand at St. Louis last April emphasized very strongly the importance of stress-strain curves. It has been recognized for years that Hook's law does not apply to rubber. The ratio of stress to strain is itself a variable. The area under the stress-strain curve may be measured with a planimeter and from it the energy expended in stretching the test piece may be calculated.

Wiegand obtains his stress-strain curves with a Scott machine and two observers. It is a rather expensive method, but there is no testing machine which will serve. For that matter, the makers of testing machines have been more energetic in selling their product than in developing it to fit the needs of the industry. For example:

(a) All American machines are built to apply load

to the piece at a rate of 20 in. per minute. Now it happens that a constant rate of elongation is not nearly as desirable as uniform increment of load. Machines should be built to give so many pounds per sq.in. increment per minute.

(b) The charting devices on all American machines plot increased load against jaw separation, which because of slippage is variable and has no bearing on the properties of the stock. The design of a good charting device depends largely on getting the proper grips, which unfortunately do not exist today.

In Europe the Schopper machine, which requires ring test pieces, is in use. American factories have declined to use this machine because of the difficulties of obtaining proper test pieces and the fact that due to unequal inner and outer circumferences the stress is not applied evenly and consequently the piece fails by tearing. However, it seems to me that we have been straining at a gnat and swallowing a camel.

In the matter of hysteresis, which is of maximum importance, there is no machine available except the Schwartz. This is, however, too light for high tensile strength compounds and has not the proper grips for straight test pieces. It is also unsuitable because of the method of applying the load. It seems remarkable that no one has yet published a description of a good hysteresis machine. Hysteresis is probably a measure of internal friction, a property which is now giving the solid tire men some worry.

Hardness is another quality as yet not satisfactorily measured. Some of the difficulty is in the matter of definition, but one machine which purports to measure it by deformation has so much friction in its bearings, etc., as to render all results worthless.

For resistance to abrasion we are also without satisfactory methods of measurement. Only makeshift apparatus designed after the grindstone are available.

Resistance to repeated stretching and to tearing are also important. The makers of testing machines are not yet aware of it.

Then there is the question of an accelerated age test. There are no methods which are quite satisfactory. For that matter, how much do we know about the aging of rubber and rubber articles? For my part I am willing to admit that in many cases I have no idea what causes it or how to stop it, let alone how to measure it.

It is my firm conviction that if we can catalog and evaluate the properties of rubber the designing of compounds for special purposes will be rendered much easier and surer than it is today.

In order to understand these phenomena better optical or other methods which will show us exactly how the particles of filler are contained by the rubber and something as to the structure of the rubber itself are quite necessary. Schipple's volume increase with

elongation may be one way. Metallographic methods ought to be of great value.

One could go on indefinitely pointing out work that should be done, but since space is limited this must be taken up later.

COMPOUNDING

Compounding was once the mystic art of the rubber industry. It is becoming, and rightly so, much less secretive. Some day American rubber men will understand that our national reputation hinges on all American products being absolutely satisfactory. The ceramic industry, which was formerly in the same boat with rubber, realizes this fact and co-operation is the watchword now.

However, we cannot get very far with a study of compounding until the physicist gives us better and more accurate methods of testing. Also compounding experiments should not be carried on solely from the physical standpoint. The information regarding the change in coefficient of vulcanization must be obtained simultaneously. It is remarkable how few rubber companies keep an accurate check on free and combined sulphur in their compounds. The steel companies are forced to maintain large routine laboratories for sulphur, manganese, fixed and graphitic carbon, etc. Sulphur plays the same part in rubber as carbon does in steel, yet we are indifferent to its variation. This is in most cases due not to the compounder but to a stingy policy of the directors, who may be excellent men but are ignorant of the fundamental reaction of their industry.

North's paper on compounding ingredients which was read at St. Louis last April was a good beginning. Other rubber laboratories should contribute their bit and soon we would begin to have some valuable fundamental information which is lacking at present.

In accelerators I believe we have enough for the present. Let us thoroughly investigate the few which we now know to be of value before going into this subject much deeper.

FABRIC

Cotton fabrics are employed throughout the rubber industry. Yet how much do we know about them? For example, fabric must be held in place by rivets of rubber which are forced between the threads. It is almost impossible to make rubber stick to cotton threads. Why?

The internal friction of the fabric in a tire generates a large amount of heat. How can this be cut down or eliminated? Cord tires heat up less, but even they are not entirely satisfactory in this respect.

There are any number of problems directly bearing on the rubber industry which are not being worked on, at least they have not been described.

DESIGN

In matters of design we are not exactly in a sound position. In tires nothing essentially new has come out for a long time.

A question which has never been satisfactorily answered is that of the stresses in these articles. The writer is of the opinion that in general the tires, etc., just happened to be put together and no special study of the forces encountered was made. In other words, many tires, etc., are poorly designed and fail not because of the materials but because of the design.

The supply of gutta percha for ocean cable is diminishing rapidly. A substance which will replace it will be very acceptable.

The fiber sole is now in general use. They must be cheapened and a method for rendering them slightly porous must be worked out. Leather is decreasing in supply and not only soles of rubber but tops of rubber and fabric are needed.

CONTINUOUS PROCESSES

There is still too much intermittent hand work in the rubber factories. Machines for hose- and tire-building are in use, but the steps are far from being continuous. There are many other instances. For example, hose, tires, etc., are vulcanized in large heaters with steam. When the proper time has expired the steam is blown off and the heater cooled so it can be opened. Just consider the quantity of heat absolutely wasted. With coal at \$8 or more a ton this cannot go on. Continuous processes of vulcanizing must be worked out.

TEMPERATURE CONTROL

Temperature control, because of the extensive use of organic accelerators, is very important. Unfortunately too many companies depend on poor thermometers, which are rarely if ever checked up. Presses are particularly bad because they do not as a rule give the same temperature between all decks. The temperatures of mills and calenders are still judged by hand. Surely instruments can be developed for their direct measurement.

The rate of heat flow through fabricated articles such as a dredging sleeve, a pneumatic truck tire or a solid tire is of maximum importance in designing the stocks which are to be used. Unless this is carefully studied the surface is likely to be overvulcanized while the center will be porous or undercured. Very few accurate scientific data are available on this subject.

CONCLUSION

The writer has not attempted to go into detail on any one phase of the problems mentioned above. But surely there are so many big problems to be attacked that laboratories not employing physicists should engage a good one at once.

It should be unnecessary to point out that the British rubber factories are getting together and have organized a strictly British Rubber Research Laboratory under the management of the well-informed and able Dr. Twiss. The war has taught them the advantages of co-operation. But has this lesson been learned by American firms? Their men have helped in the work of the Rubber Section of the American Chemical Society, but the "powers that be" in certain of the older firms are "agin it." The English have been slow in many respects in rubber, but if they really pull together we may expect some strenuous competition and should be organized accordingly.

Surely the jealousy and antipathy which defeated the plan for an extensive co-operative rubber library in Akron a few years ago must be effectively killed. Is it not possible that a study of the physics of rubber and of rubber products, a study which is so broad that no one firm can hope to handle it alone, may not be the basis for that co-operation which we all desire but from which so many are held back for fear the other fellow will not come through with what they want to know after they have answered his question?

The Future of Chemical and Engineering Research in the Pulp and Paper Industry

Prospectus on Pulp and Paper Research—Byproduct Possibilities and Reduction of Wastes—Less Liquor Dilution by More Efficient Washing—Fuel and Power Costs Reduced by Use of Vacuum Drying and Better Designed Beaters

By JOHN STEVENS, 3d

IN THE past ten years chemical progress in the manufacture of paper, the processes of which are so often thought of as being of a purely mechanical nature, has been exceeded in no other industry and stands as a striking example of the value of chemical control and research when applied in an intelligent manner. In fact it was no more than six years ago that one of our largest paper corporations, operating seven mills, possessed as its chemical staff one graduate chemist assisted by a boy to conduct such routine tests as were at that time considered sufficient to maintain the highest degree of efficiency! Today this same manufacturer has a staff of fifty chemists and engineers in addition to a small army of laboratory assistants whose duties consist of testing not only everything that enters into a product but the condition of the product in its various stages of manufacture as well. There can be only one result of such a drastic change of policy—an unprecedented standardization of heretofore rule-of-thumb methods coupled with the development of new processes, revealed through chemical research, which have made great strides particularly toward an efficient recovery of valuable byproducts.

CHEMICAL CONTROL VS. RESEARCH

The work of the chemist in the paper industry has up to the present time, therefore, been concerned largely with the control of existing processes together with research in the byproduct field. It is now quite apparent, however, that there are an infinite number of problems which remain unsolved and upon which the chemist must bend his efforts in the future. The fact that they exist reflects in no way upon the ability of the paper chemist, as it should be realized that his time has been occupied largely by the control of present processes; with a few exceptions, he has not been able to carry on extensive research. Many of the larger manufacturers have maintained research laboratories in addition to those devoted primarily to process control, but such development has been comparatively recent and has not had the opportunity, due largely to the short lapse of time, to demonstrate fully the wisdom of such a step.

On the other hand, the results obtained at the Brown Company under the guidance of such men as Moore and Richter should certainly serve as conclusive evidence that research in the pulp and paper industry is of infinite value. The utilization of waste sulphite liquor and the recovery of various byproducts from the gases and liquors of the alkaline pulp processes have occupied a prominent position for some time and considerable research has been devoted to these problems.

In view of present circumstances in the paper indus-

try, however, it appears that the chief concern of the research chemist and engineer in the future should be directed to the study of fibrous raw materials and how best to prepare them, in an economic way, to take the place of our rapidly vanishing timber resources, together with a study of possible improvements in existing processes.

BYPRODUCT POSSIBILITIES AND WASTES

The wastes incident to the conversion of wood into paper pulp are not confined wholly to the loss of non-fibrous constituents, which in the past have either gone into the sewer or been utilized for their fuel value, but a large part of these wastes are the result of careless cooking conditions and inefficient methods of handling the product. It is not at all uncommon to find a mill realizing a 38 per cent yield of pulp when a 43 per cent yield would surely result from slight variations in the cooking schedule; but what is even more distressing is to see fully ten tons of valuable pulp lost in the back waters for every one hundred tons of paper made. Such a state of affairs emphasizes the fact that the enormous demand for paper is not the only reason for the depletion of our forest reserves but that wasteful treatment of our paper-making materials within the mills themselves is partly responsible. Furthermore, a 10 per cent saving in pulp would be far more profitable to the manufacturer than the recovery of byproducts has proved to be up to the present time. Has not the time therefore arrived for those in charge of scientific development in the paper mills to regard the treatment of the fibrous raw material, both as to source and as to process of manufacture, as of equal importance with byproduct recovery?

REDUCTION OF POWER CONSUMPTION

At this writing a great deal of promising research is being carried on in this and other fields and many of the most fundamental processes in paper manufacture are due for a rude jolt in the very near future. Much of this late development, such as the drying of paper continuously in a vacuum and improved methods of beating the pulp, is of largely mechanical nature, although none the less important, and will contribute as much as any chemical achievements to the advancement of the industry.

Furthermore, the processes of beating and drying are largely responsible for the enormous consumption of power in the paper mill and anything that can be done to save this valuable commodity is well worth the expenditure of considerable research. Take the matter of beating, for example; why should it be necessary to circulate pulp, say, 1,500 lb. to a beater load, for five

hours or more to effect the proper hydration for manufacture into papers requiring this quality, and in an apparatus which requires from 50 to 60 hp. throughout the operation? Surely there must be some simpler way, and an excellent opportunity is offered to the chemist, with his knowledge of the hydration of cellulose, to co-operate with the mechanical engineer in the design of more efficient equipment to effect this end.

Very similar to present beating practice is the manner in which pulp is ordinarily washed, particularly in the manufacture of high-grade papers. Here the half-stuff circulates around in washing engines of the same

EXPERIMENTAL 30-IN. COMBINATION CYLINDER AND FOURDRINIER PAPER MACHINE

general shape and design as the Hollander beater, except for the fact that the beater roll and bed-plate are supplanted by a paddlewheel to cause the motion of the stock. Fresh water is added continuously and the dirty water leaves at the same rate through the trunnions of several perforated washing drums that dip into the pulp.

MORE EFFICIENT WASHING

To those familiar with the methods of washing in other industries this practice must appear queer indeed. This is not at all surprising, as after all such an operation is virtually a dilution process and does not represent in any way the correct principle of displacement used in other industries. What the paper makers need in regard to washing is a method by which the dirty washings are successively removed from the pulp previous to their displacement by clean water. This method is, of course, used in pulp mills for the removal of bleach residues, but its application throughout the trade is still limited and is open for future development.

VACUUM DRYING

The drying of paper is still another of the more or less mechanical processes in the paper mill which presents excellent possibilities for investigation. There are three main considerations in regard to the problem of drying—namely, the amount of steam used, the temperature of the steam, and the temperature difference between the steam and the paper. It is common knowledge that 50 per cent of the steam supplied to present drying systems is lost. This fact alone should war-

rant an extensive investigation of methods to improve this condition. It is also known that high temperatures are particularly injurious to the strength and quality of papers. This requires that in any improved process of drying the temperature of the steam must not be raised above that already found suitable.

We now come to the question of temperature difference, which governs largely the speed at which paper dries. The drying of paper in the atmosphere with steam at 5.3 lb. pressure within the driers will give a temperature difference of only sixteen degrees—that is, the difference between the temperature of the steam, 228 deg. F., and the temperature at which the water in the paper is boiled off, or 212 deg. F. Let us see what will happen if this same paper were dried in a vacuum of 28 in. of mercury using steam in the driers at the same pressure. The boiling point of water under a 28-in. vacuum is 100 deg. F., so the temperature difference is now 128 instead of 16. This means that the paper will be dried $128 \div 16$, or 8 times as quickly under the vacuum as under atmospheric pressure and, furthermore, at a lower temperature. Therefore, one-eighth the number of driers in the ordinary atmospheric system would do the same amount of work and effect a considerable saving in steam at the same time, if placed under a 28-in. vacuum. Such a vacuum drying system is being developed and is an indication that the future may look to many revolutionary changes in paper drying.

SULPHATE PROCESS AND NEW PULP MATERIALS

It is in regard to the utilization of fibrous materials, however, that chemical research can best be applied in the immediate future in the pulp and paper industry, and it is with this end in view that the few sugges-

BEATER EQUIPMENT USED FOR SEMI-COMMERCIAL EXPERIMENTS ON NEW FIBROUS RAW MATERIALS

tions that appear here are written. It is when this point is reached that it becomes evident that the future of paper pulp manufacture centers largely around the so-called sulphate process. It so happens that practically all of the new materials now being introduced to the paper trade, such as waste cotton fiber, sugar cane, bamboo, etc., are best adapted to this process and open up at once a fertile field for research. Curiously enough, it has been found that bamboo, so treated, will yield a remarkably easy-bleaching pulp which is des-

tined to act as an excellent substitute for wood pulps used today.

There are, however, certain to be many problems incident to the introduction of these new materials into commercial practice and no small portion of them will be up to the pulp mill chemist to solve. Many of these fibrous materials do not contain enough ligneous matter to furnish adequate fuel for the burning of the liquors in the recovery process; others contain so much silica that the gelatinous silica compounds formed in contact with the alkaline liquors are bound to interfere with the settling and filtration of the lime sludge in the causticizing process.

EXPERIMENTAL ROTARY DIGESTER USED FOR THE SODA AND SULPHATE PULP PROCESS

These, and many other problems relative to the utilization of new raw materials, have heretofore received too little attention, which has resulted in the publication of many misleading statements. If all of the governing factors, both technical and economic, were carefully considered, it is doubtful whether more than 5 per cent of the materials proposed would be found suitable for paper manufacture. Too many investigators consider only the quality of the pulp and it never seems to occur to them that digester yield, liquor recovery and location of materials bear an equally important part. Nine times out of ten it has been found by experience that, although a material may produce a most satisfactory pulp, the yield per cu.ft. of digester space is only from one-third to one-half that of ordinary pulpwoods. This means that a four-digester soda mill would have to be turned into probably a ten-digester mill to obtain the same production from some of these new materials. It requires only simple calculation to reveal the fact that the effect on the annual investment return is quite discouraging.

In connection with the sulphate process itself, without the consideration of its application to new fibrous raw materials, there are many opportunities presented for improvement. A reliable, reasonably durable system of indirect cooking to prevent dilution of liquors is still to be found; there is room for engineering development on tumbling digester trunnion attachments and steam inlet arrangements to prevent leakage; an efficient method of washing the pulp to supplant diffuser systems and further prevent liquor dilution is desired;

in the recovery end there is needed a good automatic feed for charging smelters; also chemical research looking toward a more valuable utilization of the various substances contained in the lignin dissolved in black liquors than using them for fuel and evaporating purposes; the disposal of lime sludge is an important problem which should be solved in the immediate future, as many of the mills are now contemplating this step.

PULP FROM SOUTHERN PINE

The application of the sulphate process to many of our common pulpwoods such as the Southern pines should offer possibilities of improvement. It is doubtful, however, if it will ever be practicable to manufacture bleached pulps from extremely pitchy woods, such as the long leaf pine, by this process.

The content of resins in this pine is very high, when considering it as a pulpwood, but if looked at from the standpoint of the rosin and turpentine industry it is too low for economical operation. For example, the stumpwood used by the extraction plants often contains 24 per cent rosin, while the pulpwood seldom averages over 5 per cent. There have been attempts in late years to combine the extraction and pulping processes, but up to the present time this has not been successful on a commercial scale. The fact that the wood is prepared by a hog for extraction and that the extracting process removes most of the resins is ample explanation of the failure of previous attempts. Hogged wood cannot be used in the ordinary pulp digesters and black liquors in the sulphate process will not burn off if the resins which constitute a large part of the fuel value are first removed from the wood. It therefore appears that this problem has been attacked from the wrong angle and that there is room for valuable research.

In the first place, the proper sized chip must be determined which will "strike a happy medium" between the ideal hogged wood in the extraction process and the larger chips in the pulping process. It is certain, however, that either one or both of these processes will have to sacrifice something in order to obtain satisfactory operating conditions with a combination of the two. After the rosin and turpentine have been removed from the chips, the next logical step seems to be the application of a pulping process that does not require liquor recovery. We are therefore limited to the sulphite process and with certain variations in cooking conditions from the ordinary practice there is little doubt that a good quality bleachable pulp can be produced. Engineers and designers should also come forward and evolve an apparatus which will allow the extraction and pulping operations to be carried out in the same piece of equipment.

This and other problems as briefly reviewed in this paper emphasize the fact that the surface of chemical research in the paper industry has merely been scratched and that myriads of opportunities exist for future development. No doubt the foregoing review of some of the possibilities afforded may be characterized in the same way—there is so much yet to be done and so little mentioned. The conception of the idea is a very small part of the success of a project, however, so that what is now needed is the diligent solution of the many problems and not mere suggestions.

Applied Colloid Chemistry

A Summarized Outline of the Present-Day Role of Colloid Chemistry as Applied to the Solution of Widely Diversified Theoretical and Practical Problems in Inorganic and Organic Industrial Chemistry

BY WILDER D. BANCROFT

I HAVE stated elsewhere that a knowledge of colloid chemistry is essential to anybody who really wishes to understand about: cement, bricks, pottery, porcelain, glass, enamels; oils, greases, soaps, candles; glue, starch, and adhesives; paints, varnishes, lacquers; rubber, celluloid, and other plastics; leather, paper, textiles; casts, pencils, and crayons; inks; roads, foundry cores; coke, asphalt; graphites, patines, zinc, phosphorus, sodium, and aluminum; contact sulphuric acid, hardened oils, etc.; beer, ale, and wine; cream, butter, cheese, and casein products; cooking, washing, dyeing, printing; ore flotation, water purification, sewage disposal; smoke prevention; photography; wireless telegraphy; illuminants; comets; pharmacy; physiology.

WHAT COLLOID CHEMISTRY IS

Since the connection of some of these with colloid chemistry may not be obvious to everybody I am going to run over some of the points which involve colloids. Since a phase is defined as colloidal when it is sufficiently finely divided, colloid chemistry may be called the chemistry of bubbles, drops, grains, filaments and films, because in each of these cases at least one dimension of the phase is very small. This is not a strictly scientific statement, because a bubble cannot exist without a film around it, and both filaments and films may be considered as composed of coalesced grains or drops. Jellies also present some difficulties because they are not obviously fibrous, and if we classify them as thick films we cannot say that one dimension is extremely small. These difficulties are inherent in any rather epigrammatic classification and are not serious.

COLLOIDS IN THE CERAMICS INDUSTRY

When clay is heated the grains sinter together and form bricks which are less porous the higher they are heated. Sintered refractories involve the same principle but different raw materials. When selected clays are used with addition of fluxing material we get the different forms of pottery. Porcelain is a modified silica glass made translucent by crystals of sillimanite, $\text{Al}_2\text{O}_3\text{SiO}_2$, and it has been suggested that some of the furnace losses in making porcelain might be cut down by using powdered sillimanite in the mix. If the heated mass fuses more or less completely and does not become entirely crystalline on cooling we get a glaze or a glass as the case may be. In the colored glasses and glazes the coloring matter is often colloidal, ruby glass being the stock example. A white enamel is a glaze made opaque by suspended particles of stannic oxide, calcium phosphate, zirconia, or something of that sort. Haber states that 3,000,000 kg. of stannic oxide was saved per year by adding the stannic oxide to the enamel in such a way as to cause less of it to be dissolved.

Cement owes its value to the power of the fine grains to gelatinize with water and set. Other things being equal, the resulting concrete is stronger the finer the grinding of the clinker. When the Lackawanna R.R. built its famous viaduct the specifications called for more finely ground clinker than most plants could furnish. In making plaster casts the time of setting and, to some extent, the grain size are modified by the addition of colloidal substances. Some of the good qualities of alloy steels are due in part to the other elements bringing about a more finely grained structure. The use of addition agents in electroplating and electrolytic refining involves the decrease in crystal size due to adsorption of the addition agent. The gelatine in photographic films gives us colloidal silver bromide and the ripening process changes the amount of adsorbed gelatine. The concomitant coarsening of the grains is purely incidental. One of the factors determining the capacity of the lead storage cell is the porosity of the grids. Experiments by Prof. Briggs of Cornell University make it probable that the effect of lithium hydroxide in the Edison cell is to produce suitable grain size and degree of porosity. The color and opacity of pigments vary with the size and structure of the grains. The possibility of adding a white filler like ground barytes to a red pigment without making the tint paler depends on the fact that fine powders tend to coat coarser ones. When writing with a pencil or crayon the surface to be written on must abrade the writing instrument and must hold the resulting powder in place.

The formation of coke involves the obtaining of a granular structure giving strength and porosity. The modern gas mask owes its efficiency chiefly to the adsorbing properties of porous charcoal. The catalytic action of pulverulent solids is the important factor in connection with contact sulphuric acid, Deacon chlorine, Haber ammonia, Ostwald nitric acid, Chance-Claus sulphur, Sabatier hydrogenation, dehydration and dehydration, surface combustion, Welsbach mantles and many other things. The use of fullers earth depends on its adsorbing properties.

SUSPENDED COLLOIDAL PARTICLES

The Cottrell process for removing fumes involves the electrical transference of suspended grains and drops. With such illuminants as candles, oil, gas and acetylene the light is due to incandescent carbonaceous particles. The tails of comets contain colloidal particles and their luminosity is apparently a large-scale occurrence of the Tyndall beam.

Enzymes and bacilli are in colloidal solution and consequently all fermentation processes involve colloid chemistry. The whole subject of toxins and antitoxins will undoubtedly have to be worked out as a problem

in adsorption. Most writing inks consist of suspended particles, as in the case of the carbon inks and the old-fashioned iron-tannin inks, or of solutions which oxidize on the paper, forming grains there. We know that soap forms colloidal solutions in water, and it is probable that the fats are in colloidal solution in many oils and other organic liquids. So-called solutions of rubber and of cellulose are always colloidal, and so are the cellulose nitrates when apparently dissolved in amyl acetate, acetone, or ether and alcohol.

Colloidal fuel is said to be less dangerous than straight fuel oil because it is denser than water and accidental fires can therefore be put out by water. Water purification is due in part to the carrying down of bacteria and suspended particles by gelatinous alumina, etc. The red coloring matter of grape juice and of the wine that is made from it is colloidal and can be filtered out by means of an ultra-filter. Cocoa is obviously a colloidal solution and both appearance and flavor vary markedly with the method of preparation. In coffee and tea the suspended particles cannot be seen by the naked eye, but they are there.

The so-called tannin solutions used in making leather are colloidal. Casein is in colloidal solution in milk and its precipitation is the first step in the manufacture of cheese. The asphalt from Trinidad contains finely divided siliceous matter suspended in it. When making sodium or aluminum electrolytically the temperature of the bath must be held as low as possible or there will be undue formation of the so-called metallic fog, with enormous decrease in current efficiency.

EMULSIONS

Milk is an emulsion of butter fat in water. Other well-known emulsions are mayonnaise, cod-liver oil and lanolin, this last being an emulsion of water in wool-fat. By adding water to a mineral oil containing a lime soap we get an emulsion of water in oil which is so stiff that it constitutes a grease. The stabilizing action of water on ready-mixed paints is due to the formation of an emulsion of water in oil with rosin as emulsifying agent. The rubber latex is an emulsion about which we have read, though few of us have seen it. The fact that rubber is in the form of liquid drops is accounted for by assuming that the rubber is depolymerized; but this explanation could scarcely be applied to milk, though the butter fat occurs as liquid drops.

In pharmacy the making of emulsions is an empirical art and it is only recently that the scientific side of the subject has been developed. Although Cottrell has done brilliant work on the converse problem of destroying emulsions, we must admit that as yet there has been no systematic study of this subject in spite of its importance in the oil industry.

The properties of emulsions are of tremendous importance in physiology, because they enable us to account for the antagonistic action of sodium and calcium salts and for a number of the properties of protoplasm. Emulsions are used in preparing foundry cores for baking and in the kerosene spray for trees, merely to mention two instances. The solid alcohol of commerce is a jelly and not a stiff emulsion.

SELECTIVE WETTING

Selective wetting is the underlying principle of the Elmore bulk oil flotation process, and it is no longer necessary to dry white lead before grinding it with oil,

because linseed oil displaces water readily and completely from the pigment. The separation of finely ground coal from ash by means of oil is a special application of the Elmore process. The shower-proofing of fabrics is done by coating the fibers with a substance which is not wetted readily by water and the treated fabric then lets air through readily but stops rain, at least up to a certain point. •

THE IMPORTANCE OF BUBBLES

Bubbles play an important part in making certain soaps float, in bread, and in giving the color to white flowers, and white hair. The formation of foam on beer is due to the colloidal albumoses in the beer, which increase the viscosity of the films around the bubbles and consequently make the bubbles more permanent. In the case of champagne there is less colloidal material in suspension, the films around the bubbles are less viscous, and the foam is much less stable. For lecture experiments the law makes it necessary to substitute near-beer and ginger ale, but the principle remains the same.

The fighting of fire by the use of Foamite is an interesting application of bubbles. The method fails when applied to burning aluminum powder because the aluminum powder is carried up in the film and because aluminum will burn in carbon dioxide, reducing it to carbon monoxide. Ore flotation depends on the selective wetting of the ore by the oil and on the formation of bubbles. In the Minerals Separation process the films are very viscous and it is scarcely an exaggeration to speak of armor-plated bubbles. In the Callow process there are fewer particles in the surface films, which are consequently less viscous and the bubbles are therefore more fragile. It was recently stated that 60,000,000 tons of ore was treated by flotation process in 1918. Some experiments have been made on removing colloidal matter from sewage by a process similar to the Elmore bulk oil process; but this was not a success. It is quite possible that better results might be obtained by a modification of the bubble process.

FIBROUS COLLOIDS

Paper, textiles and leather are all fibrous colloids. The tanning of leather consists essentially in making one colloid insoluble by the addition of another, tannin or chromium oxide, in the vegetable and mineral tanning. Artificial silk is an important industry depending on the properties of filaments, and certainly no one can question the technical importance of the incandescent lamp. It is still something of a question whether soaps, jellies, celluloid, rubber, etc., have a fibrous structure and are to be considered as filaments, or whether they have a honeycomb structure and are to be considered as emulsions; but nobody will dispute their being colloids.

COLLOIDS IN FOODSTUFFS

Cooking of meat involves changes in a distinctly colloidal material; poaching or scrambling eggs depends on the coagulation of colloids. The amount of fat adsorbed by a doughnut is quite surprising. The staleness of bread is not necessarily due, as most people suppose, to an actual drying, but apparently involves a displacement of the water equilibrium between the starch and the gluten. Mashed potatoes are certainly colloidal, and the cooking of cereals is partly a problem in the swelling of colloids. In fondant we have grains

of sugar made plastic by surface films of a solution of partly inverted sugar. This suggests the possibility of making fondant without cooking by starting from confectioners' sugar and a glucose solution.

ADSORPTION PHENOMENA IN DYEING

The dyeing and printing of fabrics involve adsorption upon fibers. In calico printing the coloring matter is mixed with British gum or some other thickener to prevent its running. When a coloring matter will not dye cloth directly the dyeing can be done by mordanting the cloth, a mordant being a substance which adsorbs the dye and is adsorbed by the cloth. The metallic mordants are used chiefly for the acid dyes, while tannin is one of the most satisfactory mordants for the basic dyes. Owing to the ease with which tannin is peptized by water it is usual to fix the tannin on the cloth by means of tartar emetic.

FUNCTION OF SOAP IN WASHING

Washing is the removal of adsorbed material, usually by peptization. Soap is adsorbed readily by the dirt and removes the latter from the fabric or the flesh. Dry cleaning is peptization by organic liquids instead of by water. Ink may be removed from old newspapers by washing with soap, by treatment with sodium silicate, or by froth flotation. Rit is a series of dyes, made up apparently with some soap. It will dye fabrics, but does not stain the hands.

ADHESIVE PROPERTIES DUE TO ADSORBED SURFACE FILMS

The importance of glue and other adhesives is due to their forming films which are adsorbed strongly by the surfaces which are to be held together. It is because of the difference in adsorption that we have to use different adhesives with different substances. If the film remains liquid it will both hold the particles and make the mass plastic, as in the case of wet sand, of fondant, and of oiled roads. With more liquid we change from plastic flow to viscous flow. The oil requirement for pigments is apparently the amount necessary to give a certain degree of plastic flow. When water forces fine sand into the state of loose piling we have the conditions for quicksand.

OTHER EXAMPLES OF SURFACE FILMS

A drying oil forms a surface film which may be used to hold the pigment grains firmly on the painted surface. Varnishes and lacquers are surface films intended to give increased permanency and beauty. The whole question of the manufacture of varnishes is one that should be turned over to the colloid chemist. It does not seem possible that the present purely empirical methods can be the best. Patines are films of salts adsorbed on metallic surfaces. The adsorbed oxide films on the surfaces of aluminum and nickel decrease the corrosion of these metals and make it possible for us to use them commercially. Passive iron owes its properties to the presence of an adsorbed film of a higher oxide. When condensing phosphorus or zinc vapors the important thing is to prevent the formation of films around the drops. That the structure of graphite is an important factor is shown by the greater apparent density of the natural graphite, which makes it better for use in crucibles. The electric-furnace graphite made at high temperatures is not so good for lubricating purposes as the more flaky and unctuous graphite obtained at somewhat lower temperatures.

The detectors and coherers used in wireless telegraphy appear to function, at least in part, because of adsorbed air films. Electrolytic reduction is due to monatomic hydrogen produced at the cathode and a high concentration of this substance is the cause of hydrogen overvoltage.

Cornell University.

Filtration of Colloids

Dr. W. R. Ormandy, who contributed a paper on "The Osmose Process for the Filtration of Colloids," at the July 13 meeting of the Society of Chemical Industry at Newcastle, said that the special method of treatment under consideration depended on the utilization of certain properties of finely divided particles in suspension. The new process for the application of physiochemical laws is in many respects so new that it is necessary to deal shortly with the underlying principles before the methods of their application and the limitations of the process can be properly understood.

Colloids can be divided into at least two groups, the reversible and the irreversible colloids. To the reversible group belong such substances as glue, gelatine which can be dissolved in water, dried and again dissolved in water without any great alteration in properties. To the irreversible group belong such substances as albumin, which after treatment with boiling water become absolutely insoluble. For the most part, however, the nature of the colloid is largely dependent upon the size of the particles. Sufficiently fine particles when suspended in water exhibit what is known as the Brownian movement, which is the more energetic the smaller the particle. This Brownian movement is now regarded as the visible symbol of molecular bombardment, as has been largely proved by the researches of Prof. Perrin. Generally speaking, particles of matter exceeding 0.0001 mm. in diameter will eventually settle from solution. This is about the limit of microscopic visibility. The fact that particles below the limiting size do not settle means that the molecular and electrical forces outweigh the action of gravitation. So far back as 1869 Jevons noticed that the intensity of the Brownian movement of clay particles was increased by the addition of traces of certain types of bodies and inhibited by the addition of other types of bodies. In 1895 Bliss noticed that a clay suspension exhibited increased Brownian movement with the addition of traces of alkali, but that the addition of further quantities again reduced the movement. It has long been known that the addition of certain types of chemicals tended to cause coagulation of colloids suspended in water; thus the addition of calcium hydrate and aluminum sulphate to bring about the settlement of sewage sludge is ancient history.

Dr. Ormandy took a suspension of ball china, to which had been added the necessary amount of electrolyte, and poured it into a copper cylinder having a carbon pole suspended in the center. On passing a current of about 60 volts through the liquid so that the central carbon pole was the anode, the clay was not only deposited very rapidly on the anode, but, although the clay was deposited under water, the clay on the anode was found to be remarkably dry. This result was due to the peculiar action by which water was repelled from the anode through a porous diaphragm, the action being known as electro-endosmosis. If, instead of using a stationary anode, a horizontal rotating anode was used, this process could be made continuous.—*Chemical Age* (London), July 17, 1920.

The Leather Industry

Many of the Problems Awaiting Solution in Such Phases of Leather Manufacture as Unhairing, Deliming, Bating, Tanning, Stuffing and Dyeing Involve Fundamental Scientific Principles Which Can Best Be Studied Through Co-operation Between University and Tannery Chemists

BY JOHN ARTHUR WILSON*

IN THE hands of men thoroughly trained in modern chemistry, capable of original research, and provided with the facilities of a tannery, chemistry will probably eventually revolutionize the industry. But in the hands of less able men it is a source of danger that many a tanner has learned to his sorrow, with the result that even today a number of tanners either employ no chemist at all or else limit the work of those they do employ as chemists to mere analytical routine, and this in the face of the fact that the processes used in making leather are essentially chemical. The leather chemist has made considerable progress, but it has been small compared to what might have been expected from the progress of the pure science. Yet it is not difficult to see why greater results have not been achieved in the field of leather chemistry; the great majority of men who enter the tannery as chemists have an education no greater than that ordinarily required for the degree of bachelor of science, and this alone is entirely insufficient to cope with the real problems of the industry.

INDUSTRY DEVELOPED THROUGH EMPIRICAL EVOLUTION

The manufacture of leather is a most complex chemical industry and many of the processes in use today are the results of centuries of rule-of-thumb juggling. Along with the development of processes, accompanied as they often were by very costly failures, the practical tanner acquired an appreciation of the extreme danger of deviating very far from established practice. If he thought a process could be improved, he would first make only the slightest change and then wait weeks, perhaps months, to note any effect upon the finished leather. If no difference, or possibly a slight one for the better, could be detected, he would then institute a bigger change. Often it would be found that a small improvement in one process necessitated corresponding changes in several other processes. The young chemist usually fails to appreciate the need for this extreme caution and he is often ignorant of his ignorance of the fundamental chemical principles involved in making leather. When such a man is given free rein in the tannery, the results are much more likely to be fatal than profitable.

STUDY OF FUNDAMENTAL PRINCIPLES ESSENTIAL

The first applications of chemistry should be devoted to investigations of the molecular mechanism of present processes, the fundamental principles of which are not yet definitely known. Any increase in knowledge in this direction would permit the establishment of more satisfactory systems of control over the processes. In such investigations it is likely also that new principles would be discovered and these might form the basis

for new and better processes. Because much of the necessary experimental work would require very refined apparatus and great skill in accurate measurements, it would seem that the best results would come from close co-operation between the industry and the university.

With little extra work and no sacrifice of any of the objects in view, the chemist of the university could make much of his research in pure chemistry of direct value to the industry if only he were aware of the industry's needs. Often a very elaborate and painstaking research would prove of the greatest value to leather chemistry if a few additional data had been obtained, which would have been easy enough with the apparatus set up and the work in full swing, but which would present formidable difficulties to the tannery chemist without suitable equipment. It would undoubtedly prove very profitable for the industry to finance research on a large scale at the university, and all results of such work should be published freely to be of greatest good. While the work would be primarily concerned with the chemistry of leather manufacture, it will be seen from the problems now to be outlined that the field is so broad that the gain to pure science would probably be fully as great as that to the industry.

SOAKING THE HIDES

Hides are received at the tannery in any of four different conditions: fresh, salted and wet, salted and dried, and dried without salting. The first of the chief operations is "soaking," which consists in putting the hides into vats of water and changing the water frequently until the hides are clean and have reached equilibrium with the water; usually several days are required. Dried hides absorb water very slowly, but they must remain in the soak vats until they have acquired their normal amount of water or the leather later on will not have the proper suppleness. The process of imbibition is sometimes hastened by adding alkalis to the soak water.

UNHAIRING

The next step is to free the hides from hair and epidermis and this is commonly done by putting the hides into saturated lime water containing an excess of lime and some sodium sulphide. Since these liquors are used over and over again after restrengthening, they generally contain decomposition products of the protein constituents of the hide, such as polypeptides, salts of aminoacids, amines, and ammonia, and all of these seem to play a part in this process, which is known as "liming."

After the hides have been in the liquor for several days, the malpighian layer of the epidermis is destroyed and the corneous layer and the hair may simply be

*Chief Chemist, A. F. Gallun & Sons Co., Milwaukee, Wis.

rubbed off, and this is done on a suitable machine. Sometimes arsenic sulphide is used instead of sodium sulphide to "sharpen" the limes, and similar use has also been made of lye and of ammonia. In earlier times lime was used alone, but the action of pure lime liquors is extremely slow and satisfactory results were obtained only with old liquors that had become heavily charged with decomposition products of the hides and probably also with bacteria. Another method, once widely used, was to put the hides into a warm chamber

GRAIN SURFACES OF GOAT SKIN (A) AND CALF SKIN (B) ($\times 8$)

where the epidermis was destroyed by putrefaction. Where the cost of labor has been large compared to the value of the hair, some tanners have employed strong solutions of sodium sulphide alone to destroy the hair, the hides being practically free from hair and epidermis when hauled from the vats. An unhairing action can also be produced by dilute solutions of ammonia and by pancreatic enzymes. All of the processes mentioned leave something to be desired and the whole subject of unhairing is in need of a much more thorough investigation than has yet been made.

DELIMING

Two more general processes complete the preparation of the hides for tanning: the removal of lime or other alkalis from the hides and a curious process known as "bating." The bulk of the lime is removed simply by washing, and the remainder, which has either carbonated or is combined chemically with the hide protein, is removed by treatment with dilute acids or is sometimes allowed to remain in the hides until removed by the acids present in the tanning liquors.

BATING OR PUERING

Bating, or puering, originally consisted in putting the hides into vats containing a warm infusion of the dung of birds or dogs and leaving them there until the "plumping" action of the lime liquors had been counteracted and the hides had become soft and raggy. Just how the early tanners hit upon this process is a matter for speculation, but the fact remains that the method appeared to be necessary to get certain desirable results in the leather. Investigations, notably that of J. T. Wood of Nottingham, seemed to indicate that pancreatin is the active constituent of the dung, and now mixtures of pancreatic enzymes and ammonium chloride largely replace the obnoxious dungs. But the question as to why we bate at all is still a moot one. Many tanners, especially those making heavy leathers, do not bate; others claim that good leather cannot be made without bating. If the object of bating were

simply to counteract the alkaline swelling of the hides coming from the limes, this could easily be accomplished by reducing the hides to a nearly neutral condition, and some tanners claim that this does produce the desirable effects of bating. Recently, however, evidence has been brought forth to show that, in bating, the elastin fibers of the papillary layer are digested by the enzymes present.

The foregoing represent what are known as the "beam house" operations and their prime object is to free the hides from everything excepting the collagen fibers and hyaline layer of the true skin, which is then ready to be tanned.

TANNING

There are numerous methods of tanning, of which only the two most important will be mentioned: these are vegetable tanning and chrome tanning. While the origin of vegetable tanning is lost in antiquity, chrome tanning is a product of the last few decades and is often referred to as the one big contribution of chemistry to the leather industry. These two processes and the materials involved in them have been the subject of the great majority of investigations made in the industry, and yet it cannot be said that we have made more than a start in the direction of solving the chemistry of tanning.

CHEMISTRY OF VEGETABLE TANNING PROCESS STILL OBSCURE

Vegetable tanning, as its name implies, consists in the conversion of hide into leather by means of material procured from plant life. The barks of trees, such as the hemlock and oak, the wood of quebracho, chest-

CHROME TANNED COWHIDE ($\times 15$)

nut, etc., and the leaves and fruits of many plants contain matter which is soluble in water and capable of tanning hides. The hides upon coming from the beam-house are first suspended in vats containing very dilute solutions of these tanning materials, each day or two they are moved into stronger liquors, and are finally hauled out when the color of the tan liquor has completely penetrated the hides as shown by examining a cutting in the thickest part of a hide.

Simple though this process may seem, its chemistry is exceedingly complex. Many theories of the mechanism of the process have been propounded and there is still no general agreement on any theory. The process is one in which the tanner finds he dare not deviate much from his daily practice. If the liquors become too strong or too acid, there is danger of the grain surface becoming rough or wrinkled to such an extent that it cannot later be made smooth and the value of the leather is lessened considerably. If the liquors are not sufficiently acid, the tanning action is retarded and the liquors and leather become darker in color through oxidation.

Different kinds of tanning materials often produce very different kinds of leather, but it is still a matter of some doubt as to whether such differences are due to differences in the active tanning principles which they contain or to differences in the content of foreign matter, such as acids and sugars or other fermentable substances. Some evidence has been brought forth recently to show that astringent tanning materials differ from milder ones chiefly in possessing less of non-tanning matters of acid character. Many difficulties that sometimes confront the tanner in the later processes are traceable to slight changes in the condition of the tanyards.

VEGETABLE TANNING PROBLEMS SUITED FOR UNIVERSITY RESEARCH

Much of the research required on the subject of vegetable tanning is especially suited for university laboratories. Among the more important problems in this connection might be mentioned the chemistry of the tannins, the swelling of the collagen fibers by dilute acid solutions and the opposing action of the tannins, the diffusion of the constituents of a tan liquor into the substance of the hide fibers, the effect of change of acidity upon the tanning action, and the nature of the tanning action itself. It will be found convenient in university studies of these problems to use a standard hide powder which has been placed on the market by the Standard Manufacturing Co. of Ridgway, Pa., especially for use in tannin analysis. This powder is made up chiefly of purified collagen fibers containing about 12 per cent water, 0.3 per cent ash and about 0.8 per cent of fat.

CHROME TANNING

Chrome tanning consists in treating the hides first with a solution of sulphuric acid and common salt, a process known as pickling, and then with a solution of basic chromic sulphate corresponding roughly to the formula $\text{Cr}(\text{OH})\text{SO}_4$. Since chrome liquors are usually made by reducing sodium dichromate, they also contain a considerable amount of sodium sulphate. Sometimes the hides are taken from the pickle bath and put into a separate tanning bath and sometimes the chrome preparation is added directly to the pickle liquor containing the hides. After the hides have been drummed or churned in the chrome liquor for a day or more, the green color of the chrome will have penetrated them completely and they are then tested to determine whether or not the tanning is complete. This is done by keeping strips of the leather in boiling water for five minutes or longer; if they are fully tanned, the boiling water will apparently be without effect upon them, but any unchanged collagen present will be con-

verted into glue, causing a considerable distortion of the strips. When the hides are not fully tanned at this stage, it is generally necessary to reduce the acidity by a cautious addition of alkali.

COMPLEXITY OF CHROME TANNING PROCESS

It would seem that tanning with inorganic salts and acids should be less complex than vegetable tanning, but the process is nevertheless almost bewildering in its complexity. Work now in progress at Columbia University has already shown that chrome liquors are much more complicated systems than we previously had reason to believe, although anyone who has done much experimenting with chrome tanning must have experienced the annoyance of not being able to duplicate certain results because of the variation of some unknown and therefore uncontrollable factors.

A. W. Thomas and his collaborators at Columbia have shown by hydrogen electrode measurements that the acidity of a chrome liquor changes with the time, especially just after some change has been made in the liquor, such as dilution or the addition of acids or alkalis. The acidity is markedly increased by adding neutral chlorides, such as common salt, and is decreased by neutral sulphates. They showed also that neutral salts have a similar action upon solutions of

COWHIDE FROM SOAK VATS (X 17)

hydrochloric acid or sulphuric acid. It is quite evident, then, that before we can hope to control every factor in chrome tanning we must learn more about pure solutions of acids and salts. It is in further studies of this kind that the pure chemist can be of very great service to the industry and it is desired that he should appreciate the possibilities for applying his discoveries. An increase in the acidity of a chrome liquor retards the tanning. The addition of sodium chloride increases the acidity and, as would be expected, retards the tanning. On the other hand, the addition of sodium sulphate decreases the acidity, but it also retards the tanning. The explanation of these facts surely lies within the province of the pure chemist.

The writer has done much work on theories of tanning and believes that vegetable tanning consists of the combination of collagen and tannin, yielding collagen tannate or vegetable leather, and that similarly, in chrome tanning, we have the formation of a chromium collagenate, collagen being amphoteric. On

this basis the combining weight of collagen appears to be 750, or some multiple or submultiple of 750. This view has been contested, but its truth or fallacy should interest the pure chemist.

FATLIQUORING AND STUFFING

After tanning, by either the chrome or vegetable process, the hides are fatliquored or stuffed. Fatliquoring, which is applied to light leathers, consists in drumming the leather with a hot emulsion of suitable oils. If the condition of the leather is right and the

VEGETABLE TANNED CALFSKIN (X 40)

proper quantities of materials have been used, the leather will remove practically all of the oil and leave nearly pure water behind. Stuffing consists in treating the hides with greases, such as a mixture of cod oil and tallow, which are often added hot to the dry leather. The object in applying oils to leather is to prevent brittleness, to increase strength, and to impart other properties desirable for certain types of leather, such as waterproofness, etc. There is much room for experiment in the making of suitable emulsions.

DYEING

Another important process is the dyeing of leather. A pack of skins which has been kept together through every process may emerge from the color drum with some skins light in color and others dark. Any one skin will be uniform in color, but one skin may be much darker than another. The writer has found that slight differences in the amounts of acid carried by chrome-tanned skins cause them to take different amounts of dye from the same bath, but difference in acidity of different skins scarcely furnishes the full explanation.

UNIVERSITY CHEMISTS SHOULD DEVELOP THEORIES

The research work which the industry needs is of two very distinct kinds, the one pertaining to the discovery of facts and of reasons for certain processes and the other the correlation of those facts and application of them to actual leather manufacture. The former requires an extraordinarily broad knowledge of general chemistry and great skill in dealing with specific

problems in many different fields of chemistry. For example, in studying the mechanism of bating, the investigator should have a knowledge of both bacteriological and enzyme actions, he should be familiar with the action of electrolytes upon proteins and with the work of H. R. Procter of Leeds and others upon the swelling of proteins in certain solutions by absorption of water, and he should be skilled in preparing and staining cross-sections of the hide for microscopic examination.

At the end of his investigation he might be able to say with certainty that bating has two and only two important functions, the counteraction of the swelling caused by the limes and the removal of elastin fibers from the papillary layer. Such a statement properly substantiated would do much to elevate a now uncertain process to a scientific basis. In the study of chrome tanning the investigator must have some very refined apparatus, particularly a good hydrogen electrode, and he must have a very thorough knowledge of physical chemistry. He might be able to settle definitely the molecular mechanism of tanning and show exactly what essential rôles are played by the salts and acids present. For the purpose of solving problems of this kind the university is vastly better prepared than the tannery.

CHEMISTS FAMILIAR WITH TANNERY PRACTICE SHOULD APPLY THEORIES

But when it comes to correlating such facts as the university chemist might discover and applying them to actual leather manufacture, a tannery is necessary as well as a chemist thoroughly familiar with its practical workings, and this of course the university could scarcely be expected to furnish. This would of necessity be the work of the tannery chemist, and such tanneries as do not employ chemists might fail to profit by the work done at the university. For example, suppose the university chemist proved the value of bating and recommended the use of a certain type of bating liquor that was slightly alkaline. A tanner who now delimes his stock with dilute acids, but does not bate, reads of the great discovery and attempts to profit by it. He follows the instructions carefully, but the resulting leather is much inferior to what he has been making. He concludes that bating is detrimental and remains satisfied with his deliming process. He has gained nothing from the research simply because he did not have in his plant a chemist with sufficient training and knowledge of the tannery to see that good results could not be expected until the vegetable tannery was altered to conform to the changed condition of the stock coming from the beamhouse. Before instituting the bating process, the stock arrived in the yard in a slightly acid condition. After bating, the stock was slightly alkaline. To meet this changed condition, either the tan liquors should have been more strongly acid or the stock should have been put through the usual deliming process after the bating. Thus a given discovery might be hailed as a success by certain tanners whose processes chanced to be specially suited to receive it, while other tanners would consider it a failure.

The industry needs the help of the university chemists and it also needs highly trained chemists holding positions of responsibility in its tanneries; its development will be greatest when these two groups of chemists learn to do teamwork.

MACHINE PROCESS OF MAKING WINDOW GLASS

Putting the Glass Industry on a Scientific Basis

The Role of Modern Science in the Ancient Art of Glassmaking—Developments Due to Engineering—Refractories and Raw Materials—Accomplishments of the Chemist

BY E. WARD TILLOTSON*

GLASS and glassmaking ever have had a peculiar appeal to the imagination of all peoples. Glass, possessing many of the attributes of precious jewels and in addition possessing the susceptibility of constructive formation, is particularly adapted not only for articles of use but also for pieces of art in which the form, decoration and coloring reflect the artistic sense of the glassworker. Glassmaking as an art practiced in secret for centuries has been surrounded with the glamour of mystery and the masters of the art have enjoyed the patronage of royalty and the perquisites of the nobility.

DEVELOPMENTS DUE TO ENGINEERING

During the last two centuries, however, conditions incident to the advancement of civilization have swept away many of the mysterious formulas. The establishment of the glass industry in this country marked the beginning of scientific advancement in the technology of glassmaking: the economic situation prevailing in a civilization such as ours makes impossible the maintenance of a great industry in a state of technical secrecy. It is not to be inferred that the industry is free from ignorance and prejudice or that glass manufacturers do not jealously guard certain secret processes, but it is only just to say that in no other country are

glass factories more open to inspection for casual visitors and for business competitors. The glass manufacturer in general realizes that an exchange of ideas is of greater value to both parties than any doubtfully guarded secret could be to either one.

The first advances in glassmaking in the United States and the most widely known American contributions to the industry consist in the applications of mechanical appliances and the making automatic of many glass-making processes. For example, the pressing of glass, an American invention of one hundred years ago, has passed successively through hand-fed hand-operated presses, hand-fed power-operated presses, and now certain pressed glass articles are manufactured by automatic machinery which carries out the operations of "gathering" the molten glass, pressing the article, transferring it to and conveying it through the "leer."

IMPROVEMENT IN BOTTLE MAKING

A similar development has taken place in the manufacture of bottles, bulbs for incandescent lights and other articles involving pressing or blowing or even a combination of the two operations. In the window-glass industry the process, though of more recent date, has been equally brilliant and of far-reaching importance. Machines not entirely automatic, to be sure, draw huge cylinders from a pool of molten glass, and not only is the product of a far better quality than that

*Assistant Director of the Mellon Institute of Industrial Research.

produced by the old "hand-blowing" process, but the great economic saving marks the introduction of machine-drawn window glass as a revolutionary achievement. Of the very recent developments in machine-made window glass mention should be made of a process in which "endless" flat sheets of glass are drawn and passed continuously through the leers. It is considered that this machine is an assured success. Obviously it possesses certain advantages over the cylinder machines, not only by reason of its continuous operation but also because the expensive operation of "flattening" is eliminated.

LITTLE PROGRESS IN PLATE-GLASS INDUSTRY.

The plate-glass industry has not experienced any spectacular developments of the nature of the inventions just mentioned; the operations as carried out at present are fundamentally the same as those of Thevart in 1688, with, of course, modern furnaces and leers and mechanical appliances for handling the glass in the several operations. This particular industry has been slow to develop in this country, but in recent years the requirements for windshields and other plate-glass fittings for automobiles have greatly stimulated the production of plate glass.

Mention should be made of "wire glass," which is manufactured by processes analagous to those employed in plate-glass manufacture. It is an American invention and represents perhaps the greatest advance in the application of plate glass for special purposes.

In the other glass industries American manufacturers have had the advantage of large resources of raw materials of a high degree of purity and of cheap clean fuel (natural gas); and while these factors have con-

tributed to maintain the quality of American glassware on a par with that of other countries, revolutionary developments in certain lines have not been made.

than is commonly supposed or acknowledged. Little has been written of the chemist's accomplishments, except, perhaps, in connection with the development of optical glass during the past few years.¹ Chemical contributions have been isolated, sporadic and, unfortunately, dimmed in the shadow of a general policy of secrecy which has resulted partly from tradition and partly from fear of legal complications. Such conditions do not make for real scientific progress in this or any other industry, but it is believed that the present is a period of transition and it is certain that great opportunities exist for the chemist and that his work in the future in conjunction with that of the physicist and engineer will transform the whole aspect of glass technology. The problems which are to be solved include the basic principles of all the operations involved and of the materials employed. The problems in connection with refractories, furnaces, fuel and raw materials are shared in common with all branches of the glass industry.

THE ROLE OF THE REFRACTORIES

The pots in which glass is melted and the walls of the tank melting furnace are made from certain refractory fireclays. The curious situation is therefore presented of melting one type of silicate in a container composed of another type of silicate which is slowly but surely dissolved by the molten material. Unfortunately, none of the common metals possesses properties satisfying the requirements for these containers, and such substances as are known to be insoluble in molten glass have not yet been bonded successfully with an equally refractory and insoluble cement. The proposal has been made that the tank be constructed as a water-jacketed iron box. Walls of chilled glass would thereby be formed of the same composition as that of the glass to be melted. This would appear to be an almost ideal solution of the refractory problem, but in trial certain faults have been disclosed. Between the walls of cool and comparatively rigid glass and the channel of flowing molten "metal" there exists a zone in which the conditions are favorable for devitrification. Crystallization of some of the components of the glass occurs and these crystals are gradually carried to the working end of the tank and appear as defects in the finished product. When the chemist has succeeded in preventing devitrification in glasses of the type melted in tanks, this water-cooled tank will perhaps have a large field of usefulness.

THE POT AN IMPORTANT FACTOR

The use of green or partly burned pots and blocks is not to be considered as entirely satisfactory. Even if the pot is burned carefully in the pot arch, it is subjected to a higher temperature in the furnace. As a result, the back wall and crown are more thoroughly vitrified and subjected to considerable shrinkage, while the bottom and front walls are protected from the heat and remain more porous and do not shrink. This condition results in the introduction of large strains in

FILLING END OF A LIBBEY OWENS FURNACE

tributed to maintain the quality of American glassware on a par with that of other countries, revolutionary developments in certain lines have not been made.

ROLE OF THE CHEMIST AND PHYSICIST

It is, therefore, evident that American contributions to the advance of the glass industries have been largely from the engineering standpoint. It is not to be supposed, however, that the chemist and the physicist have entirely neglected these great industries. In fact, the part of these scientists has been of greater importance

¹For a concise review of the contributions of the chemist to the optical glass industry see A. A. Houghton, *J. Ind. Eng. Chem.*, vol. 7, p. 290 (1915). In speaking of developments in this country Mr. Houghton says: "America's contributions to the development of the glass industry, chiefly in methods of working and handling the molten glass, are epoch-making in character; along more strictly chemical lines creditable work has been done, as instanced by the Tiffany or Aurene glass, the selenium red, and others. Aside from optical glass, on which a beginning is being made, the glasses produced in this country probably are fully equal in quality and variety to those produced abroad; and in some respects America is forging ahead." For a recent report on the status of the optical glass industry, see R. J. Montgomery's "Twenty-three Types of Optical Glass," *J. Am. Ceram. Soc.*, vol. 3, pp. 404-10 (1920).

the pot walls and contributes to a lessened life by reason of breakage and for other causes.

Certainly the several operations involved in the manufacture of the pot or the block are of an equal importance with the kind of clay employed and a thorough understanding of these operations would be of inestimable value to the glass industry.

The historic glass furnace is illustrated by the open pot and covered pot furnaces in common use. These furnaces are admittedly inefficient and cannot be considered as satisfactory from any standpoint. With covered pots, especially, the heat necessary for melting the glass is generated within the furnace and must traverse the walls of the pot before it can perform its work. Even with efficient regeneration—and few of the installations can be so classified—the waste of heat is sufficient to justify the most serious consideration. Because of this the use of pots except for melting certain kinds of glass may be expected to decline.

The introduction of the tank furnace has made possible the quantity production of glass which has justified and prompted the development of automatic machines. This type of furnace represents something of an advance over the pot furnace from the standpoint of heat efficiency, but still leaves much to be desired. The tank was used first for window and bottle glass, but has been adapted to melting "lime flint" or "crystal" glass, and the indications are promising that even "lead" glass may be produced in it commercially; it will undoubtedly be employed for any glass whenever the volume of production justifies.

The melting of glass by electrical energy has been the subject of much experimentation, and it is understood that elaborate trials of this principle now are being conducted. Molten glass is a fair conductor of electricity; and if the electric current can be passed through the molten glass and the heat be thereby developed within the charge, it appears that the optimum conditions of efficiency will be realized.

RAW MATERIALS

The great developments of the glass industry during the past forty years have been associated with the supplies of natural gas. This fuel, which was ideal for the use of the glass manufacturer, is failing rapidly and even now is to be considered as a pleasant memory. The question of fuels is largely an economic one. Glass factories always have been located near the supplies of cheap fuel, but with the improvements in the manufacture of producer gas this consideration will perhaps be of less importance in the future. The necessity in melting and annealing glass of an ashless fuel and one as free as possible from sulphur and other impurities probably excludes all solid fuels except as they are gasified in the producer; and while in a measure successful, the use of fuel oil does not appear to become general by reason of its growing cost and of its lessened availability. Improvements in the design of furnaces and of regenerating systems which will admit of a more efficient application of the fuel and of a better control of combustion will be of material aid in conserving our fuel resources and in making for economy in the industry.

²For example, most of the colored glasses and other special glasses are used in too small a quantity to justify the use of a tank in their production. The more intensely colored glasses, in addition, are so impermeable to radiant heat that they may be melted only in pots; and pots are thought necessary for chemical reasons in the making of ruby glasses.

The American glass manufacturer is favored with large supplies of raw materials possessing a high degree of purity. The sand, lime and soda which are available are not surpassed in any country. Good as the sand is, however, it contains small amounts of extraneous minerals, containing iron, titanium and other color-producing oxides, the economic and complete removal of which would materially lessen the "color" problem in the manufacture of the finer grades of glass.

The importance of the chemical control laboratory should be pointed out in this connection. Automatic machines demand "metal" of constant viscosity, heat conductivity, "hardness" and other physical properties. It is therefore important that the composition of the glass be maintained as constant as possible from day to day. When it is considered that not only does the composition of the raw materials vary in different shipments but that some of the materials—for example, the "lime" (CaO with more or less MgO)—change in composition during storage by reason of absorbing moisture or carbon dioxide, it is evident that the scientific production of even the more ordinary kinds of glass necessitates constant and adequate chemical control.

The substitution of limestone for burned lime, the addition of feldspar or other aluminiferous minerals to the batch and the use of other glassmaking materials are problems not only of economic importance but are also essential in scientifically adapting the properties of the glass to its intended use. A new source of potash would be of benefit to certain branches of the glass industry.

PROBLEMS IN SPECIAL BRANCHES OF THE INDUSTRY

Each branch of the glass industry has its own individual problems. In the present state of the window-glass industry, for example, there are many problems in connection with eliminating the relatively minor

TAKING OFF GLASS AT END OF LIBBEY OWENS SHEET DRAWING MACHINE

difficulties consequent on the creation of a new and great manufacturing procedure.

Similarly in the machine-production of bottles and "packers" the majority of the problems of immediate

³Since no glass has a definite melting point, the word "hardness" has been used to denote the temperature at which it possesses a prescribed viscosity.

importance are related to the perfecting of the several processes which are competing for supremacy. The situation is one of mobility and of rapid progress, and it appears that the man of scientific training may have an important part in the developments of the future which will determine whether each of the automatic and semi-automatic machines will have a particular use of its own or whether one of them will prove to be so superior as to be of universal application.

The plate-glass industry is waiting for fundamental developments. At present the glass is melted in open pots and from these is poured on to the casting table, on which it is rolled. A means for conveying glass melted in a tank furnace to the casting table without the introduction of bubbles or other defects would almost revolutionize the industry. The mechanical appliances for handling the huge plates of glass have been highly developed and important innovations in the annealing process have been made, but the procedure employed in grinding and polishing, in spite of recent improvements, is impressive in its awkwardness complexity and lack of economy. A fundamental solution of this technologic problem may perhaps be the deciding factor in the future of the polished plate-glass industry.

In all these industries, as well as those represented by a smaller volume of production, there is need for a wealth of scientific data of a chemical and physico-chemical nature. The chemical reactions taking place during melting require scientific investigation; the principles of annealing glass have not been wholly worked out, and the building of leers to apply these principles is necessary for scientific annealing. A better understanding of the physical properties of glass at all temperatures and of the relation of the chemical composition to the physical properties is of real importance, not only in its fabrication in automatic machines but also in the development of new glasses or of glass for specific applications.

The adsorption of gases on glass surfaces and the behavior of glass to the solvent action of water and solutions is also of importance. A cheap glass of lesser solubility would find many uses and a glass of great mechanical strength would be desirable for containers which are to be used repeatedly.

To mention all the problems of the glass industry would be to discuss every detail in the manufacture and uses of glass. It should be mentioned, however, that a pink, red or ruby glass has not yet been produced in which color is constant throughout the operations and heat treatments which are involved. A highly colored red glass of permanent tint used in conjunction with the well-known blue glass, "powder blue," would form an ideal "decolorizer" and would be appreciated

by the glassmaker. The use of colored glasses for signaling, for color screens in photochemical work and for goggles and spectacles to protect the eyes indicates the importance in the manufacture of these glasses of a scientific understanding of their properties, production and uses. The successful application of artificial illumination is associated closely with the glass used, and the scientific production of translucent and other glasses of the required properties offers a fruitful field of investigation for the scientist.

ACCOMPLISHMENTS OF THE CHEMIST

Examples of what the chemist already has accomplished in the glass industries will occur to any one who is familiar with this field of manufacture. The German scientist has received his share of glory in the development of the optical glass industry, but the American inventors have been given little publicity. The American contributions of "lime flint" glass, and recently of new laboratory glassware, of glass of extremely low coefficient of expansion, of glasses of peculiar properties for particular uses, and, during the war, the rapid establishment of a whole optical glass industry, under the direct supervision of scientists from the Geophysical Laboratory and the U. S. Bureau of Standards, are noteworthy accomplishments and are indicative of greater achievements when the glass industry has been put on a scientific basis.

The responsibility for fulfillment of this condition rests equally upon the scientist and upon the industrialist. It is fair to conclude that the glass manufacturer is not yet convinced that the scientist has an understanding of his problems or the ability to solve

OWEN 15-ARM AUTOMATIC MACHINES

This machine is capable of producing 350 gross of pint bottles per 24 hours, equivalent to the work of fifty hand operators.

them equal with that of his practical glassmaker. It is probably true that the chemist often has failed to

⁴Invented in 1865 by William Leighton, Sr., of Wheeling, W. Va. Leighton used sodium bicarbonate in place of soda ash, which at that time contained quantities of impurities.

SOME NOTABLE DEVELOPMENTS IN THE GLASS INDUSTRY

Innovation	Date	By Whom Introduced	Place	Comments
First glass factory in America.....	1608		Jamestown, Va.	For the manufacture of beads and bottles.
Pressed glass.....	1827	A carpenter, name unknown	Sandwich, Mass.	The Boston & Sandwich Glass Co., Deming Jarves, mgr.
First plate-glass factory in America.....	1857		Williamsburg, N. Y.	Failed by reason of competition from France and Belgium.
Flint-glass.....	1864	William Leighton, Sr.	Wheeling, W. Va.	This invention nearly extinguished the old flint industry.
First regenerative pot furnace.....	1865	James B. Lyon	Pittsburgh, Pa.	Built at the O'Hara Glass Works, for use with producer gas
First continuous tank in America.....	1879	Poughkeepsie Glass Works	Poughkeepsie, N. Y.	For the manufacture of bottles.
First use of natural gas in melting glass.....	1882	Bradford Window Glass Co.	Bradford, Pa.	In 1884, gas was used for melting flint glass in the Riverside Glass Works, Wellsburg, W. Va.
Prepressed blank.....	1882	Philip Arbogast	Pittsburgh, Pa.	An important step in the development of the automatic bottle machines.
Continuous leer for window glass.....	1882	Cleon Tondeur	Dunhamville, N. Y.	Fox & Sons Window Glass Co. (the "rod" leer).
Continuous tank for window glass.....	1884	United Glass Works	Streator, Ill.	
Wire glass.....	1892	Frank Schuman	Tacony, Pa.	
Favrille glass.....	1892	The Tiffany Furnaces	Corona, L. I.	
Selenium ruby glass.....	1894	Nicholas Kopp	Pittsburgh, Pa.	
Flint glass melted in tank.....	1898	Charles H. Runyon	Rochester, Pa.	Keystone Glass Co.
Continuous leer for plate glass.....	1898	Marsh Plate Glass Works	Walton, Pa.	
Fire polishing cut glass blanks.....	1899	Michael J. Owens	Toledo, Ohio	
Automatic bottle machine.....	1899	Michael J. Owens	Toledo, Ohio	
Machine drawn window glass.....	1900	John J. Lubbers	Pittsburgh, Pa.	The American Window Glass Machine
Machine drawn sheet glass.....	1903	Irving W. Colburn	Franklin, Pa.	The Lobbey Owens Sheet Glass Machine.
Flowing device.....	1903	Homer Brooke	Jersey City, N. J.	Used in connection with automatic machines.
Continuous leer for flint glass.....	1908	Maryland Glass Corporation	Baltimore, Md.	The intermittent pan leer had been in use for fifty years.
Low expansion glasses.....	1915	E. C. Sullivan & W. C. Taylor	Corning, N. Y.	Pyrex glass
Hartford-Fairmont feeder.....	1915	Karl E. Peiler	Fairmont, W. Va.	For use with automatic machines.
Automatic tube machine.....	1916	Edward Danner	Toledo, Ohio	
Automatic bulb machine.....	1917	August Kadow	Toledo, Ohio	The Westlake machine producing bulbs for incandescent lights

produce results in the glass factory; it is also probably true that the glass manufacturer has not understood what he might expect of the chemist and has not had a sufficient comprehension of science to utilize the services of the chemist to the best advantage. It is evident, therefore, that a fundamental consideration in putting this industry on a scientific basis is a more adequate training of chemists and chemical engineers in glass technology. The number of our universities which offer courses in the chemistry of glass is distressingly small and there remains to be established in any school an adequate course in glass technology in which the knowledge of the practical glassmaker is correlated with the known principles of chemistry and physics. The opportunities offered in this field and the knowledge that men of scientific training will be required in the glass industries constitute the primary arguments for the establishment of such courses of training, and the assurance of co-operation on the part of the industrialist will be of material aid and is indeed necessary in the consummation of this desirable purpose.

Such a course in glass technology should not only develop men for research and control work but should also offer to the practical man an opportunity to gain such a knowledge of scientific principles as will be of benefit to him in working in sympathetic accord with the scientific men in his factory. A mutual understanding on the part of men associated together is an essential of success.

In this principle is undoubtedly to be found the reason for instances of failure of the chemist in the glass industries. The chemist has not been trained to understand the point of view of the men making glass and the practical man has not understood the point of view of the chemist. In many industries in which the professionally trained man forms an essential part it has been found advantageous to give him in the factory an additional special training in the particular business of that factory. The recognition by the glass manufacturer of the fundamentals of this situation will quickly react to his advantage. The work of the chemist, particularly if he is engaged in research, lies within a field which properly comes under the direct jurisdiction of the chief executive of the organization. It is notable that in those concerns which have made the best use of the chemist he has come into a position of high executive responsibility. One instance,

of many, may be cited in which the chief of the chemical laboratories is one of the five principal officers who report directly to the president of the company. This method of organization does not presuppose that the president is a man of scientific training, but it does assume that he has a sympathetic understanding of the relation of his business to the scientific principles involved.

It is not to be expected that even a large number of chemists working independently and in isolation in the laboratories of a large number of glass factories will, in the highest sense, put the glass industry on a scientific basis. Science supposes organization and experience has demonstrated that united efforts are more productive than equally intense but dispersed expenditure of energy. The success which has accompanied the research laboratories established by associations of manufacturers in a united purpose for the common good may well be considered by the several glass industries. The establishment in England of the Glass Research Association under the auspices of the Department of Scientific and Industrial Research is to be taken as indicating the beginning of concerted effort to apply scientific principles to the manufacture of glass, an attitude of co-operation which is commended to the attention of the glass industries in this country. Other industries have learned that properly conducted scientific laboratories yield substantial returns.

The glass manufacturer may again read the words of an old-time but progressive glassmaker. "In an age of progress, whoever clings to the methods of the past will soon be neglected and forgotten."

Safety Glass Factory at Mount Vernon, N. Y.

The Triplex Safety Corporation of New York is operating a factory at Mount Vernon, N. Y., for the manufacture of its products. In this plant ordinary window glass is carefully graded as to size and thickness and thoroughly cleaned and dried. Two plates are then put together with sheets of celluloid between and cemented with a cement having the same optical properties as the glass.

Glass treated in this manner can be shattered by hard blows, but will not splinter. A sample made up of three such thicknesses of glass was not penetrated by a bullet discharged from a 0.45 caliber automatic.

Recent Developments in the Hardwood Distillation Industry and Suggestions for the Future

Work on the Increase and Variation of Yields of the Pyroligneous Products: Acetate of Lime, Methanol and Charcoal—Cord Sticks Cut Into 5-In. Blocks—Control of Retorting Temperatures—Central Research Organization

By L. F. HAWLEY*

IN A brief article¹ published in 1913 the writer called attention to many technical operations in the process of wood distillation in which efficiency studies would be of great value. Since that time there has been considerable progress both in research work and in the commercial application of the fundamental facts discovered.

Work on the variation in yields of products from different species of wood has continued,² and new plants have been built in sections of the country where the industry had not previously existed. More attention is also being paid to the use of mill wastes such as slabwood by distillation plants near which such wastes are available.

On the effect of moisture content of the wood on the yields obtained during distillation some experimental figures have been published by Palmer and Cloukey.³ So far as we know these results have not been applied to any great extent in practice, but another development in connection with the moisture content of wood has been made by commercial plants. Formerly the drying of dis-

tillation wood was entirely by natural methods consisting of one year to eighteen months air drying. At two large plants artificial drying of the wood in three days has taken the place of this long period of air drying with resulting reduction in cost of piling wood in the yard and in interest charges on wood in storage.

CORD STICKS CUT INTO 5-IN. BLOCKS

Artificial drying has also led to another change in methods, on account of the fact that rapid drying is better obtained with small blocks of wood than with the ordinary 4-ft. stick. For the drying process, therefore, the wood has been cut into blocks about 5 in. long, and from this point onward the wood does not need to be handled, but is carried through the process entirely on the cars in which it is distilled. Although there is some extra cost in preparing these blocks and a small proportion of the wood is lost in the form of sawdust, these are more than counteracted by the lower cost of handling and the other economies mentioned above.

CONTROL OF RETORTING TEMPERATURES

A few years ago R. C. Palmer, then connected with the Forest Products Laboratory, called attention to the possibility of influencing the yields of valuable products by more careful control of the temperature of distillation. It had previously been known that by a very slow distillation the yields of a cord of wood could be increased, but Palmer showed a method by which the

EDITOR'S NOTE.—In endeavoring to eliminate the use of the terms wood alcohol and methyl alcohol, the Committee on Occupational Diseases of the American Chemical Society has suggested that these be replaced by methanol or methyl hydroxide. Since methanol has been adopted by some of the leading producers, it will be used in these pages in place of wood or methyl alcohol.

*In Charge, Section of Derived Products, U. S. Forest Products Laboratory, Madison, Wis.

³J. Ind. Eng. Chem., vol. 10, p. 262 (1918).

yields could be increased without increasing the total length of time required for distilling a charge of wood. This was accomplished by very rapid heating at the beginning of the run with constant watching of the temperature and distillate so that the heat might be cut down just in time to prevent the distillation from "running away." This method of temperature control has been commonly adopted by the larger wood distillation plants and has been of great benefit to the industry.

PRODUCTS FROM WOOD TAR

There has recently been some development in the preparation of marketable products from hardwood tar, but only a few plants are now making a complete utilization of this product by the preparation from it of marketable products. The developments along this line have been so favorable, however, that it is very likely that the utilization of hardwood tar will increase rapidly in the near future. The usual method of recovery of acetic acid and light oils from tar by distilling with steam in the wooden tar still has been studied with the result that the most efficient conditions for the operation have been determined.

The products carried off in the non-condensable gas are still being lost at the same rate that they were several years ago. A few crude attempts have been made to recover a part of these products, but the subject has not been properly studied and the installations have not been very efficient or profitable.

THE ACETATE, METHANOL AND CHARCOAL TRIO

It is seen that the hardwood distillation industry has made considerable technical progress in the last seven years, but there are still many technical details which require further study and many other points that require careful attention if the industry is to continue its present importance. The hardwood distillation industry is peculiar in that it produces three marketable products which have been of about equal importance to the industry. At one time acetate of lime may seem to be the most valuable and important product, and then methanol takes first place. The third product, charcoal, varies somewhat in demand, but in any case it makes a good third in the line. Persons frequently ask what is the cost of production of methanol or of acetate of lime, without thinking that it is an impossibility to figure the cost of production of one of these products in a practical commercial way without including the other products. It would be unreasonable to charge the entire cost of production to either product alone, and at the same time it is difficult to apportion the proper costs of the three materials. If for any reason there is a drop in the price of one of the three products and if this drop in price brings the total cost of production above the price of the products, it is necessary that some other of the three products increase in price sufficiently to make up the difference. This is probably the explanation of the rapid increase in price of methanol shortly after the Government restrictions were removed from this product and acetate of lime. The demand for acetate of lime had fallen off, and there were large stocks on hand. When the price of this product decreased for these reasons, the price of methanol had to advance in order to keep the value of the three products above the cost of production.

During the war there was such a demand for acetate

and acetone that the hardwood distillation industry could not supply the required production, although previous to the war practically all acetic acid made for industrial purposes was obtained from wood as the original raw material. Several new processes for the manufacture of acetone and acetic acid were developed, and some of them were put into commercial operation. Two of these new processes are even now in operation, apparently in successful competition with similar products made from wood. This means that the monopoly of the hardwood distillation industry in acetone and acetic acid is broken and that its strength will now lie in its monopoly in methanol.

Up to the present time no promising method for the synthetic manufacture of methanol has been developed, but five years ago we could have said that no promising method for the synthetic manufacture of acetic acid had been developed. If the demand is great enough and if the price is high enough, there will be a great incentive for development work on a synthetic methanol or formaldehyde. If some process is developed which can compete with methanol from wood the hardwood distillation industry will be in a very precarious condition. It seems desirable, therefore, that the industry make efforts to remove this incentive by greater production and lower price for methanol and that it build itself up to the very highest efficiency in order to meet competition of this kind when it does arrive.

CENTRAL RESEARCH ORGANIZATION

There are several points in which the industry can build up its general efficiency in order to meet this situation. One general method which has been used with very good results in other industries is the development

HARDWOOD DISTILLATION PLANT

of a central technical control or a central research organization. Any new method developed by one of the units of the industry should be made known to the others, and the details of costs and profits should be made available so that the other plants can determine whether the new development is desirable under their conditions of operation.

In connection with such a system a few technical men should be in the employment of the industry as a whole, in order to study these new developments and report on the results obtained. This is the simplest method of obtaining and applying new developments, but it is of course very slow in comparison with the operation of a central research organization, in which new ideas would

⁶Trans., A.I.M.E., 1916, p. 1,387. CHEM. & MET. ENG., vol. 20, No. 11, June 1, 1919, p. 538.
⁷J. Ind. Eng. Chem., vol. 12, p. 684 (1920).

be actively sought for and investigated. In the end the more extensive research organization is really the most efficient, because it prevents the units of the organization from duplicating new work and it assures more careful and complete research work on new problems.

There is also a very good field along the line of general efficiency in the operation of the plant. Such simple things as pipe fitting, control of the temperature of the condenser water, and proper methods of firing the retorts and boilers may make a very large difference in the cost of production.

HIGHER YIELDS TO BE SOUGHT

It is also possible that the time has come when the attention of the industry should be directed toward increasing the production from a unit quantity of wood rather than increasing the capacity of a plant of unit cost. The cost of wood and the cost of labor are both very high at the present time and will probably continue much higher relatively than they have been previously. On this account any labor-saving device or any method by which more products can be obtained from a cord of wood should be very seriously considered. It is possible that a complete change in the design of the retorts and in the general method of handling the wood would give greatly increased efficiency under the new conditions of increased cost of wood and labor, although this change might have been entirely impractical under the old conditions. The practicability of preparing artificially dried blocks about 5 in. in length may encourage the introduction of an idea which has been several times suggested but never put into practice. This is the idea of a vertical continuous retort in which the temperature increases as the wood descends. Such retorts should be very economical of fuel, since the flue gases from the lower chamber of the retort could be used for heating the higher and cooler portions. As the operation would be continuous, the control of the temperature could be made very simple and each part of the retort could be kept at a nearly constant temperature.

Methods for the destructive distillation of sawdust would also be of value, though they would not be likely to have a very great influence on the industry, since the localities where large amounts of hardwood sawdust would be available are not very numerous. Unless larger sized pieces of wood, such as slabs and edgings and possibly some tops and limbs, were ground up for use in the process, it would be difficult to obtain enough small-sized material to run a commercial plant.

CONTROL OF PRODUCT YIELDS

Some experimental work started at the Forest Products Laboratory a few years ago and now in progress again after a few years interval has indicated the possibility of changing the yields of various products by the addition of certain chemicals to the wood previous to distillation. It has been shown that the presence of a small amount of phosphoric acid prevents the formation of any tar; and it would, therefore, be possible to start the refining of the pyroligneous acid without a preliminary distillation in order to remove the tar. This would result in considerable economy of fuel.

Some recent experiments along this line have indicated that a small proportion of certain chemicals tends to increase the yield of methanol very considerably but with a small decrease in the yield of acid. At the

present time, when there is a great demand for methanol and only a slight demand for acetic acid, a process of this kind might be very desirable. It is not impossible that further work along these lines might develop methods by which the relative yields of the different products would be controlled according to the markets, so that when methanol, for instance, was in great demand the yields of this product could be increased, possibly at the expense of some other product. At the present time there are no indications of a chemical or catalyzer which could be used to increase the yield of acid possibly at the expense of the methanol.

There is a great deal of work to do in research and in plant control and organization, in order to keep the wood-distillation industry generally efficient and progressive and make it able to meet the competition which has already arisen in regard to one of its products. Although this industry has made great technical advances in the last few years, it cannot rely on past records but must continue to advance at even increasing speed.

Tannins and Dyewood Extracts

H. O. Chute in a paper read at the Montreal meeting of the American Institute of Chemical Engineers on the Progress in Dendrochemistry stated that:

The discovery of the use of wood extracts for tanning and dyeing is prehistoric. Many of the most savage and primitive tribes have knowledge of their use.

In late years the United States has produced about 200,000,000 lb. tanning extract annually and has imported—mainly from South America as quebracho extract—about as much. Much bark, as hemlock and oak, is also used for the production of leather.

Someone has said that anyone who can make a pot of tea can make a wood extract. In an earlier day this was perhaps so, but modern methods have been introduced into this industry.

The most approved practice in the United States is to grind the woods or barks, etc., and extract in a diffusion battery under pressure. This necessitates the use of copper to give the strength and resistance to the acids which are present. Probably the most popular extractor or diffusion cell is about 5 ft. diameter and 12 ft. long, slightly enlarged toward the bottom so as to allow of quick discharge of the exhausted chips. The bottom is hinged and is the diameter of the cell and, on opening, the charge drops out to a conveyor which takes the chips to the boilers for fuel. These usually furnish all the steam necessary to the works. Each wood requires a different temperature and pressure and treatment to get the best extract. Some woods, such as quebracho, are best extracted by adding some SO_2 to the liquor to dissolve the more refractory tans. Some extracts, like logwood, are oxidized, the oxidized logwood extract being called "hematine," and this is used for leather dyeing and where oxidation after applying cannot be used. On the other hand, the unoxidized logwood is preferred where bichromate mordants are allowable.

All the different woods and tannins differ in containing various other constituents. Some contain glucose, which, by fermenting, produces an acid liquor which is desirable at certain stages of the process and for certain leathers. Others contain much coloring matter and give colored leathers which are desirable or not according to their purpose. Those extracts which will not ferment, such as chestnut and quebracho, are used in connection with such fermentable extracts as hemlock, etc., or are used in the later stages of tanning.

The woods most commonly used in America for tannin extracts are hemlock and chestnut.

What seems to be a purely American invention is the production of a tannin from the chipped wood and a soda pulp from the extracted residue, thus utilizing both the fiber and tannin in the wood.

Putting the Paint and Varnish Industry on a Scientific Basis

During the Last Twenty-five Years Empiricism Has Been Rapidly Replaced by Scientific Control in the Paint Industry, Due Mainly to the Initiative of American Chemists — Research in Varnish Industry Has Dealt Chiefly With Raw Materials

BY MAXIMILIAN TOCH*

THE manufacture of paints is purely scientific, and although pigments have been made for many centuries no scientific control was observed until about twenty-five years ago.

The manufacture of varnish is partly empirical and partly scientific, but within the last fifteen years the manufacture of varnish has emerged from the rule-of-thumb to the semi-scientific state.

No scientific work of any consequence was done in Europe on paints and varnishes until American investigators had already established that industry on a sound basis, and as recently as 1906 it was evident that there were only four or five concerns in the United States which manufactured paints and varnishes that had chemists in their employ.

I do not include in these half a dozen concerns that employed analytical chemists to test the purity of the materials which they bought, but it was well known at that time that there were only a few of us who knew how to analyze mixed paint or had even a working knowledge of the composition of an oil so well known as linseed oil.

Prior to 1906 the most impossible and worthless mixtures paraded under the name of paint and it must be said to the credit of the State of North Dakota that Prof. Ladd was authorized to make an analysis of the various paints and pigments which were for sale, in order to protect firms from buying adulterated and useless materials in that state. There were many innocent errors made in the promulgation of the law in question, but the results worked out admirably, and today almost every paint and varnish manufacturer of the United States either employs a chemist directly or seeks scientific assistance indirectly.

SCIENTIFIC STATUS OF INDUSTRY IN 1906

There was at that time no literature on the subject, and I had been collecting the results of my own work since 1900, with a view to publishing a book which I intended to call "The Chemistry and Technology of Mixed Paint"; so when the State of North Dakota passed a law which broadly amounted to labeling all paints excepting those of certain composition, all paint manufacturers of the United States attempted to defend it; and the peculiar condition became apparent that men like A. H. Hooker, of Heath & Milligan; G. W. Thompson, of the National Lead Co.; Prof. Sabin, of Edward Smith & Co.; Dr. C. B. Dudley, of the Pennsylvania R. R., and I were the only chemists in the United States who had at that time any knowledge of the chemistry of paints. There were, perhaps, three or four more, like Parker McIlhenny, C. W. McKenna and others who did private work, but when it came to testifying on the witness stand as to an

exact knowledge of the composition of paints, the value of such materials and an expert knowledge of the manufacture of the finished product, I was the only man, at that time, in the United States who qualified as a chemist and a manufacturer.

This was less than fifteen years ago, but since that time hundreds of able men have been engaged in work on this subject; and today lectures are delivered at our various institutions of learning, both here and abroad, so that what was empirical and regarded as exceedingly valuable, from the standpoint of secret process, is today common knowledge published for the information of all.

CHANGE IN ATTITUDE TOWARD CERTAIN PRODUCTS

During that famous trial, lithopone, regarded as a useless and cheap pigment, was brought to the attention of the paint industry, and its manufacture rose until today it is third in the list of white pigments, corroded lead and zinc oxide still taking the lead.

Chinawood oil, which only a very few knew how to manipulate, was given its proper place as a paint and varnish material, and today it is for certain purposes far more valuable than linseed oil.

Chemical and physical tests have been devised for the identification of pure turpentine, and that solvent was shown to be only a solvent and no better in the manufacture of paint than several of the petroleum solvents which evaporate completely.

I remember a very interesting experience I had more than twenty-five years ago on my first trip South to the turpentine stills, when I saw that it was the custom to add a barrel of kerosene or benzine to nine or ten barrels of the sap of the pine tree to "start the distillation properly," as some of these turpentine distillers put it, with the result that when I arrived back home and tested turpentine for specific gravity and polymerization by means of sulphuric acid, I came very nearly establishing wrong data because of this custom among the turpentine distillers.

It is very difficult for me to write a short history of the scientific development of the paint and varnish industry without repeating myself, because I have so often told of my experiences, both orally and in writing, but it does no harm to repeat one or two of my experiences for the benefit of those who wish to profit thereby.

RULE-OF-THUMB METHODS UNPROFITABLE

Once a well-known color manufacturer who, although a competitor, was a very warm friend confided to me that in the manufacture of chrome yellow he could never make any money; and he asked me to investigate and find out whether there were any leaks in his factory that his color-maker could not discover. I found, on going through his plant, that he had no chemist and that his color-maker was an ignorant man, practical to

*Professor of Industrial Chemistry, Cooper Union, N. Y.; member of the firm of Toch Bros., New York.

the last degree, but unscientific in every respect, and that he had a little note-book of formulas, one of which read as follows:

"To one pail of nitric acid add 50 lb. of litharge; then pour this in a barrel and fill it with water. Then take 100 lb. of bichromate of potash, and mix them, and you get pure medium chrome yellow."

On investigating further I found other formulas in which my friend used sugar of lead; that the color-maker dissolved a certain number of buckets of this material and added it to a certain number of buckets of bichromate of potash, with the result that the wash water showed a very large excess lead acetate which went into the sewer, and it was very easy to indicate where the loss took place; and after correcting these glaring errors I had the satisfaction of installing a chemist in the plant, and from that time on the color works in question became profitable.

LITTLE CHANGE IN VARNISH TECHNOLOGY

The manufacture of varnish was described four hundred years or more ago by an Italian named Cennini, and to this day the manipulation, the kettles and the tools used have scarcely changed, with the one possible exception that we know more concerning the raw materials which we use; we have been able to utilize products which were formerly regarded as adulterants; and every oil and resin used in the paint or varnish industry whose constants are indicators of its eventual physical characteristics we are familiar with.

The advent of chinawood oil has brought about a change, and I am unafraid to admit that, while I despised and discouraged the use of it in my own factory, I am now a firm believer in it until something better can be discovered.

Let us remember that fifteen years ago chinawood oil was condemned because its physical characteristics were compared with linseed oil, which shows us that it is a mistake to take a new material and judge it by an older one. Raw linseed oil, as everyone knows, dries with the aid of a drier, and when suitably mixed with the proper pigments forms a film which lasts anywhere from three to eight years, even under extreme exposure.

Raw chinawood oil, on the other hand, no matter what it is mixed with, dries with an opaque, brittle, crystalline film, which is neither flesh nor fowl. It polymerizes or solidifies when heated for twenty minutes to 420 deg. F. (216 deg. C.). It is difficult to manipulate and in unskilled hands it is a failure. But when 4 lb. of chinawood oil is heated with 1 lb. of rosin that has been partly or wholly converted into a resinate of lead or similar compound, the heat can be carried up to 600 deg. F. (315 deg. C.) without danger of the polymerization of the oil, and a varnish is obtained which, while fairly high in acid number, possesses more remarkable qualities than the best kauri linseed oil varnish ever made. This sounds strange, but it is true.

Of course, to those skilled in the art it is known that this resultant fusion of 5 lb. just mentioned must be diluted with equal quantities of turpentine or turpentine substitute, and the film so produced will not turn white after it has been permitted to dry thoroughly, even though the test sample is placed in water for weeks. When I made my first experiments along these lines I did not use the material as a varnish, but I used it as a paint oil. Of course, lead and zinc could not be used as bases, because chemical union would take place, and the

compound, which I called a tungo resinate of lead or zinc, was formed, which was a viscous, ropy, gelatinous material, physically unfit for making paint ready for use. But, if the proper pigments were selected, such as graphite, lithopone, red oxide and blanc fixe, a paint could be made which remained in suspension for a long time.

As many know, I do not rely upon laboratory experiments for the finding of my conclusions; but in 1915 and 1916 I made several hundred gallons of various colored paints, omitting linseed oil entirely as a vehicle, and substituting for it a varnish made from rosin and chinawood oil, and these paints I applied to wooden structures on the Atlantic coast which were from 100 to 500 yd. distant from low tide and subject, therefore, to the heavy sea fogs of that locality. In comparison with these tests there were a number of smaller buildings painted with various mixtures of lead and zinc and linseed oil, and the conclusions arrived at were that the gloss and hardness of the resulting film, after three years, was as good for the rosin : chinawood oil mixture as for the linseed oil paint, with this exception—that the rosin : chinawood oil paint left a better surface for repainting.

PRESERVATION OF ENGINEERING MATERIALS

Much work has been done on the preservation of engineering materials by means of paint; and whereas we formerly thought that all paints protected, we now know that some pigments produce corrosion and others retard it to a remarkable extent.

Paints have many uses, both decorative and protective, which frequently give them a value that is inestimable, such as, for instance, the modern flat wall paints for the interior of buildings, which can be washed and which are far more economical than the dust-collecting wall papers and hangings formerly used.

PAINTS FOR CONCRETE SURFACES

It has been said that this is the concrete age, where portland cement is taking the place of flammable and other perishable building materials; and it is only within the last seventeen or eighteen years that methods have been devised for the coating of concrete for exterior and interior with paint materials, and these methods have been worked out purely on a scientific basis. Paints are usually made of a saponifiable base, and concrete is basic in its nature; therefore, the average oil paint is readily destroyed, and that accounted for the well-known dictum that concrete cannot be painted. But this has been completely overcome through scientific investigation, so that concrete structures of all kinds may be preserved against the acid fumes with which they may come in contact and the aqueous and other disintegrating influences which may tend to abrade them.

It is not my intention to indicate that all paint manufacture has been placed upon a scientific basis, but the enormous strides many have made in the last fifteen years and the many scientific investigations that have been made indicate that this industry will eventually be one in which empiricism will be entirely eliminated, and the credit for most of the investigation that has taken place must go entirely to America, for Germany, with all her much-heralded chemical knowledge, did very little if anything toward the scientific investigation or improvement in the manufacture of paint and varnish.

Alloys of the Past and Present

**A Review of the Recent Developments in the Production of Pure Metals, Ferro-Alloys, Bronzes and Brasses and of the Increasing Uses for the Less Common Metals and Their Alloys—
Research Suggestions for the Production of Special Alloys**

By COLIN G. FINK*

CENTURIES ago pure metals as derived from their minerals were practically unknown. There are a few noteworthy exceptions, such as the pillar of pure iron at Delhi, now over 1,600 years old. But in general the metallurgical processes of the past were so crude that it was not possible to produce, say, pure copper or pure nickel or pure zinc, nor to cast alloys of constant composition. The copper of the Greeks and of the Romans never even approached the "International Annealed Copper Standards" of today.

Within our present era—in particular within the latter part of the nineteenth century—metallurgical investigations were carried out here and abroad with a view of producing metals of "absolute" purity. It was found that the elimination of the last traces of impurities in copper brought about a very decided increase in the electrical conductivity of the metal. Traces of certain foreign metals in gold when removed resulted in a very malleable and ductile metal.

It was a natural inference that in general metals of 100 per cent purity were the most desirable. Metallurgical processes were being rapidly developed and improved upon. Electrometallurgy became of ever-increasing importance. Metals could be produced of a purity never before attainable.

However, it wasn't very long before we found that "100 per cent purity" was not always desirable. For example, in the case of silver a product was obtained by electrolytic refining methods which was extremely pure, purer than "Sterling" and exceptionally soft and malleable; but for actual service this "100 per cent pure" silver showed very poor wearing qualities and accordingly had to be "doped" with copper and other impurities to bring it back to "Sterling" grade.

Pure nickel could not be rolled into sheets and drawn into wire without excessive breakage. It was necessary to add a small percentage of manganese to render nickel workable. Iron containing small percentages of copper or larger percentages of silicon or chromium corroded less than pure iron. Aluminum containing a little manganese was in general preferable to pure aluminum. Tungsten with $\frac{1}{2}$ to 1 per cent thorium makes a better filament than 100 per cent pure tungsten. Specifications today not only point out the impurities the metal or alloy must not contain but include various foreign elements with limiting percentages that must be present in the product to be acceptable.

FERRO-ALLOYS

The advent of the electric furnace and the introduction of commercial electrolytic cells with fused salt baths, more than any other factors, brought about a

sudden spurt in the development of our modern alloy and rare metal industries. The most remarkable advances have been made within the last twenty to twenty-five years. The electric furnace and electrolytic aluminum have made possible the production of ferro-alloys of a tenure and purity never before attained by the ordinary blast or hearth furnaces. It is very clearly demonstrated at the Chemical Exposition that a number of our capital industries, such as the machine industry, the electrical industry and the automobile industry, are largely if not wholly dependent upon electrolytic and electrothermic products and processes. Chief among these products are the ferro-alloys—ferromanganese with 78 to 82 per cent Mn, a valuable deoxidizing and recarburizing agent; ferrosilicon, up to 90 per cent Si, more effective than ferromanganese for eliminating gases in steel and other alloys and for the manufacture of silicon iron used in electrical apparatus; ferrovanadium with 30 to 40 per cent V, an indispensable addition to steels for the automotive industries where high tensile strength and resistance to constant vibrations are demanded; ferrochrome with 30 to 60 per cent Cr, for chrome-nickel and chrome-vanadium steels, armor plate, stainless steel, tool steels, etc. (according to C. B. Gibson, over 50 per cent of the chrome-vanadium steels are absorbed by the manufacturers of automobiles); ferrotungsten with 70 to 80 per cent W, for high-speed steels and magnet steels; ferrotitanium with 15 to 25 per cent Ti, a most valuable scavenger in the making of steel for rails and high-grade castings; ferro-uranium, for tool steels; and ferromolybdenum, one of the latest alloys to come into popularity, for crankshafts, gears, springs, etc.

ALLOYS FOR TOOLS

Rapid strides within recent years have been made in the development of alloys for tools. Modern high-speed tools, with 400 to 700 per cent efficiency as compared with the old carbon steel tools, were of inestimable value during the war when the element of time was a very important factor; and today, with labor and material prices soaring skyward, there are few that can afford to use an ordinary carbon-steel tool. The introduction of vanadium into the original tungsten steels greatly improved their quality and endurance.

Systematic investigations into the composition and nature of tool steels have lately been published by J. A. Mathews of Syracuse, K. Honda of Japan, R. C. McKenna of Pittsburgh, Dean J. O. Arnold and Fred Ibbotson of the University of Sheffield and others. A detailed discourse on tool steels by A. J. Langhammer of New York recently appeared in this journal.[†] He cites, as average composition of modern high-speed tool

*Director, Research Laboratories, Chile Exploration Co.
†L. T. and E. A. Richardson, *MET. & CHEM. ENG.*, vol 15, p. 450, Oct. 15, 1916.

[†]*CHEM. & MET. ENG.*, vol 22, pp. 829, 889, 939, 969.

steel, tungsten 16 to 18 per cent, carbon 0.60 to 0.70 per cent, vanadium 0.75 to 1.05 per cent, chromium 3 to 4 per cent.

The introduction of the chrome-molybdenum-cobalt steel *Stellite* by Haynes, of automobile fame, has given rise to exhaustive tests, in particular in Canada and England. Arnold, in referring to this and similar steels, terms cobalt a stabilizer of molybdenum. *Stellite* alloys have gained a wide use as lathe tools, but many of these contain tungsten in place of molybdenum. The high-speed steel industry is still in a development stage, and as regards the proper intelligent operation of these special tool alloys comparatively few machine shops are fully conversant with the grinding, the best operating speed, the correct methods in heat treating, etc. Unfortunately there is a different heat treatment prescribed for each brand of tool steel. Aside from this it is usually difficult to get a machinist to realize that tool steels of today require different heat treatment from ordinary carbon steels.

ACID-PROOF ALLOYS

Most important among the acid-proof alloys are the ferrosilicon alloys containing from 10 to 15 per cent Si. As every visitor to the Exposition will concede, these alloys have passed beyond the experimental stage. Large vats, mixers and boilers for corrosive liquids have been installed in industrial plants all over the

FIG. 1. ORDINARY COBALT

world. Furthermore the 13 per cent ferrosilicon alloy has been found superior to lead and to magnetite as an insoluble anode in electrolytes containing not only sulphuric acid but nitric as well. Next to ferrosilicons in industrial importance as non-corrosive alloys are the ferrochromes. They are chemical corrosion-proof but not very electrolytic corrosion-proof. Exhaustive tests have been carried out at laboratories in Niagara Falls and in New York. A. W. Clement in his patent (U. S. 1,333,706) recommends an alloy of 60 per cent chromium, 40 per cent iron for acid-resisting pipes

and valves. Nickel-chrome alloys are giving very satisfactory service not only as acid-resisting material—for example, for dipping baskets in plating and pickling operations—but also as a material resisting oxidation and destruction at high temperatures. Accordingly, annealing boxes made of nickel-chrome are far outlasting the older ordinary iron boxes.

THE BRASSES AND BRONZES

The brasses and bronzes are among the very oldest alloys in metallurgy, but it is only within the last generation that their composition and properties have been thoroughly investigated and stringent specifications drawn up for more than two dozen different grades and qualities, depending entirely upon the use to which the brass or bronze is to be put. The last two or three years have seen a complete conversion in the brass melting art from gas- or oil-fired furnaces to electric furnaces. The reduction of spelter losses is only one of the many advantages gained. A section of this year's Exposition will be devoted entirely to brass-melting electric furnaces. Types of the direct-resistance, the indirect-resistance and the arc type will be on display. Electric melting of brass costs about half that with the older combustion furnaces.

The introduction of aluminum among the cheaper metals has given rise to innumerable investigations on aluminum alloys. Many of these alloys, on account of their light weight, have been found indispensable in airplane construction. One of these airplane alloys contains 3 per cent copper and 13 per cent zinc, the remainder being aluminum. As the copper content is increased the hardness of the alloy is increased. Duralumin contains approximately 94 per cent Al, 3.7 per cent Cu, 0.6 per cent Mn, 0.25 per cent Zn, 0.43 per cent Mg, 0.6 per cent Si, 0.5 per cent Fe. It has a tensile strength of 38 kg. per sq.mm. and a Brinell hardness of 90.* An alloy which is an improvement on the well-known "Coney Island gold" alloy (90 to 91 Cu + 9 to 10 Al) has recently been patented by S. Shigeta (U. S. Pat. 1,319,537). It contains about 80 per cent copper, 10 per cent aluminum, 5 per cent molybdenum and 5 per cent tungsten. In color it resembles gold very closely and can be worked into thin sheets. The alloy corresponding to the formula Al₁Mg₁ (about 46 per cent Al) was carefully investigated by Waltenberg and Coblentz of the Bureau of Standards,† and they found that the polished surface possessed a very high reflectivity and was suitable as a mirror providing the surface can be protected from tarnish.

BEARING ALLOYS

According to W. K. Frank‡ a typical bronze bearing contains 9.5 per cent Pb, 10 per cent Sn, 79.7 per cent Cu and 0.8 per cent P. This bronze has a Brinell hardness of 60 and a compression of 0.25 on a 1-in. cube with a load of 100,000 lb. per sq.in. High lead alloys are plastic but wear rapidly and are difficult to produce uniformly. The best bearings have the greatest hardness compatible with the required plasticity. Of special interest are the Frary bearing alloys. One of these, for example, contains about 97 per cent lead and 3 per cent barium plus calcium. These alloys have given remarkably good service, are uniform in

*L. Guillet, J. Durand and J. Gallibourg, *Compt. rend.* vol. 169, p. 508.

†*Bu. Stand. Sci.* paper 363, 1920.

‡*Iron Age*, vol. 105, p. 943 (1920).

quality and readily reproduced. As compared with ordinary lead, the alloys are hard and when struck with a hammer emit a clear metallic ring. The alloys are now manufactured on large scale at Keokuk, Iowa.

LOW-TEMPERATURE COEFFICIENT ALLOYS

Constantan, a copper-nickel alloy with a very low-temperature coefficient, has received renewed attention within the last few years and exhaustive treatises have been published by Hunter and Bacon, F. E. Bash, D. W. Gray and others. Gray found that the addition

FIG. 2. CARBON-FREE COBALT

of manganese increased the specific resistance and decreased the temperature coefficient. One of his best alloys has a specific resistance of 70 microhms per c.c. and a temperature coefficient of practically zero. It is composed of approximately 55 parts of copper, 45 parts of nickel and 10 parts of manganese. For thermocouples Bash¹ recommends the following proportions of the elements in constantan: Copper 53.18 per cent, Ni 45.71 per cent, Fe 0.26 per cent, Mn 0.61 per cent, C 0.17 per cent, Si 0.09 per cent, and S 0.02 per cent.

INCREASING USES FOR THE LESS COMMON METALS

Of the less common metals zirconium has been one of the most popular lately and there have been at least half a dozen laboratories, both here and abroad, investigating the properties of the metal, its alloys and other compounds. The laboratory of the Bureau of Mines at Golden has been turning out some very pure metal. At Pittsburgh zirconium steels were tried out, but details have not as yet been published.

Thallium, manufactured in limited quantities at Denver, has found application as the "getter" thallos chloride in tungsten lamps. It is one of the very few metal chlorides whose lower or "ous" state is more stable than the higher or "ic" state. A very interesting recent application of thallium is in the "Thalofide Cell,"

whose active principle is an oxysulphide of thallium. The cell is a new light reactive resistance of great sensitivity.² The electrical resistance drops 50 per cent on exposure to $\frac{1}{4}$ -ft. candle. The cell is more sensitive than the selenium cell, especially on exposure to very low light intensities.

Calcium is now manufactured on a commercial basis and has found a definite and valuable application in small rectifiers and similar electrical apparatus. The Frary lead-calcium alloy has been referred to above.

The Department of Mines of Canada has carried out exhaustive researches on the alloys of cobalt. Cobalt steels have been made equal in many respects to the best tungsten steels. An interesting alloy which shows a very high degree of ductility is composed of about 20 parts of cobalt and 80 parts of nickel. Rods $\frac{1}{2}$ in. in diameter can be rolled and drawn down to $\frac{1}{16}$ in. in diameter without intermediate annealing.³

SUGGESTIONS FOR RESEARCH

There are a number of metals whose alloys have been only partly investigated. Among these might be mentioned tantalum, columbium, uranium and molybdenum, all of which are obtainable in fairly large quantities and are not, strictly speaking, rare metals such as gallium and scandium.

The tantalum filament appeared on the market in 1905, but within a few years it was superseded by the more efficient tungsten filament. However, a world search for tantalum mineral deposits had been instituted by the Siemens & Halske Co. and a bountiful supply of the metal was assured. There are large deposits in Australia and the United States.

Tantalum is a metal whose properties have been carefully investigated, its manufacture at one time being carried out on a commercial basis, but today the metal is almost unknown and forgotten. Considering a few of the remarkable properties of tantalum, such as the high melting point (2,900 deg. C.) high ductility and tensile strength, insolubility in acids except hydrofluoric, the metal certainly deserves further study and research. Tantalum alloys readily with nickel, cobalt, iron and other metals.

Uranium, molybdenum and zirconium have been investigated so far mainly as addition metals to steel. There is every possibility that one or all of these metals will form a valuable constituent of iron-free alloys. An alloy of molybdenum and cobalt has the same coefficient of expansion as glass, can be drawn into wire and makes a perfect seal in glass.

Another field of alloy research is the production of alloys absolutely free from carbon, sulphur and phosphorus. The author's investigations on ferronickel and on cobalt metal and its alloys have demonstrated rather strikingly that the properties of the metals and alloys undergo a decided change upon the complete elimination of the above three impurities. In the accompanying microphotographs Fig. 1 is a sample of commercial cobalt melted in the presence of carbon, and Fig. 2 is the same sample after heat treatment in hydrogen. After hydrogen treatment, cobalt, its alloys with nickel and similarly ferronickel are almost as soft as copper. The disappearance of the carbon is readily recognized in the microphotographs.

BALTIMORE WORKS, U. S. INDUSTRIAL ALCOHOL CO.

Science and Industrial Alcohol

Development of the Alcohol Industry Caused by Chemistry and Allied Sciences—Production Involving Raw Materials, Synthesis and Fermentation—Recovery, Involving Distillation, Rectification and Purification—Byproducts Obtained and Unsolved Problems

BY BURNELL R. TUNISON

THE industry of producing alcohol for manufacturing purposes is one of the older fields of activity with which science and particularly chemistry have been concerned. It has been considered by many that the process of alcohol production and recovery has reached a high degree of perfection. That being the case, it may be of assistance to some to note the development that has been made, the obstacles overcome and the problems which still remain unsolved.

Alcohol as such has been known and used for a great many years and even centuries prior to the study of alcohol as such and its properties. Even as early as 500 to 1000 B.C. the natives of India and China knew that by distilling certain mixtures a beverage could be obtained which exhibited marked properties as a stimulant. The Greek alchemists from the first to the fourth century A.D. learned the use of stills for simple distillation and the elements of condensation. About the twelfth or fifteenth century alcohol became recognized as a stimulant and curative agent in disease. Not until the nineteenth century, however, was the industrial use of alcohol developed. Up to that time very little progress in the art of distillation had been made, the apparatus was crude and the alcohol produced was very dilute, in addition to containing other alcohols and fermentation impurities which made it unsuitable for most industrial purposes.

The progress made in the alcohol industry may be noted from two points of view—namely: (1) The production, involving the raw materials and the fermentation or synthesis, and (2) the recovery, involving the distillation, rectification and purification.

RAW MATERIALS

Probably the first materials used for the production of alcohol were the fruits and fruit juices which were universally used as beverages. As more was learned about the constitution of alcohol and the type of compound from which it was being made, the grains came into use. During the eighteenth century the question "What is alcohol?" led to considerable work being done

to determine its actual composition and a study by the foremost scientists of the times to determine its process of formation and the nature of the compounds from which it was formed. Since the eighteenth century this constant application of scientific truths to this industry has made it safe to say that at the present day it is possible to utilize any material containing starch or sugar and many products of cellulose as a raw material for the production of alcohol. Thus the factors at the present time which determine the raw material which shall be utilized for alcohol manufacture are largely economic, the technical difficulties having been practically solved. It is true that in the use of many materials there are possibilities of much improvement in the matter of yields and efficiency of handling the process materials, and these are some of the many problems which are at present receiving the attention of experts.

At the present time the most important raw material for the production of alcohol is cane or black strap molasses. It is one of the easiest of all the raw materials to handle, requiring only dilution and acidification before fermentation. Next to molasses in importance as a raw material are the grains, corn probably being used most extensively. The choice of a raw material for alcohol production is dependent largely upon economic conditions, consequently they differ in different countries, nearly every country using a different product as a raw material. For example, Germany is noted as a country where potatoes are grown for this purpose, France uses grain and sugar beets as well as beet molasses, the United States molasses and grain chiefly. The Philippine Islands use nipa palm, China uses large quantities of rice, England is beginning to use mawra flowers, mahua and similar plants. Yucatan uses sisal waste and India uses dates and date palms.

Where we have so many possible sources of raw materials, those who are charged with the technical control of the alcohol plants of the world are very likely not to take into consideration enough of the factors or products which should be given attention. In most countries there are at least several raw materials which

should be considered. This is especially true of those plants which thrive in tropical climates. As a general rule these plants grow very rapidly and thickly over large areas and the cost is merely that of cutting and transportation to the point of utilization. For example, the nipa palm (*Nypa fruticans*) is used in the Philippines. *Commerce Reports* (July 12, 1920, page 212) states that alcohol can be made from this material for approximately 20c. per gal. There is a sufficient quantity available to produce approximately 50,000,000 gal. of alcohol per year. The present production of alcohol from this source amounts to only 2,500,000 gal. per year.

In most tropical countries the cassava and arrowroot grow very luxuriously and are excellent raw materials. They compare very favorably with potatoes as to starch content, containing approximately 25 per cent starch and

MOLASSES STORAGE—SEVEN TANKS—2,000,000 TO 3,000,000 GAL. EACH

from 4 to 6 per cent of fermentable sugars. Cassava tubers are about 8 to 10 lb. in weight. An acre of ground producing average cassava, it is stated (*Press Bulletin* 63, Bureau of Science, Manila, 1917), will yield approximately ten tons of tubers giving about 5,000 lb. of extractable starch, which is more than double the yield of the same area growing an average crop of potatoes.

An endless number of examples of raw materials might be given, but the above are typical. More thought should be given to the matter of raw materials for fermentation by all those engaged in the manufacture of industrial alcohol.

Two other sources of raw material for the production of industrial alcohol should be mentioned, as they will very probably be developed to some extent in this country. These are waste sulphite liquor and wood waste. The former material is available in only relatively small quantities, but in that it does contain fermentable matter and is a waste product it will probably be utilized to greater extent than at present. Wood and wood waste have been experimented with for many years, but normal conditions have not become such as to make possible the production of alcohol from this source on an extensive scale at a price which can compete with alcohol produced from the other sources.

SYNTHESIS OF ALCOHOL

The first chemical synthesis of alcohol is usually attributed to Berthelot. In 1854 he obtained it by absorbing olefiant gas in sulphuric acid, diluting the product and distilling it. It is also claimed that Hennell (Simmond's "Alcohol," p. 10, 1919) in 1827 succeeded in identifying ethyl sulphuric acid in a quantity of sul-

phuric acid into which Faraday had passed olefiant gas. Hennell in 1828 is supposed to have distilled this ethyl sulphuric acid with water and a little sulphuric acid and obtained sulphuric acid and alcohol.

Because of the relative cheapness of the raw materials for fermentation and the ease of making them very little attention has been paid to the various methods of producing alcohol synthetically. In recent years, however, where unusual conditions exist alcohol has been produced synthetically on a commercial scale. In localities where raw materials for fermentation are not abundant or where cheap power is available, such as are the conditions in Norway or Switzerland, alcohol is produced synthetically from acetylene. Calcium carbide is produced in the electric furnaces and acetylene from the carbide by the action of water. Two methods are used in the production of alcohol from acetylene:

1. Acetylene is hydrogenated by catalytic means and ethylene is produced. The ethylene is dissolved in sulphuric acid, and alcohol and sulphuric acid are formed upon saponification.

2. Acetaldehyde is produced catalytically from the acetylene. The acetaldehyde is oxidized to acetic acid or reduced to alcohol by means of catalyzers. Consul W. O. Kent of Berne, Switzerland, has described (1917 *Commerce Reports* 102, p. 426) an equipment for the production of 7,500 to 10,000 tons of alcohol per annum by the above means.

One of the newer developments for the production of industrial alcohol is its production from the waste gases from coal carbonization plants. The gases given off during the coking of coal contain appreciable quantities of ethylene. This ethylene may be separated, purified and dissolved in sulphuric acid and ethyl sulphuric acid formed. This may be readily converted by saponification to alcohol and sulphuric acid. Extensive experiments have been carried on in England with the result that it is claimed by H. F. Grady (1919 *Commerce Reports* 219, p. 1,460, also 1920, 21, p. 506), who describes the operation of a plant at the Skinningrove Iron & Steel Works, that 1.6 gal. of 95 per cent alcohol can be obtained from the gases produced by each ton of coal carbonized. The report of the British Inter-Departmental Committee on the production and utilization of "power alcohol" states that sufficient ethylene can be obtained from the gas works and coke-oven gases of Great Britain to yield annually up to 150,000,000 gal. 90 per cent alcohol. Experimental work along this line is being done in the United States and our own production may soon be supplemented in this manner.

FERMENTATION

Although the production of alcohol from fruits and grains has been known since the beginning of the Christian era, it was not until the seventeenth century that any attempt was made to study the mechanism of its formation. In 1659 Wilis stated that a ferment was a body in a state of decomposition, its particles being in constant motion. This motion could be imparted to other bodies capable of fermentation. In 1689 the German physician and chemist Becker thought that fermentation was a process similar to combustion because of the similarity of the waste gases evolved. He also stated that only the different varieties of sugars were capable of alcoholic fermentation.

Liebig held that sugar was mechanically decomposed as a result of molecular motion, and that the yeasts

themselves were a product of the reaction and not its cause. Another theory explaining alcohol formation was that sugar was taken in as a food by the yeast, and alcohol and carbon dioxide were given off.

Berzelius regarded fermentation as a catalytic process.

Although, little by little, knowledge was acquired concerning alcoholic fermentation, very little progress was made until the beginning of the eighteenth century. On account of the microscopic size of the yeast cells, definite knowledge concerning them was not obtained until the development of the modern microscope. Although

60,000-GAL. ALCOHOL STILL

some of the earlier investigators had seen yeast cells, it was not until the microscope reached a high state of perfection that the fungi were carefully studied. During the early part of the eighteenth century much was learned concerning the specific properties of these microorganisms, their nourishment, growth, multiplication, etc.

In 1836 Cagniard-Latour (*Ann. Chim. Phys.*, 1838, vol. 68, p. 206) believed that from the results of his researches the yeast must be a living organism and was very probably a plant. Several other investigators about this time confirmed the conclusions that the yeasts were vegetable organisms and that they reproduced by budding or by spore formation.

Traube in 1858 explained that fermentation was due, not to the yeast cell itself, but to certain substances which were produced or secreted by these cells. However, this theory was discredited for many years.

The nineteenth century brought forth the famous controversy between Liebig and Pasteur as to the cause and mechanism of fermentation and the settlement of the question thus brought about. Liebig believed that the ferments were unstable nitrogen-containing substances, formed by the action of air upon plant juices containing sugar. These easily decomposable ferments he thought were in a constant state of degradation or decay. This decomposition imparted a corresponding chemical motion to the atoms of the sugar; and thus the sugar itself was decomposed with the production of alcohol. Pasteur eventually proved that the theory advanced by Traube was essentially correct. At the present time it is believed that the organisms capable of causing fermentation belong to one of the three groups of lower fungi—bacteria, yeasts or molds.

The bacteria attack not only carbohydrates but proteids and to some extent fats and other organic bodies. Frequently acids are produced by their action, but they are not producers of alcohol.

The yeasts which are the most important as producers of alcohol are monocellular organisms. The yeasts are the source of production of enzymes. These enzymes are the active fermenting agents. The yeasts are more or less imperfectly classified as to species, varieties and races. The various yeasts were carefully studied and classified by Pasteur, and since his time investigation has greatly extended our knowledge in this field.

The work of Pasteur also showed that because of the fact that yeast is a plant it requires nutritive substances of organic, nitrogenous and non-nitrogenous as well as mineral form. The chief non-nitrogenous organic nutritive substance for the yeast is found in sugar. It is usual practice to add yeast foods for the proper cultivation of the yeast.

E. C. Hansen, stimulated by the work of Pasteur, investigated the life history of individual alcohol-producing yeasts and developed the method now in use in all modern plants of procuring a pure yeast by cultivation from a single cell.

E. Buchner (1896) was the first to demonstrate that an extract could be obtained, by crushing yeast cells and subjecting them to high pressure, which would ferment sugar to alcohol and carbon dioxide as a result of the monocellular enzymes which were thus liberated.

MODERN CONCEPTION OF FERMENTATION

As now understood, the enzymes are nitrogenous compounds, either albuminoids or very closely related to albuminoids in composition, which occur in vegetable and animal organisms. Their function in the life

CONTROL FLOOR OF STILL HOUSE, SHOWING ALL CONTROL VALVES AND TAIL BOXES FLOWING ALCOHOL AT RATE OF 60,000 GAL. A DAY

processes of the organism in which they exist seems to be to transform the more insoluble food materials to a soluble form in order that they may be more readily assimilated by the organism. These enzymes may be classified into groups according to a kind of action which they exert. The proteolytic enzymes which convert protein materials into simpler bodies, such as peptones and amino acids, are of secondary importance in the production of alcohol.

There are three principal types of enzymes which convert the complex carbohydrates to simple ones: 1. The diastatic enzymes which decompose starch. The resulting products are dextrine, maltodextrine and maltose. The principal enzyme of this type is diastase (amylase), which is usually obtained from malt—that is, germinated barley. Other diastatic enzymes are obtained from the molds. 2. Maltase is an enzyme which decomposes maltose into fermentable dextrose. Maltase also occurs in malt as well as in many yeasts. 3. Invertase is the enzyme which inverts cane sugar, producing a mixture of dextrose and levulose. Invertase is found in malt as well as the yeasts.

Zymase is the enzyme produced by yeast cells which directly produce alcohol from the monosaccharoses such as dextrose and levulose. Zymase, while it produces alcohol directly from dextrose and levulose, cannot produce alcohol from sucrose or the disaccharoses nor from

DENATURING BUILDING

starch, and the other enzymes do not produce alcohol directly, but prepare the material for the action of the zymase. Thus diastase transforms starch to maltose, maltase converts this into dextrose, invertase changes cane sugar into dextrose and levulose, which are acted upon by zymase.

There are other enzymes which are not of particular interest from the alcohol production point of view.

Theoretically when sugar is converted into alcohol we should expect to obtain only alcohol and carbon dioxide. Practically, however, the fermentation is always accomplished by the formation of byproducts which decrease the amount of alcohol recovered. Yeast is an organism which consumes sugar for its nourishment and propagation, and also converts sugar into other substances besides alcohol and carbon dioxide during its metabolic changes, thus reducing the percentage conversion. The products other than alcohol formed in the fermentation are usually glycerol, succinic acid, acetic acid, butyric acid, lactic acid, propionic acid, formic acid, higher alcohols and ketones, aldehydes, with sometimes small quantities of various esters (ethyl acetate, butyrate, caproate, etc.).

Chemistry and biology have brought the process of fermentation from the point where it "just happened" and the results were sometimes one thing and sometimes another to a point where it is possible to always obtain the products desired and to eliminate to a great extent those not wanted. However, there are still great opportunities for improvement in the yields obtained and the elimination of undesirable reactions. Progress has been

made in the utilization of special ferments for the production of other alcohols and ketones and in this field of fermentation great possibilities are before us. Even in this day of much knowledge concerning fermentation we do not know exactly what the enzymes are nor just how they produce the change from starch to sugar.

POT STILL.

sugar to fermentable sugar, fermentable sugar to alcohol. We do not know just why one enzyme will produce ethyl alcohol and why another will produce butyl alcohol, glycerol or acetone. If we knew some of these things, who knows how much more we could accomplish by the process of fermentation? Wonders have been accomplished, but there still remain many fields to conquer.

A tremendous amount of work has been done and great progress has been made in working out the commercial application of the fundamentals learned concerning the process of fermentation, such as yeast growth and development of yeast, the media in which these yeasts thrive, saccharification, etc. The preparation of the raw materials has been a specialized problem and separate processes have been perfected for the handling of the different raw materials and the preliminary treatment of them which is necessary before fermentation. The process of saccharification, or the transformation of starch material into fermentable sugars, has reached a high state of perfection and all types of starchy products may be efficiently utilized.

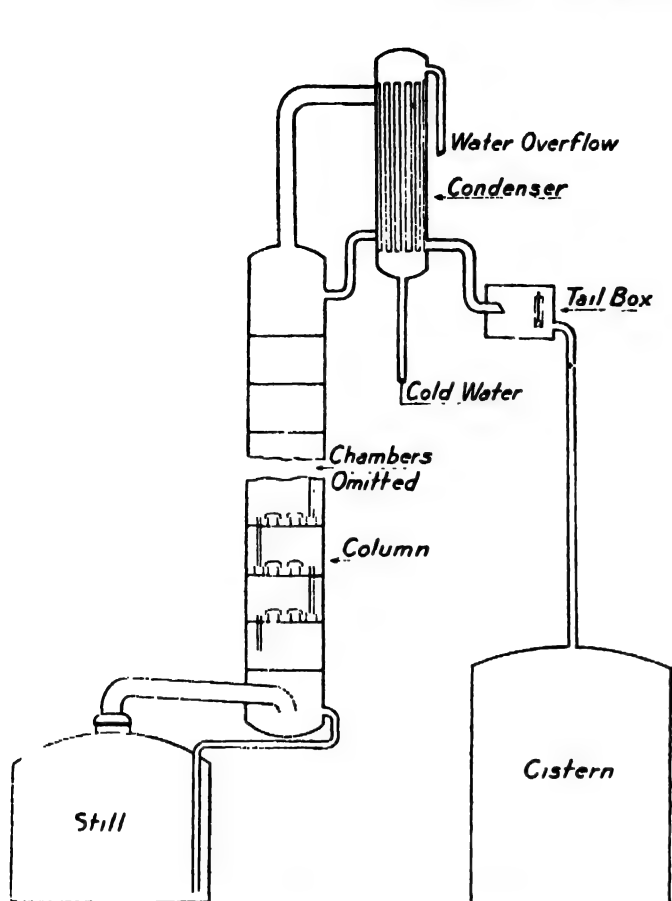

DISTILLATION AND RECTIFICATION

While the first crude stills for the production of alcohol from beverages were constructed before the beginning of the Christian era, it was not until about the

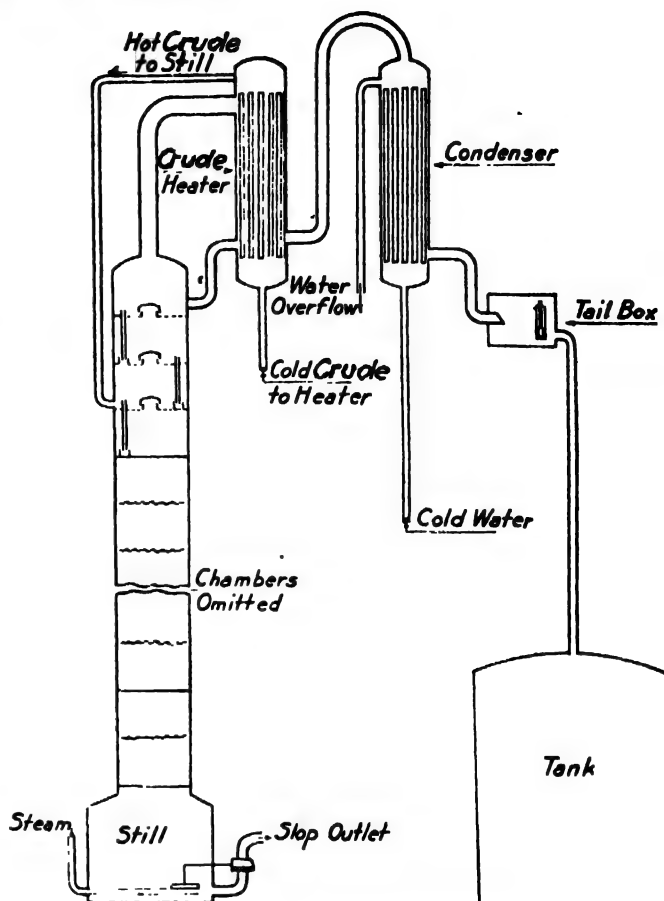

POT STILL WITH HEATER

fifteenth century that any particular progress in the construction of the apparatus was made. As the fundamentals of chemistry and physics were learned they were gradually applied to the distillation of alcohol. In the eighteenth century it had been learned that by a simple distillation concentrated alcohol could not be obtained. They knew that if they were to start with a solution containing 5 per cent alcohol the vapor would

DIAGRAM OF COFFEY'S PATENT STILL

contain over 40 per cent alcohol, but by condensing this and continuing the distillation, the concentration of the alcohol in the original solution having become less, the vapor from it also decreased greatly in alcoholic content. By redistilling the condensate they found that the alcohol content could be greatly increased. That is, if the condensate had an alcoholic content of 30 per cent the first vapors from such a solution would contain nearly 80 per cent alcohol.

The first distilling apparatus for the production of strong alcohol on an industrial scale was invented by

GUILLAUME SYSTEM DIRECT DISTILLATION AND RECTIFICATION

Edward Adam in 1801. This was a simple pot still which was heated over an open fire and which contained a heater. This heater condensed a part of the vapor from the still and the uncondensed portion of the vapors was made to bubble through the condensate before passing up to the condenser. The excess condensate was returned to the still. Progress was made gradually until 1832, when Coffey invented the still the principles of which are embodied in present-day apparatus. At the present time two general methods are utilized in the distillation of alcohol.

Many producers of industrial alcohol subject the fermented material to a preliminary distillation. This separates the alcoholic liquors from most of the yeast, water and other impurities of the fermentation. This alcohol still contains too high a percentage of aldehydes, water and higher boiling components (fusel oil) to be used commercially, so it then undergoes a secondary separation or rectification.

Some of the later types of apparatus combine the primary distillation and rectification into a continuous operation, the fermented crude entering at one point and the finished alcohol passing out at another.

The diagrams show the development of the apparatus for the production of alcohol, including the present complicated types.

Alcohol forms mixtures with water which distill at a constant temperature when the pressure is kept constant, without change of composition. At 760 mm. pressure the mixture of constant boiling point distills at 78.15 deg. C. and contains 4.43 per cent water (by weight) (Young, *Trans.*, Chem. Soc., 1902, vol. 81, p. 710). Since this temperature is lower than that of either pure component, it is impossible at ordinary pressure to obtain pure alcohol from a dilute aqueous solution by distillation and rectification only.

The grades produced as commercial products at pres-

ent contain between 94 and 96 per cent alcohol and are usually sold as they are taken from the rectifying columns. For some particular uses, however, alcohol is often purified by passing it through a filter containing carbon black or charcoal. Sometimes it is necessary to give the alcohol a chemical purification in addition to or in place of the treatment with carbon.

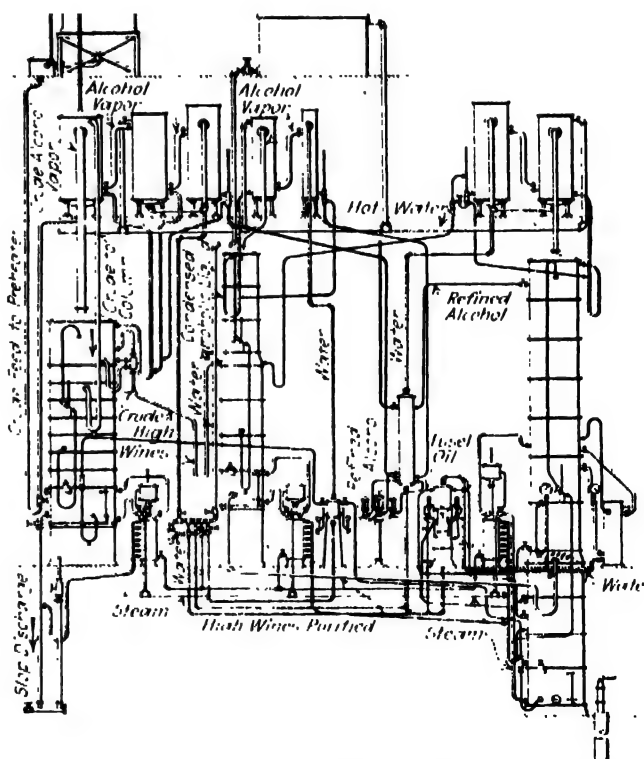

Ethyl alcohol also forms an azeotropic mixture with benzene with a boiling point of 68.25 deg. C. at normal pressure, and with water these two liquids give a ternary constant boiling mixture at a temperature of 64.85 deg. C. By a very careful study and application of the complex laws of physical chemistry concerning phase reactions, Young (*Trans.*, Chem. Soc., 1902, vol. 81, pp. 7-10) proposed a very ingenious method for dehydrating or producing absolute alcohol.

BYPRODUCTS

Scientific men have not neglected those waste materials which are incident to the production of industrial alcohol.

In alcohol fermentation carbon dioxide is formed in large quantities. Many of the modern plants have covered their fermentation tanks and are recovering this gas which finds a ready market.

Not many years ago fusel oil was considered a thing to be avoided as much as possible and that which was necessarily obtained was thrown away. Uses have been developed for this mixture of higher alcohols until today because of the demand there is considerable work being

BADGER-BARBET CONTINUOUS DISTILLATION AND RECTIFICATION SYSTEM

done toward the production of a synthetic fusel oil or the development of a ferment which will make a much greater proportion of these now very valuable products.

The fusel oil has been separated into its components by careful methods and efficient apparatus so that such products as the amyl, butyl and propyl alcohols are

obtained in a relatively pure state and are in substantial demand in the chemical and pharmaceutical industries. These alcohols as such are important solvents and are necessary raw materials for the synthesis of countless compounds.

During the primary distillation of the fermented material the crude alcohol is separated from the other components. Even today this mass of waste or "slop" in some localities is discarded. In others, however, the yeast cells are separated from the mass and are utilized in the production of plastics used in the manufacture of buttons, combs, brushes, phonograph records, etc. The slop is evaporated and the organic matter burned in some plants and the potash content recovered in the ash as a material suitable for use in fertilizer manufacture. In other cases after evaporation the organic matter is charred and the potash materials are removed by washing with dilute acid. The result is a very efficient decolorizing carbon and the removed potash salts may be purified as desired.

During the ordinary fermentation process an appreciable amount of glycerine is produced. This may be recovered.

ACCOMPLISHMENTS AND PROBLEMS

Chemistry has made the production of large quantities of practically pure alcohol an industrial reality. The application of chemistry and allied sciences to other industries has developed uses for industrial alcohol until at the present time the consumption of this necessity in the United States alone amounts to approximately 100,000,000 proof gallons per annum. Because of these sciences we have learned the composition of alcohol and its application in the production and synthesis of countless essential commodities. Chemistry has taught us the raw materials which could be used and the possible amount of alcohol which could be obtained. Biology has taken the process of fermentation and has learned its secrets and has developed fungi, determined conditions and applied these to particular raw materials so that at the present time results are obtained which were thought impossible relatively a few years ago. Engineering has rendered great assistance in the working out of the mechanical apparatus for the preparation and handling of the materials to be fermented. Chemistry has developed processes for the synthetic production of alcohol so that it may be obtained in a number of ways only a few of which at present are commercially applicable because of the relatively cheap sources of fermentable materials. The waste products in the manufacture of alcohol have been taken and made available and necessary for the production of essential commodities as previously indicated.

Chemistry, physics and physical chemistry with the assistance of engineering have improved the process of recovery and purification so that now it is possible to obtain at pleasure any grade of alcohol from 5 or 10 per cent alcoholic content, which was the best obtainable until the above sciences were applied, to absolute alcohol of the highest purity.

Of the possibilities for future development much could be said if time and space were available. There are undoubtedly a great number of raw materials available in quantity for the production of the various alcohols which have never been utilized nor their possibilities carefully studied. As economic conditions change and as the supply of petroleum products, particularly

motor fuels, diminishes the demand for alcohol will greatly increase and the available raw materials will be utilized to a far greater extent than at present.

The process of alcoholic fermentation has been developed to a high state of perfection. There are desirable results, however, which have not been obtained. In the production of ethyl alcohol, as has been indicated, the formation of other products than ethyl alcohol takes place. It would be desirable to control the fermentation a little more completely in order that only ethyl alcohol would be produced, and then if desired the other products of the usual alcoholic fermentation, such as the higher alcohols, could be produced separately.

Then there is the problem of the utilization of cellulose materials. These materials have been utilized to some extent, but it is usually necessary to prepare them for fermentation by digestion with acids under pressure.

May we not look forward to the day when a ferment will be found and developed which will make possible the direct fermentation of cellulose to alcohol on a commercial scale? That will eliminate the present necessity of hydrolyzing this material by means of acids, heat and pressure. Being thus able to produce alcohol from any material containing sugar, starch or cellulose, our alcohol may be obtained at a very low figure and our chemical industries will be assured of rapid growth and development.

There are many latent possibilities in the utilization of the slop. By proper fermentation it may be possible to obtain paying quantities of the higher organic acids. These compounds have been produced to a limited extent, but there is no general commercial utilization of these materials. This phase of the industry well warrants the time and consideration of our fermentologists.

The distillation and rectification of alcohol have been perfected until no great development is expected. The fundamental laws involved have been discovered, studied and apparatus worked out which correctly applies them. Probably the greatest development in the future will be in the matter of control. It should be possible to maintain the complicated apparatus for the distillation and rectification of alcohol under the conditions for which they were designed more continuously than is now the case.

From the alcohol made available and the byproducts of its manufacture it has been possible to place before the markets of the world a list of commodities which have done much to raise the standards of living of all countries. The application of the sciences to the alcohol and allied industries in our country has assisted in the growth of a large chemical industry in addition to making possible the manufacture of many of the primary necessities of our people. Let us hope that our chemical and allied industries may continue to expand by the application of correct scientific knowledge in order that our independence may become a greater reality.

New York City.

Fuel for Motor Transport

The Fuel Research Board of Great Britain has just issued an interim memorandum entitled "Fuel for Motor Transport." In reference to alcohol it states the production of considerable quantities of power alcohol from vegetable materials grown in the United Kingdom is not economically possible owing to insufficient acreage, high cost of production and raw materials being important foodstuffs.

The Future of the Animal Products Industry

Future Research in This Industry Will Be Centered Primarily in the Byproducts, From Which Are Manufactured: Leather; Fertilizers; Oils and Fats; Lard, Oleo Stock and Margarine; Soap; Glue and Gelatine; Organotherapeutic Products and Enzymes

• BY WILLIAM D. RICHARDSON

THE old era of the animal products industry passed away without notice and the new era began without ceremony. That era witnessed the passing of the small abattoir with its wasteful and insanitary methods and the establishment of the packinghouse on a scale adequate to handle the great livestock output of the Mississippi Valley and to vend the multifarious products and byproducts of the industry in the markets of the world. The efficiency, sanitation and commercial economy of the large establishments became proverbial. Mechanical refrigeration was generally substituted for natural. The refrigerator car came into common use and mechanical methods were highly developed and gradually extended into all departments. During this period the aim was to utilize in some way all parts of the animal body, not necessarily in the best way—the byproduct industry developed too fast for that—but at any rate in a manner which would yield profitable products.

This point marks off one period of development—everything but the bleat, squeal and moo (as the common saying is) were utilized somehow, some way, but not necessarily for the highest use or in the most economical way. The new period imposes this task on the chemist—to put all products and byproducts to the highest possible use. Nothing less is demanded and will be enforced by present economic exigencies.

The chemical laboratories under the old order were organizations with mixed functions, partly analytical, partly research and partly operative, and one chemist might be called upon to perform all sorts of work, from sampling fertilizer or tallow to operating a part of the plant. For many years routine analytical work predominated—in fact, still does predominate—and it has only been in recent years that definitely and separately organized research laboratories have been thought of.

THE MEAT BUSINESS

To the casual observer it might seem that, considered individually, carcasses of animals are handled and meats consumed by the human race today in very much the same manner as they were by neolithic man. The principal difference exhibited today is in the direction of an ever-increasing number of byproducts; then (one is reminded of the story of the apple and its core) there were no byproducts. Speaking seriously, man today eats meat when he is hungry for it and when he can get it, the best cuts taking first place, as has always been the case. Meat being a natural and desirable food, it is not likely that customs will change.

There are, however, three directions of work for the chemical investigator in connection with the general meat food industry: First, the more complete utilization of the edible portions of the animal body; second, the prevention of waste or, rather, the more complete utilization of waste parts and trimmings in the retail market

and in the home; third, more complete investigation of the dietetics of meats. So far as the further utilization of the animal carcass is concerned, it may be said that in some respects the dietitian is in advance of the public taste and in other respects public practice has gone ahead of the work of the dietitian. However, both scientific and practical dietetics and the public taste are coming closer and closer together on the subject of greater conservation of animal food products and apparently the progress is as rapid as can reasonably be expected.

The wastes and trimmings of the retailer, particularly the fats, are generally fairly well utilized, although improvements, particularly in preventing spoilage, are desirable. Wastes in the home continue and much food of value is regularly thrown out to be utilized at best in rendering works and at worst as filling material. The cure for waste of food materials in the home lies in general public education on these matters, enforced by the economic pressure of food scarcity and high prices.

In spite of the great advance made in the chemistry of foods and dietetics in recent years, our ignorance is still profound and this field will tax the efforts of our investigators to the utmost for many years to come. The chemistry of proteins and fats, their assimilation and metabolism, are realms whose borders only have been explored. Of the composition and functions of the vitamins we are still in almost complete ignorance nor, although it would be rash to predict, does it seem likely that definite information will be forthcoming in the immediate future.

THE PRESERVATION OF MEAT FOOD PRODUCTS

Of the four general methods for the preservation of foods, low temperatures, sterilization, salting processes and desiccation, all but the last are in general and extensive use in the meat-packing industry. Cold storage divides itself into two procedures: The preservation of foods above the freezing point, and their preservation in the solid frozen condition. The main principles of handling for both these methods have been carefully worked out, but there are still a number of details which will bear further investigation. The circulation of purified air in cold storage chambers, the complete regulation of humidity therein, the prevention of desiccation of frozen products and further knowledge of the chemical changes which occur in foods stored above the freezing point are among the problems requiring further attention. It is now well established that meat food products can be held in the solid frozen condition without essential deterioration for practically unlimited periods of time. When the product is not in solid frozen condition, however, certain very slow changes ensue.

Preservation by means of heat sterilization may be

said to have reached its full development some years ago and no essential changes have been introduced recently. To be sure, the machinery and the details of handling have undergone continuous evolution. The lining of tinned cans has received much attention and a greater variety of products is placed on the market each succeeding year, but the principle developed by Francois Appert in 1804 is still applied.

The great need in salting and curing processes is for more speed in the operations. Some advances have been made in the case of salted tinned meats, but for the standard kinds of cured pork hams, beef hams and bacon the old slow methods prevail limited by the speed of osmosis. While it is eminently desirable to hasten these processes, this must be done at no sacrifice of flavor or texture. In principle, the processes of today are what they have always been and improvements relate chiefly to quantity handling of product, sterilization methods to prevent spoilage and a general extension of cleanliness and sanitary methods.

Desiccation, one of the oldest methods of food preservation, is applied only to a limited extent in the meat packing industry. There is little or no public demand for dried meat products, public taste in nearly every instance preferring fresh or undried, juicy, succulent products. Before desiccation can be largely used for the preservation of meat products there must be a change in the public preference. At present drying is definitely applied only to the types of sausage of the "summer" variety, to "dried" beef, and incidentally to hams and bacon in connection with smoking. There are a number of patents in existence for drying processes, but when a manufacturing development depends on the public taste there is no certainty when or how the development will take place. There ought to be a large market for desiccated meats, but at present this market does not exist.

CHEMISTRY OF THE ANIMAL BODY

Our slowly developing knowledge of the substances and the transformations concerned in living phenomena is dependent on the general development of organic chemistry for its extension. It is dependent now upon biological tests, feeding experiments and bacteriological tests *in vitro* for information of the mere existence of many substances whose chemical nature and composi-

STEAM COIL LINED KETTLE FOR BOILING SOAP.
CAPACITY 10 TO 12 CARLOADS OF
FINISHED PRODUCT

MILLING TOILET SOAP

tion cannot even be foreshadowed at present. The immensity of this field may be emphasized by the statement that no single organ, no individual tissue, no fluid of the animal body has been investigated with any degree of completeness of results. Blood and milk have perhaps received more attention than any others, but nevertheless our information is far from complete in these cases. A more complete knowledge of the chemical nature and constitution of the substances making up the different tissues and fluids of the animal body cannot fail to make its impress on the future development of the byproducts of the animal industry. Since the bearing of this new and increased information of the general chemistry of the animal tissues cannot be determined in advance, a technologic discussion of the results at this time would be hypothetical and futile.

ORGANOTHERAPEUTIC PRODUCTS AND THE ENZYMES

What is true with respect to our general knowledge of the chemical substances composing the tissues and fluids of the body applies with special emphasis to the active principles of the secretions of the ductless glands and some other organs. The hopes for organotherapy have risen and fallen during recent years with the discovery of a new physiological action, the isolation and identification of an active principle and, on the other hand, the failure to discover, or the failure of extracts to produce, uniform results in all cases. Nevertheless, there should be no discouragement as to the future usefulness of these preparations or the importance of this branch of industry.

Passing over the great need for further knowledge of the physiological action of the active principles and extracts, one of the primary manufacturing needs is methods of standardization. Standardized products are the primary requisites. Products of good keeping qualities are also required, since standardization would be well nigh useless if the product did not maintain its original standard for a considerable period of time. Perfect standardization can be attained only with the separation and identification of the active substances. The only active principle certainly identified up to the present is that of the suprarenal gland, generally known as adrenaline, dioxy-phenyl-oxyethyl-methylamine. The problem of the precise nature of the active principle of the thyroid remains unsolved. Much work has been done on the pituitary body. Ovarian and testicular extracts

are at present somewhat out of favor with the medical profession and much physiological work remains to be done with them and the extract of the corpora lutea. The same remarks apply to the parathyroid, the thymus and the pineal gland. The nature of the digestive ferments, ptyalin, pepsin, the enzymes of the duodenum and of the pancreas remain to us as very incompletely solved chemical problems. The chemical nature of the hormones, gastrin and secretin is still unknown. In all directions a vast field lies open for the chemical investigator of these and other active principles of glands, organs and fluids. While the manufacture of organo products can never be a large part of the meat products industry, from the standpoints of chemistry, medicine and humanity this branch is of the utmost importance. A great future lies before it.

TANNING AND LEATHER

While the entire industry of animal products has suffered because it was an old industry filled with ancient customs and prejudices, leather manufacture has been stigmatized by tradition perhaps more than any other branch of it. Ancient industries which were among the arts practiced by primitive man can be put upon a modern and scientific basis only by herculean effort. New industries start from a scientific mark without the handicaps of age, tradition and rules of thumb.

Scientific progress in the art of vegetable tanning has been lamentably slow, in mineral tanning much

subject to control. At every step problems present themselves. The salting of skins and hides, including the time factor, the chemical and physical changes which occur during soaking, the changes taking place during the liming of hides, methods of deliming and the chemical and physical nature of vegetable tannage, all require much further study.

The development and use of synthetic tannins is a great problem in itself which will occupy the time of many research chemists. All along the line the substitution of definite chemicals or mixtures of chemicals and definite bacterial cultures for uncertain mixed cultures will gradually take place. It should be said that much has already been accomplished in this direction, but much more remains for future accomplishment. There are perhaps more possibilities for improvement by the chemist in the tanning industry than in any other branch of the animal byproduct industry.

FERTILIZERS

Of the fundamentals of inorganic plant nutrition we know little more than Liebig taught us. Of the specific functions of the mineral substances found in the ash of plants we know next to nothing. The fertilizer business today consists in supplying phosphates, potash salts and nitrogen compounds in suitable chemical and physical condition for application to the soil, and the farmer himself generally supplies humus in the form of barnyard manure and lime as carbonate of lime or gypsum if these are required.

The association of the animal products industry with the fertilizer trade began with the supplying of blood, tankage and bone to the latter, at first in the undried condition, later dried and ground. Gradually blood and tankage were absorbed more and more in animal foods, bones were taken over by the glue and gelatine manufacturer, so that at the present time the supply of these raw materials is steadily lessening to the vanishing point, and in the near future, if the chemist continues to keep the industry in the line of progress, none will be available for the fertilizer trade.

The fertilizer material of the immediate future will consist of phosphates from phosphate rock and basic slag, potash salts from the Stassfurt and Alsatian deposits and various salines, nitrogen compounds from natural and artificial nitrates, and ammonia compounds from the coking industry and from cyanamide. The entire fertilizer business is tending more and more toward concentrated product and herein lies the fertilizer chemist's greatest opportunities in the immediate future, since the idea of concentration carries with it the production of synthetic products and highly concentrated salts.

Concentrated phosphates are still made chiefly by the old superphosphate process depending on the separation and concentration of phosphoric acid from calcium phosphate and the acidulation of rock with the acid thus produced. Considerable work has been done on the reduction of phosphates in the electric furnace with the subsequent oxidation of phosphorus to phosphoric anhydride. Various difficulties have been encountered in the development of this process which the chemist of the future will have to overcome. At present by far the greatest bulk of phosphate entering the fertilizer trade is still in the form of ordinary acid phosphate containing approximately 16 per cent available P_2O_5 .

Although the war forced the United States to take the first steps in the manufacture of ammonia from the

OLEOMARGARINE CHURNING ROOM

more rapid. The extreme slowness of the one may be accounted for by the adherence to old formulas and methods and because the tanners have not made sufficient effort to gather around them scientists of intelligence and imagination to apply their knowledge to the old processes. Modern tanning practice is still full of salting, plumping liquors, bates, drenches, puers, pickles and tanning liquors of unknown or partly known composition and mode of action.

Fortunately—and this also is a bar to progress—in the hands of experienced masters of the art, leather of the highest quality is regularly turned out by the old methods. The things most needed in the industry may be stated briefly as increased speed and certainty of quality in the product. The speed of tanning is limited chiefly by the slowness of diffusion, but quality of product is limited by the uncertain composition of preparatory fluids and tan liquors, both of which are

nitrogen of the air by the direct process as well as the indirect, this manufacture is not yet established. Ammonium salts still have their source in the coke industry and nitrates in the salt mixtures of Chile. The price of fertilizer nitrogen is higher at present than it has ever been and there appears to be a considerable shortage of nitrogenous materials. Nevertheless, there is still a question about the commercial practicability and success of some of the fixation processes unless practiced on a very large scale with cheap power. Considerable experimental work has been accomplished in connection with fixation by means of nitrides, but the development of these processes also lies in the future. Cyanamide, however, is firmly established in the fertilizer industry, as are also ammonium salts derived therefrom.

The American potash industry starting up at various points chiefly in the Western United States and working on different sources of raw materials suffered a setback when the armistice was signed, but later, when potash imports did not reach the expected tonnage, took a new lease of life. Some of the plants, particularly those manufacturing from the Nebraska lakes, have been in the main successful throughout. Others, such as those working on the mother liquor from salt crystallization at Great Salt Lake and Saldura, Utah, achieved partial success. The kelp potash plants were successful during the war and the Searles Lake industry, having encountered many difficulties, according to reports can now turn out potash salts containing less than 0.5 per cent borax. There is a grave question about the success of any of these enterprises in competition with foreign potash salts when these are received at our ports in the quantities demanded by our industries, but it is hoped that since the industry has been established here it will continue.

There is one thought which should be taken to heart by American chemists generally in connection with this situation and that is whether any other great country of the world would fail to utilize to the best advantage as a source of potash and organic chemicals the great kelp beds of the Pacific Coast. The Department of Agriculture has given encouragement to the development of the kelp potash industry and still maintains the experimental plant at Summerland, Cal. That the industry will be well established some day seems certain, but it is unfortunate that it went out of existence, practically speaking, with the signing of the armistice.

OILS AND FATS

Twenty years ago the oil and fat chemist labored under the impression that his knowledge of oils and fats was in the main sufficiently complete and satisfactory. Today he realizes that he is only beginning to obtain information of these most important substances—important alike to manufacture and technology, dietetics and physiology. After Chevreul showed that animal and vegetable fats could be hydrolyzed into glycerol and fatty acids, the principal effort of chemists and technologists, resting on this information, was to utilize these two products in the best way for the manufacture of soap, candles and refined glycerine. In dietetics fats were considered as so much fuel, in physiology as substances which were stored up in the body to be consumed as fuel in time of need. The great functional importance of fats physiologically has come to be appreciated only within the past few years.

The proximate composition of the fatty acid complex

of several of the fats has been worked out, but even this work is very far from complete. When the composition of any of the well-known fats themselves in terms of their glycerides is considered we realize at once our almost total ignorance. We do not know the composition completely even of the fatty acids of the common fats, and we have only the slightest information in regard to their mixed glycerides, and most of this is hypothetical. The isomers of oleic, linolic, linolenic and clupanodonic acids, the chemical changes taking place in rancidity and other little understood oxidation processes, and in the drying of oils, all require much more work for their elucidation. The mechanism and reactions of digestion and assimilation of fats and of their synthesis in the body remain unsolved. Of the real basis of the shortening power of fats and oils our knowledge is negligible. Opinions vary as widely as the results of tests thus far conducted and theory on the subject is chaotic. On the technological side there is still a waste of fats and loss of quality at various points which can and will be overcome. Rendering and extrac-

OLEOMARGARINE ROTARY WORKERS FOR WORKING IN
THE SALT AND SQUEEZING OUT THE
EXCESS MOISTURE

tion processes are both susceptible of improvement. Refining processes also are incompletely developed and considerable betterments may be looked for in the future.

Since color, bad flavor and high free acid are generally associated with one another, improvements which improve one generally improve the others. Prompt handling, low temperatures and the avoidance of the use of strong chemicals, so far as this is possible, should be the rules in the handling of fats. It is becoming more apparent that excessively high temperatures which have been used in refining processes may not be desirable from several standpoints. We may hope to see in the not far distant future a better correlation of our knowledge of fat constitution and physiological function with production and refining processes.

LARD, OLEO STOCK AND MARGARINE

The chemical and mechanical features of lard manufacture have been very well worked out and do not require the immediate attention of the chemical technologist as much as other departments of the fat and oil industry. On the other hand, while the rendering of

oleo fats is handled in a satisfactory manner, the methods in vogue for seeding and pressing the stock are primitive. Mechanical seeding apparatus has been introduced at a few points and attempts have been made to improve and simplify the presses. It is likely that within a few years mechanical seeders will be universally used and that a suitable press will be developed capable of displacing the present clumsy and laborious pressing methods. Like all the old processes, however, those at present used for the manufacture of oleo oil and stearine produce excellent products, and this fact is as usual a bar to progress.

Legislation, tradition, custom and the public taste have all been factors in retarding the development of the oleomargarine industry. Legislation has always favored the butter industry and favors it at the present time. Following tradition and custom, oleomargarine manufacture adopted many of the methods used for handling butter, whereas it is altogether likely that simpler manufacturing processes could be devised which would make a perfectly satisfactory product. On account of adverse legislation which permits butter to be colored and denies or penalizes the privilege in the case of margarine, manufacturers are inclined to sacrifice flavor to color and unfortunately public taste commends this policy. Legislation should not be partisan in this respect. If color is used in the one case it should be used in the other or the privilege of coloring should be denied both industries.

In recent years there has been a great increase in the variety of oils used in margarines. Formerly oleo oil, cottonseed oil and neutral lard were the three chiefly used. At the present time the list has been extended to include coconut oil, peanut oil, soya bean oil, hydrogenized product and others. Many so-called nut butters composed largely or exclusively of coconut oil have been placed on the market, and while these have not proved the equal of standard oleomargarines in point of flavor, keeping quality or melting point range, they have met with much public favor.

The oleomargarine industry is steadily increasing, although the consumption in the United States is still behind that of most European countries. Indeed, our consumption of butter and butter substitutes taken together is below that of many foreign countries. The future development of the oleomargarine business will probably lie in the direction of an increasing list of raw materials, improved emulsification, and simplification of the mechanical processes used, with a general tendency away from the methods used in the manufacture of butter, thus allowing the industry better opportunity to work out methods specifically adapted to its own needs.

HYDROGENATION

While hydrogenation, or the conversion of unsaturated into saturated fats by addition of hydrogen, has been well accomplished, the reverse process, dehydrogenation, remains unmastered, nor is there available at present any chemical information capable of foretelling how or when this development may be achieved. Hydrogenation has been brought to a meritorious first development, and the industry, satisfied for the present, does not appear to be undergoing any marked technological developments. Aside from more active and cheaper catalysts, which are always in demand, some of the desiderata are methods for purifying low-grade oils so as to fit them for hydrogenation and render them incapable of killing

the catalyzer before the reaction is completed, a method for the manufacture of cheap, pure hydrogen other than the electrolytic way, and methods for purifying hydrogen as produced by the steam-iron process. However, for one so recently developed the industry is in a very healthy, thriving condition.

SOAP

The soap industry also has come into the modern era following a long train of ancient methods and customs. On the manufacturing side two broad improvements are needed: first, greater speed in the saponification and boiling processes, and secondly, quick mechanical methods of molding the liquid product into bars. Even though the first reform may be long delayed on account of the necessity for separating glycerine lyes, there can be no valid excuse for greater delay in instituting the second procedure. The tedious processes of framing,

CONG JALING REFINED LARD ON REVOLVING TANDEM ROLLERS

chilling, slabbing, cutting and pressing ought all to be condensed into one continuous operation. This is the next important practical step in the industry.

This is not the place to dwell on ethical reforms in industry, but it would seem from every standpoint that the soap industry would do well to rid itself of the gross adulterations practiced therein and return to the manufacture of purer soaps. All fillers and adulterants added to soaps, without exception, lessen the detergent power, having none in themselves or much less than the soap to which they are added. Sodium resinate and sodium silicate may be excused on the grounds of easier solubility when used in small proportion. They can hardly be excused when used in extreme quantities. Other fillers, such as mineral fillers, petroleum oils and the recently advocated clay, can scarcely be justified on any grounds except that one manufacturer begins it and the others follow suit to meet competition. There is no substitute

which is the equivalent of pure soap in detergent value. The manufacture of soap based on detergent value has not been undertaken. Some attention has been given to solubility (particularly in the case of textile soaps) and also to lathering qualities in the case of ordinary toilet and laundry soaps, but for the most part soap manufactures and soap products rest upon an empirical foundation or worse. Special forms of soap to catch the public eye and preference have been introduced without number and unwarranted claims are frequently made for them in extravagantly worded advertisements so that on the whole the public is uninformed or misinformed as to what constitutes good soap and buys largely on the basis of whim and prejudice—not a good foundation for the marketing of any standard commodity. Usually and perhaps always it is the advertising or the premium rather than the quality and the price which sells the soap. The public needs reforming as much as or more than the manufacturer.

GLUE AND GELATINE

On both the chemical and physical sides collagen and gelatine offer an unlimited field for the investigator in pure science. The problems connected with these substances are innumerable. Their chemical composition so far as it has been unraveled differs as greatly as their physical properties from the other animal and vegetable proteins and even from elastin. A more complete understanding of these substances must await the time when our chemical knowledge of the entire protein group is more fully developed.

The industry has developed empirically and the rules of thumb have been handed down from workman to workman, generation to generation. Many attempts have been made to quicken the liming process by the use of caustic soda and with considerable success. Open cooking with circulating water has come into partial use only. Clarification by means of centrifugals has displaced filtration methods to some extent. The greatest improvement has come in the mechanical handling of jellies by means of the belt-chilling system, which has displaced the old jelly pans all but universally. Much attention has been given to improvements in drying methods, but trouble is still experienced in most tunnel systems during warm, humid weather.

The slow evolution of byproducts manufacture in the animal industry is well illustrated in the handling of bones. At first these, together with other raw materials of the fertilizer industry, were sold at a low price to neighbor firms which worked up the byproducts of the packinghouses, at that time concerned primarily with dressed live stock and cured meats. Next the bones, after first being boiled in open vats for tallow or oil, were dried and ground into raw bone meal and sold for fertilizer.

It was considered a great step in advance when the same bones were steamed for glue and the dried residues sold for fertilizer as "steam bone meal." This product, following the conservation movement of the day, was later worked into animal and chicken feeds. Today some of the large establishments are just beginning to realize that bones are capable of yielding still higher values as gelatine stock. The foregoing refers to ordinary bones. The stronger and heavier bones have always been worked into knife handles, buttons and other objects.

There is much room for improvement in the matter of standards for glue and the methods of arriving at these standards. Although some attempts have been made to

put glue testing on a scientific basis, little headway has been made and reference is still had to arbitrary standards. The viscosity determination has been improved and may be said to be on a reasonably satisfactory basis at the present time. On the other hand, the determination of jelly strength is not on a satisfactory basis and there is no agreement among manufacturers and users as to the method to be used. Several types of mechanical devices are installed in different glue laboratories and in others the antiquated, uncertain finger test is still supreme. Its advocates claim that it is more certain and reliable in the hands of an expert than any mechanical device, which is far from the truth. Reform in these matters must come in the future by general agreement among manufacturers and users.

RESEARCH

The greatest need of the animal products industry today is the establishment of large, thoroughly organized and well-equipped modern research laboratories. They should be entirely separated from the usual routine analytical laboratories and should have on their staffs the best available experts in the various branches. Without these, progress in the new sense cannot be made and the industry will move ahead by inches where it should go forward by miles. Fortunately, the progressive heads of the large establishments are seeing this need and it may be confidently hoped that in the very near future research in the best sense will be in the hands of an adequate personnel and backed by ample funds. It is hardly necessary to state that research will be applied in the main to the byproducts of the industry. The principal branches of the business are already on an eminently satisfactory and efficient basis.

Changes in the American Diet

Whether it is because of the increased cost of meat or because people's tastes have changed, the fact remains that Americans are eating 8 per cent less meat than they were twenty years ago. This is disclosed in a recent dietary survey made by the United States Department of Agriculture. In this survey 2,000 dietary records, each covering a period of seven days, were collected from 1,425 families and 575 institutions in forty-six states. Sixteen nationalities and many occupations and incomes were represented, as were also both urban and rural localities.

From a summary of 500 of these family records it appears that last year the average cost of food per man per day was 46c., with an average return in food value of 3,225 calories, 96 grams protein, 118 grams fat and 405 grams carbohydrate. These figures are in fairly close accord with the dietary standards ordinarily used in discussing such problems of general nutrition.

A comparison of the foodstuffs purchased by the 500 families with the amounts of the same food purchased by 400 families about twenty years ago shows that the amount of meat in the American diet has decreased about 8 per cent and the amount of grain products about 11 per cent. People are eating more milk, butter and cheese than they were two decades ago, for the amount of dairy products consumed has increased about 6 per cent. Four per cent more vegetables and 8 per cent more fruit are being eaten now.

Some individual food habits undoubtedly need to be corrected, but, judging by these studies, it seems fair to conclude that the average diet seems to be adequate. (*Pure Products*, vol. 16, No. 6, 1920, p. 308.)

Artificial Leather and Coated Fabrics

A Succinct Review of the Development of the Artificial Leather and Coated Fabrics Industries and of the More Important Steps Involved in the Manufacturing Processes Employed, With Special Reference to the Use of Pyroxylin Solution Coatings

ARTIFICIAL leather is a loose term more generally applied to any composite material made up of a base such as cloth, felt or paper, upon which is spread a coating embossed in imitation of grain leather. A very satisfactory product was obtained by coating split leather with pyroxylin. This led to the substitution of fabric for the leather, and thus began a large and growing industry. Stevens first suggested the use of amyl acetate as a solvent for pyroxylin, creating the pyroxylin lacquer industry; in 1884 Wilson and Story first coated cloth with a pyroxylin-amyl acetate solution with which was combined castor oil, the forerunner of the formulas in use today in the manufacture of artificial leather. Subsequent improvement in the latter product has been dependent upon the development of more satisfactory and cheaper solvent formulas, mostly discovered by rule-of-thumb experiment, and also through the use of a better quality of nitrocellulose.

As the result of improved methods for the purification and the nitration of cellulose, a product is obtained which, when combined with a suitable solvent, produces a "dope" which can be readily applied to the base and upon evaporation of the solvent becomes a tough, elastic and durable film.

THE BASE MATERIAL

Little if any change has been made in the base material; the ordinary weaves of cotton cloth have not been improved upon. Cotton cloths, such as sheetings, ducks, sateens and the heavier mole-skins, do not possess an equal stretch in all directions. The strength of the coated fabric on the bias of the weave is somewhat dependent upon the toughness of the film, and in the present state of the art toughness of the film is, unfortunately, gained at the expense of pliability. Even should an improved film be developed, the unequal stretch of the base fabric would remain; a more suitable base fabric would, therefore, considerably improve the quality of the product. For many uses the unequal stretch of the fabric is immaterial; for certain uses the base may be composed of paper, felt or other substance.

For automobile tops the coating is more often composed of rubber, or rubber substitute, or of boiled linseed or other oil combined with pigments. These are not usually termed by the trade as an artificial leather; they constitute, however, a very large class of coated fabrics.

The factors that control the physical and the chemical characteristics of nitrated cellulose are sufficiently well understood, and it is possible to obtain a product which is fairly satisfactory. Nevertheless certain qualities of the pyroxylin are still largely dependent upon the source from which the cellulose is obtained; the fibers from the seeds and the hulls of cotton are considered the most satisfactory. It is possible to purify and to nitrate wood pulp or other cellulose substance, but it is difficult to obtain uniformity of product. At the pres-

ent price of wood pulp, cotton linters and hull shavings it is a question whether any real economy would result from the substitution of wood pulp. Uniformity of product is essential. A fairly complete dehydration of the nitrocellulose is also essential, and it is therefore necessary that the nitrocellulose be insoluble in ethyl alcohol, as in the most satisfactory method of dehydration the water is displaced by alcohol.

MANUFACTURE OF PYROXYLIN-COATED FABRICS

The manufacture of pyroxylin-coated fabrics is not a complicated process. The more important steps are: Solution of the nitrocellulose in a solvent; incorporating oil and pigment with this solution; spreading the mixture on the fabric or other base material; evaporation of the solvent; recovery of the solvent (this step is not essential); embossing the coated fabric.

Cotton cloth is generally used as a base. This must be free from imperfections of weave and must be made from uniform yarn, as loose or heavy threads will show in the finished product. Light-weight fabrics, such as sheetings, are usually sized; heavy-weight fabrics are teased to raise the nap. The cloth is usually dyed in order to prevent any discoloration of the back becoming apparent should the coating come through the cloth. In the light-weight fabrics this is largely prevented by the sizing, the primary object of which is to stiffen and weight the goods. Raising the nap on the heavier weaves assists in producing a firm anchorage of the coating to the cloth. For certain uses, such as wall coverings, paper may be used as a base; felt, or fabric made from other material than cotton, may be coated successfully.

SOLVENT FORMULAS SECRET

Many solvents and combinations of solvents have been used; it is to the development of improved or less expensive solvent formulas that the expansion of the industry has been largely due. For this reason the manufacturers of artificial leather keep their formulas secret. Patent literature is replete with solvent and "dope" formulas, but it is quite certain from commercial considerations that but few solvents are being used. The manufacture of artificial leather is a highly competitive business; for this reason the solvents selected are restricted to those that can be obtained cheaply. Ethyl alcohol is relied upon in the dehydration of the nitrocellulose and is an incidental constituent of most solvent formulas, but other aliphatic alcohols could be used. On the other hand, alcohol is not an essential constituent. Amyl acetate is now largely replaced by the cheaper ethyl acetate; this is diluted with benzol or other hydrocarbon of the benzol series. Benzene or gasoline is a constituent of some formulas. The pyroxylin solution must be clear, free from dirt and undissolved nitrocellulose, and as near as possible of a standard viscosity. The solution will contain from 75 to 90 per

cent solvent. If such a solution were used to produce a heavy film, the finished product would be stiff. In order to obtain pliability an oil is mixed with the pyroxylin solution, and to this mixture may be added pigments ground in oil to produce a colored coating.

OILS USED TO GIVE PLIABILITY

Various oils may be used to give pliability to the film. Castor oil was first used, and no satisfactory substitute has been found where a light-colored coating is required. This oil has, however, an objectionable odor which is noticeable in the finished product. Other oil may be substituted for castor, such as blown linseed, rapeseed or cottonseed, or a mixture of these; and other non-drying or semi-drying oils have been used. Blown oils are dark in color and therefore cannot be used with the lighter colored pigments. Another source of trouble is the likelihood of the commonly used oils becoming rancid if the finished product is stored for any considerable time. A cheap, non-drying oil that is light in color and one that would not develop rancidity would fill a long-felt want in the industry. Standard pigments ground in oil are used to give color to the coating. The less expensive pigments are chosen. Except for light-weight coatings over a non-dyed base material it is not necessary that the pigment possess great covering power.

THE COATING

The coating on a piece of artificial leather is built up of a number of thin coats, all of which do not have the same composition. Upon light-weight fabrics as few as three coats may be applied, while to produce an imitation of heavy Spanish leather, such as is used for upholstery, twenty-five to thirty or even more coats may be necessary. The first two coats are depended upon to give anchorage; these are of special composition and usually contain less oil and pigment than the succeeding coats. The top coats give the finish to the product, and take all the wear. These are applied thinly, except on very light-weight goods; usually the top contains neither oil nor pigment. Exceptions would be the imitation Spanish and Morocco leathers, to which are applied an elaborate hand finish; or, in cheaper grades, machine finish.

Individual coats are applied, drawing the base material under a knife-edge, the "dope" being run onto the material in front of the knife-edge as fast as it is used. This operation is performed by machines. By paying attention to such details as the design of the knife-edge, the tension applied to the base material and the viscosity of the pyroxylin solution, it is possible to control the weight of each coat. In the present state of the art the quality of the product is improved by increasing the number of coats for a given weight of coating. This adds to the cost of production. Here is a very promising field for development. Considerable ingenuity and a large amount of capital have been expended in attempting to solve the problem, so far without marked success.

Between individual coats the solvent is evaporated from the film more or less completely. Often some solvent is retained in the finished piece to give additional pliability, and a high boiling point solvent may be added for this purpose. This is not, however, a satisfactory method of obtaining pliability; in the first place, it is more expensive than other methods that may be used; in the second place, such solvent ultimately evaporates from the coating and thus defeats the purpose for

which it was added. If an attempt be made to recover the solvent, that added for this purpose is an unnecessary loss.

RECOVERY OF SOLVENT A SUBJECT FOR DEVELOPMENT

It is still a moot question as to whether the solvent which must be evaporated from the coating should be recovered or not, the claim being made that a better quality product can be produced without solvent recovery. For theoretical reasons the reverse should be true. With a properly designed recovery apparatus it is possible to control drying conditions and in this way produce a more uniform film. If from 80 to 90 per cent of the solvent can be recovered, there is no question that recovery is economical. With the probability of increasing prices for solvents, the manufacturer with efficient solvent recovery apparatus has a decided advantage, both as to costs and quality. The problem of putting the recovered solvent into suitable condition for re-use is not difficult. There is an opportunity for considerable development along these lines.

EMBOSSING TO IMITATE GRAIN LEATHER

The coated material from which all or at least a large proportion of the solvent has been removed is embossed in plate or rotary presses to get an imitation of grain leather. The heavier grades are preferably embossed on plate presses, as these are likely to roll-cut, and deep embossing is to be avoided. Imitation Spanish and Morocco leathers are hand-finished to give the impression of age to the product. To obtain this appearance a light deposit of a pigment darker in color than the coating is spread over the embossed piece of goods. This pigment is rubbed off of the high spots into the valleys of the embossing by means of a pad soaked in a solvent that softens the film slightly, anchoring the pigment onto the coating.

TWO PROBLEMS AWAITING SOLUTION

Two problems of utmost importance in the artificial leather industry are awaiting satisfactory solution. The first is the production of a durable film with fewer number of coats and the second has to do with the recovery of solvents. These apply to pyroxylin-coated fabrics. As has been pointed out, the base fabrics in use are not as satisfactory as could be desired. It is quite probable that the market for coated materials can be further developed, with improvement in durability and reduction in costs.

Recent Patents on Artificial Leather

Among the quite recent patents on the manufacture of artificial leather may be mentioned the United States patent No. 1,337,802 and the German patent No. 302,445.

The American patent, by Albert E. Somerville, consists in winding into a roll a vulcanizable rubber layer and sheet of paper in intimate surface contact with each other, subjecting this roll to the action of the vulcanizing medium, and removing the paper sheet, thereby providing a material having the characteristics of dull finished leather.

The German patent, by E. Reidel, consists of treating dried animal intestines, sinews and the like with acetic acid or sodium sulphide. The product is washed, compressed between rollers, dried and saturated with a solution of albumin and a marine animal oil. The product, after compression to sheets, is dried and tanned by the combined mineral and vegetable process.

A VIEW IN THE DEBEQUE, COLO., OIL SHALE REGION

The Necessity for Research in the Oil-Shale Industry

An Account of the Shale-Oil Industry as Developed in Scotland—Steam-Regulated Pyrolytic Distillation—Quality and Quantity of Oil Yields—New and Improved Practice Should Be Developed From Old Operation

By MARTIN J. GAVIN*

ONE rarely reads a technical or oil-trade journal without coming across some article or statement regarding oil shale. We are told of the enormous supplies of this material within the borders of the United States, of the plants to treat shale that are operating or under construction or about to be constructed, of the companies organized to produce and refine oil and other products from oil shale, and commonly of the huge profits to be made on small investments in oil-shale operations. Supplementing these articles, the country has been well covered with oil-shale company promotion literature, commonly of a still more optimistic and often misleading nature. The public apparently has been led to believe that the American oil-shale industry is a going one—that is, plants are making and refining shale oil on a successful commercial scale—and that money is actually being made in oil-shale operations by marketing shale oil and its products.

SHALE-OIL INDUSTRY ACTIVITY

The writer does not desire to discourage the proper kind of activity in connection with oil shale, because the time is growing near when shale-oil products will undoubtedly be necessary to supplant in part our present petroleum supplies, and he believes that in the course of a comparatively short time oil-shale operations, if properly conducted and financed, can be made commercially successful. It is desired in this paper to indicate particularly the great necessity of properly conducted scientific research and control work on oil shale and shale oils, without which it would be indeed difficult to carry on oil-shale operations successfully.

At the present time there are, strictly speaking, no commercial oil-shale operations under way in the United States. There have been perhaps eighteen or twenty shale retorts erected in the country and most are in

intermittent operation from time to time for experimental or demonstration purposes, but with one or two possible exceptions these are too small to give much of an idea of their commercial feasibility. Nearly if not quite 150 companies have been organized in connection with oil shale, many of which, unfortunately, are purely stock promotion concerns. Some are actually engaged in experimental work of a sort, and a very few are actually conducting well-planned and organized investigational and research work.

GREATER CO-OPERATION AMONG INVESTIGATORS NEEDED

There is very seldom a laboratory at the experimental plants, and only infrequently a well-trained technical employee. Except in a very few cases, shale oils produced in the small plants have never been given more than very superficial inspection and the real quality of the oil made is generally unknown even to the operators themselves. There is little spirit of co-operation among the oil-shale operators, each apparently believing his idea of a shale retort to be far superior to all others. In passing, the writer expresses as his opinion that mutual helpfulness and co-operation will go a long way in the building of a successful oil-shale industry in this country, as there is so much work to be done and so many problems to be solved that no one individual or company can hope to do it all.

NOT ENOUGH CONTINUOUS EXPERIMENTAL WORK

Experimental work in connection with oil shale, again, with one or two notable exceptions, has so far consisted in the construction of a retort, usually designed along lines as different as possible from the well-known Scotch type of retort, and its operation at maximum capacity until a certain lot is run through; then it is shut down until another lot is ready for testing.

Rarely is attention paid to the quality of oil produced. As far as the writer knows, none of the plants has been operated long enough or under such conditions as would

Printed by permission of the Director, United States Bureau of Mines.
*Refinery Engineer, United States Bureau of Mines.

give an idea of its life in commercial practice. A run is usually considered successful if oil is produced and the residual shale yields practically no more oil. There are practically no recognized retorting methods and usually, in any particular type of retort, all shales are treated under the same more or less accidental conditions.

As a rule the retorts are designed with the idea of removing oil vapors from the retort as soon as they are formed, but this idea is not always carried out. Most retorts builders try to get as far away from Scotch practice as possible and though many use steam in retorting, the quantity used is so small or it is applied under such conditions that it gives negligible results.

THE SCOTCH PRACTICE

For a proper understanding of problems in shale-oil production and refining, it is desirable that Scotch practice in this regard be outlined, as it is generally not well known, or its principles are misinterpreted.

In the following discussion the writer wishes it to be understood that he does not believe Scotch oil-shale retorts and operations to be the last word in the oil-shale industry. It is reasonable to believe that types of retorts and practices different from those employed in Scotland may be developed in this country more particularly adapted to American shales and conditions. It is emphasized, however, that the Scotch oil-shale industry is really the only commercially successful oil-shale industry in the world at the present time and that it has been successful for more than sixty years. This being the case, the logical first step in the development of an oil-shale industry in the United States, a new art here, would be an attempt to apply the apparatus and practices now used in the country where oil-shale operators have reached their highest development. If Scotch methods are not found satisfactory in this country, it may be possible to modify them, and even if modifications are unsuccessful, the knowledge of Scotch shale operators, based on over sixty years of practical experience, cannot reasonably be disregarded but logically should serve as points of reference.

In Scotland the shale brought from the mine is crushed by toothed rolls into pieces of average size of an ordinary brick; as a rule everything going through the rolls goes to the retort.

SCOTCH RETORTS

From the breakers the shale is carried in cars up an incline to the top of the retorts, where it is dumped into the retort hoppers by hand. The most commonly used Scotch retorts are vertical and tapered, consisting of the following parts: At the top there is a hopper, which holds several hours supply of shale. Below the hopper is a cast-iron upper part which is about 12 ft. in length and which has a vapor outlet near the top. Under the cast-iron part, and joined to it with a fire-clay joint, is the lower masonry part, which is about 18 ft. high and made of a single tier of very special-shaped firebrick. At the bottom of this part is the discharge mechanism and below that the spent-shale hopper, which serves one or two retorts and in which the spent shale accumulates. The cast-iron part is made circular or elliptical in cross-section, and the masonry part square or circular. Those of circular cross-section have an internal diameter of about 2 ft. at the top and 3 ft. at the bottom. The taper is constant.

Each retort, with its supply hopper, holds about nine tons of shale and the feed is by gravity. Four retorts, as described, are set in a common furnace and are heated by the combustion of the fixed gases resulting from the distillation of the shale, supplemented by coal producer gas when necessary. Four retorts are a unit, and sixteen such units constitute a bench, two retorts wide and thirty-two retorts long. The present retort working on shale now being mined in Scotland has a capacity of about four and one-half short tons per day. Tests indicate that the retort capacity is a function of oil production rather than shale throughput. Apparently a Scotch retort will produce approximately 100 gal. of oil a day, whether it is working on a 10-gal. shale or 100-gal. shale. In the former case approximately ten tons can be put through; in the latter but one.

In the upper or cast-iron part of the retort most of the oil distills and the maximum temperature in this part does not exceed 900 deg. F. The lower or masonry part serves mainly as an ammonia and gas producer. About 105 gal. of water, as exhaust steam, for each 25 gal. of oil produced is admitted into the spent-shale hopper and passes up through the shale in the retort. The steam serves to absorb the heat from the spent shale, to produce water gas from the fixed carbon remaining in the spent shale, to distribute evenly the heat in the retort, to produce ammonia from the nitrogen of the shale, and to carry off the oil products formed. Distillation with steam increases the yield of ammonia about two and one-half times as compared with dry distillation, and also produces more oil which is of higher quality.

TEMPERATURE AND HEATS

The maximum temperature to which the shale is subjected is not much in excess of 1,500 deg. F., although temperature measurements have never been accurately made within the retort itself. The retort operators are skilled in judging retort temperatures by heat colors, and keep temperatures under careful control by looking into the furnace through peepholes. In general, in retorting and refining practice in Scotland, one is struck with the very definite way conditions are controlled. Many years of practical experience have determined these conditions.

The spent shale is discharged continuously from the retorts and the mechanisms used for this purpose constitute the main points of difference between the types of retorts. The spent shale is refuse. No commercial use has ever been found for it, although it has been tried in road and brick making. The fixed carbon remaining in the shale amounts to only $1\frac{1}{2}$ to 2 per cent. This is the economic limit with reference to fuel consumption, throughput of shale, and ammonia and gas yield. A greater yield of ammonia could be obtained by reducing the amount of carbon, but at the expense of throughput.

VAPORS SEPARATED FROM GASES AND REFINED

Vapors pass out of the retort through the vapor line, which is cast integral with the upper part of the retort. Large suction fans in the dry gas main, between the scrubbers and gas burners, put a slight suction on the retorts. The vapors pass to large headers and thence to a series of U-shaped, vertical, air-cooled condensers made of cast-iron pipe. Below each U is a

receiving box for condensate, and from this box the condensed oil and ammonia water are drawn off to separating tanks. Uncondensed gases pass through water scrubbers, which remove any ammonia remaining in the permanent gases, and through oil scrubbers, which remove the light hydrocarbons, commonly known as "scrubber naphtha." The gas is then led back to the retort furnaces, where it is burned.

Shale now being worked in Scotland yields per short ton approximately 10,000 cu.ft. of gas having a heat value of about 240 B.t.u. per 1,000 cu.ft., approximately 24.5 U. S. gal. of crude oil and 36 lb. of ammonium sulphate.

The crude oil, after having the bulk of the water separated, is run to the refinery. The refining of this oil is more involved and complicated than the refining of petroleum, as the oil must be subjected to more acid and alkali treatments and a greater number of distillations. Therefore a shale-oil refinery contains more small stills and agitators than does a petroleum refinery of equal capacity. More batch stills are used than continuous stills, and the Scotch shale-oil refineries have extraordinarily large wax plants compared with petroleum refineries of equal capacity.

FLOW SHEET OF PRODUCTS AND PLANT LAYOUT

Practically all refinery distillations are conducted with a large quantity of steam, which is admitted into the bottoms of the stills. The crude oil is run to coke, as are also some of the redistilled oils.

The yield of refined products in Scotland is somewhat as follows:

	P ₁
Naphtha (including scrubber naphtha) 450 deg. end point	9.9
Burning oils (kerosene and like) . .	21.7
Gas and fuel oils	24.4
Lubricating oils	6.7
Wax	9.5
Still coke	2.0
Loss	22.8
	<hr/> 100.0

A general idea of the complexity of shale-oil refining in Scotland can be gained by referring to Fig. 1, a generalized flow sheet of refinery operations at a typical Scotch shale works. This figure and Fig. 3 are presented through the courtesy of Scottish Oils, Ltd. The writer wishes to express his appreciation particularly to H. R. J. Conacher of this organization for the use of these figures.

Scrubber naphtha, which is the gasoline or naphtha recovered from the retort gases by washing them with oil and subsequently distilling the latter, amounts roughly to 2.4 gal. per ton of shale.

Ammonia water from condensers and scrubbers is run to ordinary continuous ammonia stills. Ammonia gases pass off and are dissolved in dilute sulphuric acid, much of which is recovered from the acid tars. The sulphate solution is concentrated by a continuous system and is finally purified and sold as crystalline ammonium sulphate.

Fig. 2 is a plan of a typical modern Scotch oil-shale works, including retorting plant, oil refinery and ammonium sulphate plant, with accessories. It serves to indicate the outlay and equipment necessary in the production and marketing of refined oil-shale products, and gives an idea of the scale under which Scotch operations are carried on. Such a plant represents the investment of several millions of dollars.

The principal objection in the minds of American shale operators to the Scotch retort is its low through-

put and its use of steam. Scotch operators find that it is necessary to heat their shale slowly and to use plenty of steam if a satisfactory oil is to be produced, and the past tendency in Scotch practice has been to lengthen the time of treatment and use more and more steam. As a matter of fact, the amount of steam used is largely determined by the amount of oil a shale will yield. Rapid production of oil from Scotch shale has meant that an oil of poor quality resulted, though not enough work has been done on American shales to determine if they will behave the same way.

The use of steam in retorting apparently does so much more than merely produce ammonia that its use cannot be abandoned without further consideration even if ammonia recovery is not desired. The spent shale coming from the Scotch retorts is very hot (perhaps 1,500 deg. F.) and if not steamed would be discharged

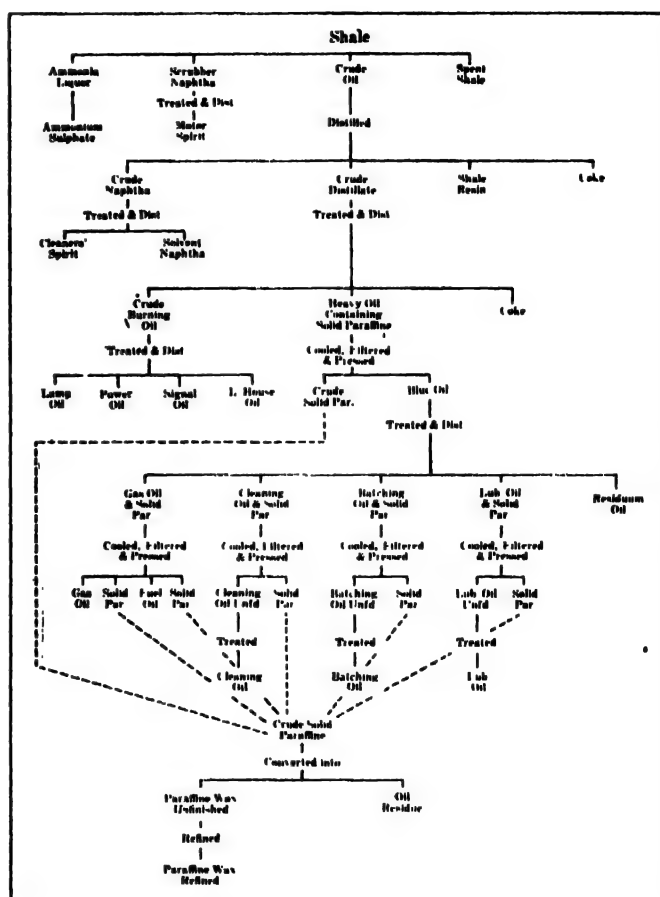

FIG. 1. FLOW SHEET OF SCOTCH REFINERY OPERATIONS

in that condition and contain from 6 to 10 per cent of fixed carbon the fuel value of which would be wasted. The use of steam, as described, cools the shale, while heating the steam, thus carrying heat back into the retort; in addition, the steam and fixed carbon in the shale react, producing a gas of good fuel value, since it is composed mostly of hydrogen and carbon monoxide, thus utilizing much of the fuel value of the fixed carbon in the spent shale. As the carbon is burned out, ammonia is produced, and the excess steam and other gases protect the ammonia from decomposition at the high retort temperatures, and sweep it at once into the cooler zone. Oil production in the upper part of the retort goes on slowly and oil vapors made are at

once swept away to a cooler zone and out of the retort by the excess steam and gas, thus effectively protecting the oil from excessive decomposition.

BYPRODUCT AMMONIA

The question of producing ammonia from oil shale is one that has been discussed at considerable length by those interested in oil shale in this country. The average American oil shale compares favorably with Scotch shale in nitrogen content and it is to be expected that the nitrogen in both shales can be recovered with equal ease. The general tendency among American oil-shale processes seems to disregard ammonia recovery except the small amounts incidentally produced in ordinary dry destructive distillation. It is felt by many that the conversion of the nitrogen in a rich oil-yielding shale into ammonia is not a desirable thing, as such conversion would reduce the retort capacity for oil. While this is probably the case, there is nevertheless a fair probability that the increased returns made by producing ammonia would more than counterbalance the decreased oil-producing capacity of the retort, assuming a satisfactory market for the ammonia exists. This may particularly apply if it is found that steaming the retorts is necessary to produce the best grade of oil. To produce maximum economic yields of ammonia from oil shale, Scotch operators find a maximum temperature of about 1,500 deg. F. and an excess of steam necessary. While 900 to 1,000 deg. seems to be the highest temperature necessary to produce oil from oil shale, the increased heat needed to produce the ammonia is nearly if not completely supplied by the combustion of the gas produced by the action of steam on the carbon of the shale in the ammonia-production part of the retort.

The use of steam in retorting is said by the Scotch operators to increase the yield of ammonia over two and one-half times the amount recovered by straight dry destructive distillation. In discussing the ammonia-recovery problem, it is necessary to point out the possibility of recovering part or all the nitrogen of the shales in some form other than ammonia, such as pyridine compounds and the like, and also the conducting of the oil-recovery and nitrogen-recovery operations in separate and more or less independent apparatus. Both of these possibilities require thorough study, and whatever is done in the way of recovering nitrogen must take into account the main purpose of oil-shale treatment—that is, oil production.

QUALITY AND QUANTITY OF YIELD

The writer has examined oils from Scotch plants and oils produced by different processes from various American shales, and has found that the quality of the Scotch oil is in every way much better than any oil he has thus far seen from American shales. Whether this is mostly due to the nature of the processes or to the shales themselves he is not definitely prepared to say, although it is known that the conditions under which oil is produced from shale have a very decided influence on the quality and quantity of oil yield. However, it has also been determined that different shales, retorted under identical conditions, do yield somewhat different oils. Both factors undoubtedly influence the quality of the oils yielded to a considerable extent.

The problem of those working in oil shale seems to be the production and subsequent refining of the best

possible quality of shale oil consistent with economic practice. Once these conditions have been determined, they must be controlled and held as uniform as possible in commercial practice. The quality of oil produced will perhaps depend on the kind and amount of products desired, but it seems that the crude oil should be obtained in as undecomposed or uncracked state as possible. This has plainly been the aim of the Scotch operators. Every successful change in Scotch retort design can be noted in the greater production of burning oils and wax from the Scotch crude, a plain indication of less cracking.

Perhaps, in the United States, it may be desired to obtain a greater yield of gasoline or light oils by cracking the crude shale oil. Even then it would appear that the crude should be obtained from the retort in as uncracked a state as possible, and only those fractions of the crude most adapted for cracking be so treated. Cracking the crude itself, either during production or subsequently, can reasonably be expected to yield more light oils, but at the expense of some of the desirable heavy fractions of the crude. The production of a crude yielding a maximum amount of gasoline directly from the retort is thus apt to be a decidedly wasteful and uneconomical practice and moreover likely to yield a very unsatisfactory grade of gasoline, since the cracking of the crude during production cannot be so easily controlled as the cracking of a selected fraction in a separate apparatus designed solely for cracking, where exact control is possible.

As a rule, American shale oils thus far examined differ from the Scotch crude in that the former are heavier (specific gravity 0.900 to 0.980) than the latter (specific gravity 0.875), fractions from the former are more highly unsaturated and the odor more disagreeable than those from the Scotch crude. The American shale oils thus far examined were of a mixed paraffine and asphalt base, while the Scotch oil is distinctly of a paraffine base. It may not be possible to make as good oils from American shales as from Scotch shales, possibly because of the nature of the shales themselves, but undoubtedly better oils can be made than are being produced here today once the proper study of retorting methods has been conducted.

Oil production from oil shale is a process of destructive distillation which is not a haphazard affair, but one which must be properly controlled if good results are to be obtained. Obviously there are certain factors influencing oil production from shale, and for any shale the proper thing to do is to determine optimum conditions for producing an oil which will yield the greatest profit.

FACTORS INFLUENCING YIELDS

The Bureau of Mines, in co-operation with the State of Colorado, is investigating certain of these factors in its investigation at Boulder, Col., on Colorado oil shales, with the idea that best conditions, as determined from small-scale experiments, will later be applied commercially in so far as commercial considerations permit. Some of the factors which can be expected to influence oil yield and quality, and the influence of which should be studied, are set forth below.

- a. Size of shale particles treated.
- b. Thickness of charge in the retort.
- c. Rate of rise of temperature of the charge.

d. Maximum temperature to which shale is submitted.

e. Time of contact with and maximum temperature to which vapors are submitted.

f. Effect of steam and other vapors and gases.

g. Pressure under which retorting takes place.

If greatest economic returns are to be obtained from oil-shale operations, the effect of such factors as these should be determined.

Figs. 3 and 4 show, respectively, the retorting and laboratory equipment established at Boulder in connection with the above-mentioned investigation.

THE SHALE OILS

Once the oil is produced, it must be studied to determine its refinability. The high refining loss incurred in Scotch operations has been noted, and efforts should be made, of course, to keep this figure to a minimum in the refining process. New processes of refining and treating may be worked out when the oils produced are thoroughly studied and tried out in commercial operations. The Bureau of Mines, at its Salt Lake City Station, in co-operation with the State of Utah, is studying the oils produced from various shales and by various processes, correlating its work in this regard with the co-operative work in Colorado.

All American shale oils thus far studied by the Bureau are highly unsaturated and contain a considerable amount of nitrogen bases. Some of the unsaturated compounds can probably be allowed to remain in the finished products, but others polymerize and deposit gums and resins which must be removed in refining. The use of steam in Scotch retorts seems to prevent the occurrence of nitrogen bases in the oil to a large extent. It seems that ordinary methods of refining petroleum will have to be modified for shale oil,

and such modification can be the result only of thorough study of the oils themselves.

Particular attention is directed to the high loss incurred in refining Scotch shale oil. The refining loss, as has been noted, amounts to about 23 per cent of the crude treated. Thus, although average Scotch shale yields about 24.5 gal. of crude oil to the ton, only about 20 gal. of this is marketed. As compared with this high loss, the average loss in straight run refining of petroleum in American practice does not exceed 3½ or 4 per cent. If the shale oils thus far examined by the Bureau of Mines are a fair indication of what can be expected from American shales in commercial operations, apparently the loss in refining them by Scotch methods would amount to nearly twice the loss in refining Scotch shale oils. If ordinary petroleum-refining methods are used, probably the loss would be still larger.

Oils are refined for the purpose of making marketable products from them. In refining operations undesirable or offensive substances are removed from the oils in order to make the finished products acceptable to the consumer, but in refining oils which suffer high refining losses, such as shale oils, it is probable that not only are objectionable substances removed but a considerable amount of material which might be retained in the finished products to good advantage.

Therefore probably a major problem in shale-oil refining is the reduction of refining losses, either by the development of new or modification of old methods. Such development or modification can come only as the result of technical study of the oils.

A refinery loss is a loss from more than one standpoint. In the first place, there is an actual loss of material, and in the second, treatments in which losses are incurred are more or less expensive. So the refiner not only loses a part of his oil but pays for losing it.

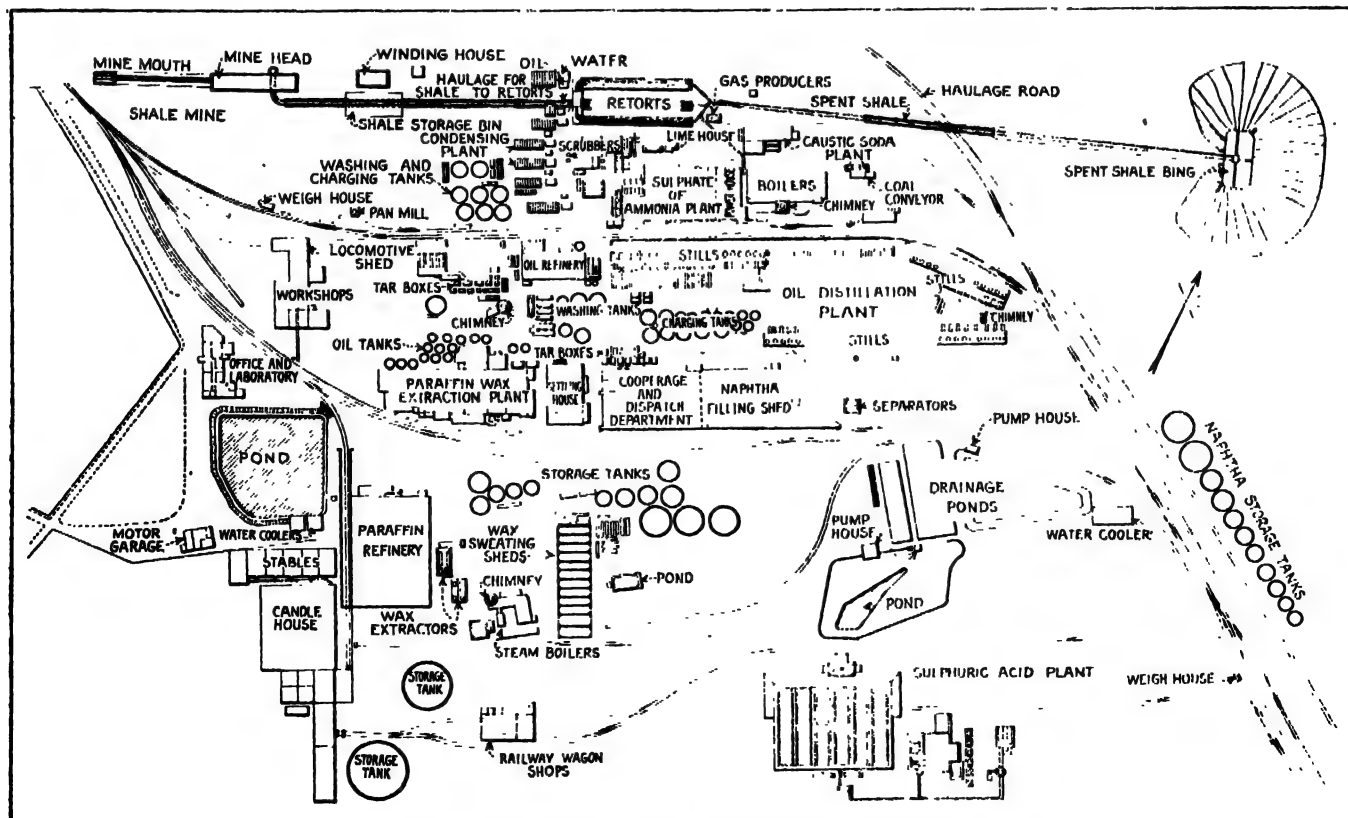

FIG. 2. PLAN OF TYPICAL SCOTCH SHALE WORKS

FIG. 3. OIL-SHALE RETORTING EQUIPMENT AT BOULDER, COL.

A large part of the refining loss in any event will probably be in the form of acid and alkali tars, and a field of research to utilize these tars is plainly indicated.

This discussion is intended to call attention to the fact that conditions of retorting and refining should be worked out on a scientific basis if maximum returns are to be expected in oil-shale operations. Each operator should know with scientific accuracy the optimum conditions for treating his shale and refining his oil. The chemist and chemical engineer will probably have a greater field for research in oil-shale operations than in petroleum production and refining. Particularly the oils need study. It is not possible to predict with accuracy the possible profits a plant can expect, or its costs, until the quality and quantity of products of marketable value it can make are known, as well as the conditions under which they can be made and refined.

When the problem of producing satisfactory products has been solved, there may be a field for research in the study and production of byproducts. Discussion of byproducts seems premature now, it is true, but later the oil-shale industry may develop an important byproduct industry. As a matter of fact, few realize the importance of the present petroleum byproduct industry.

When the Scottish oil-shale industry was started, economic conditions were such that the oils produced could be marketed with profit, but these conditions have changed, and since about 1864 the industry has been successful only because of continual improvements that have been made in the technology of shale-oil production and refining. In this regard, Steuart¹ writes:

"The Torbanehill mineral" yielded the raw material

for about a dozen years, much of it being used in Scotland and some being exported to America and the Continent for distillation.

"In 1862, the supply from this source was being exhausted, and the material became too valuable and expensive for this industry, hence shale was resorted to, but with widely different results. While the Torbanehill mineral yielded about 120 gal. of crude oil per ton, the shales first used furnished 40 to 50 gal. and soon the yield was 30 to 35 gal. The expiry of Young's patent in 1864 led to a rapid expansion of the Scottish oil industry, but ere long it sustained a severe check. The discovery in 1859 of oil wells in Pennsylvania by E. L. Drake was soon followed by the importation of petroleum lamp oil into Britain, the quantity increasing year by year. Owing partly to this competition and partly to the increase in the number of oil works, prices gradually fell. . . .

AMERICAN AND RUSSIAN COMPETITION

"At first the Americans exported to Britain only burning oil, but they soon began to introduce supplies of lubricating oil and subsequently of solid paraffine. Then the smaller works (whose retorts had been mostly for the production of burning oil) tended to decrease in number, and the larger ones to increase in size, thus concentrating and cheapening production. Retorts were improved to suit the circumstances, and to produce a purer oil with a larger proportion of heavy products. Mechanical labor-saving arrangements were devised, refining was improved and cheapened, and economies of every kind were introduced. The chemicals used in refining were recovered; and the tars separated by them, the removal of which had involved expense, now became a source of profit as fuel. The supply of Peruvian guano began to fail, hence the price of sulphate of ammonia rose to £22 (1880) and even to £24 per ton; but as the importation of nitrate of soda increased greatly, it fell below £8 per ton about 1890, when burning oil sold at less than 6d. per gal. These conditions led to further concentration. Retorts especially designed for the manufacture of sulphate of ammonia were universally adopted, and improvements were introduced to secure greater economy of working. With the older type of retorts a shale had to yield about 30 gal. of crude oil per ton in order to be profitable; but with the new retorts, and the increased yield of ammonia and fuel gas, a shale furnishing 20 gal. is remunerative. Not more than 16 lb. of sulphate of ammonia per ton was formerly obtained as a maximum, now 35 to 70 lb. is got, according to the quality of the shale. By these methods the quality of shale that can be worked with profit has been increased and the life of the Scottish industry has been lengthened.

"Since 1873 the Russian petroleum industry has developed rapidly, and in recent years competition from this source has become very severe. Russian crude oil, however, produces no solid paraffine; and America shows signs of not being able to respond as easily as formerly to the increased demands of the world for petroleum, any increase in American output being fuel oil. In 1905, however, it succeeded by great effort in making up for the Russian deficiency caused by troubles at Baku. In 1909 and 1910 there was a definite decrease in the export of burning oil from America to Britain. Sulphate of ammonia is being produced in greater quantities from iron works, coke ovens, Mond gas producers, etc.; but the demand also increases. New competitors are always

¹Steuart, D. R., "The Oil Shales of the Lothians"—Part III. "The Chemistry of the Oil Shales." "Memoirs of the Geological Survey," Scotland, pp. 137-138.

²A very rich oil shale.

arising; recently, for instance, Galicia with solid paraffine, Rumania with burning oil, and the Dutch East Indies with motor spirit. But notwithstanding this prolonged and fierce struggle for existence, the Scottish industry still survives. The Scottish companies vie with one another in their efforts to improve and cheapen the processes, and show signs of mutual helpfulness and co-operation. In the early days of the industry operations were carried on in a simple but expensive fashion. Sometimes the shale was carted miles to the retorts, and the crude oil carted miles to the refinery, and breaking shale, pumping oil, etc., were done by manual labor. But through all these years evolution has been at work in developing a high state of organization, resulting in economy and efficiency. The most of the existing works have adopted electricity for lighting and for the conveyance of power for all purposes.

"In 1894 there were thirteen oil companies in Scotland; now there are only seven (three of which produce crude oil only), but the output has not been reduced."

NEW AND IMPROVED PRACTICE BEING DEVELOPED

Thus there is seen the continual application of new and improved practice in the Scotch industry, a practical seeking after better methods, perhaps not by means of strictly scientific research, but nevertheless by research, which, conducted in a practical manner and with a definite objective in view, has kept the industry alive. It may be noted that the only companies in Scotland which have survived during the long years of competition have been those which could afford to experiment and had the capital at hand to conduct operations in a large way under the supervision of trained technicians and executives. Once a market had been established for certain products, efforts have continually been made to increase the yield of these products and lower production cost.

The oil-shale industry in this country will afford a field for the mining and mechanical engineer, as well as the chemist and chemical engineer. Mining the shale is bound to furnish a very important item in the total cost of producing refined shale-oil products. In Scotland the cost of mining the shale is well over 50 per cent of the total cost of making refined shale oils. The mining of oil shale in this country should offer the mining engineer an opportunity to devise new methods of drilling, breaking down, hoisting, conveying, crushing and the like, and permit the reduction in total costs by supplementing high priced mine labor with mechanical devices.

RETORT CONSTRUCTION

Retort construction is a problem for the mechanical and chemical engineer. The Scotch retort, when carefully examined, is found to be admirably suited for its task. A notable feature in its design is the manner in which provision is made for the expansion and contraction of each retort in a unit, independently of any of the others. The average life of the best types of Scotch retort is well over twelve years; the value of this figure can be appreciated when it is learned that the life of the first retorts used was only one and a half to two years. The mechanical engineer may be asked to adapt the Scotch retort to American shales, and the writer believes it to be capable of considerable modification for certain definite purposes. Its freedom from complicated mechanical devices, long life and satisfactory performance for so many years in Scotland make it difficult to

FIG. 4. OIL-SHALE LABORATORY AT BOULDER, COLO.

disregard for use in this country without complete trial. A shale retort must be rugged enough to operate continuously for long periods at comparatively high temperatures handling an abrasive material. As has been the case in coal byproducts plants, the engineer may be able to substitute ordinary firebrick with other refractories, such as silica brick, and there may be a new field for the use of alloys and metals with protective coatings designed to resist oxidation at high temperatures. In the refining of the oils it is expected that while much of the ordinary petroleum-refining equipment can be used, probably much of it may have to be modified, and there are distinctly seen the possibilities of new refining processes, equipment for which the chemical and mechanical engineer will be called upon to supply.

SUCCESS AHEAD

The future of an oil-shale industry in this country is practically assured by the increasing consumption of petroleum and its products in this country over domestic production of petroleum. Indications are that in the comparatively near future the United States must import the bulk of its petroleum or find a substitute or new source of hydrocarbon oils. While possibilities in the use of such substitutes as alcohol and coal-tar products cannot be disregarded, the writer sees in oil shale the natural and logical source of oils to make up in large part the coming deficit between domestic consumption and production of natural petroleum. It seems certain that motor fuels, burning oils, fuel oils and paraffine wax can be made from shale oil, but there is considerable doubt as to the possibility of producing more than moderately viscous lubricating oils from them. Between the knowledge that certain oils can be produced and their actual commercial production is a large gap which must be filled by properly directed research and investigational work. There are reasons to believe that a company, well organized, with plenty of capital and well equipped with business and technical men, if situated favorably, would have a reasonable chance of establishing successful commercial shale-oil production, if not at the present time, at least in the near future. The necessity for technical investigations and control, however, cannot be too strongly emphasized, because the oil-shale industry, in its final analysis, is nothing but a low-grade raw material chemical manufacturing enterprise, which, when economic conditions are right, depends on capital and business and technical ability for success.

*The largest of these consolidated into one company, Scottish Oil, Ltd., in 1919.—AUTHOR.

AN INDUSTRIAL RESEARCH LABORATORY DEVELOPED FROM AN OLD MILL IN A FAVORABLE LOCATION

A Novel Laboratory for Industrial Research

A Description of a Research Laboratory Organized to Study and Develop New and Economical Problems Relating to Chemical and Metallurgical Processes and Equipment, With a Succinct Enumeration of Some of the Problems Which Are Being Studied

WE HAVE been preaching the doctrine of intelligent research in industry so earnestly that it is always a pleasure to tell of the successful operation of a laboratory devoted to the purpose. Of course, a laboratory is only a shell; it is the men in it that count; but wisdom begins in regard to this subject with the selection of the men, the selection of the subjects for research and the establishment of proper facilities and surroundings for the work. Certain principles seem to be pretty well established: The men engaged in research must not be taken from their work to do incidental testing for production control; they must not be teased and hectorred by problems of administration; their business is abstract thinking and corroborative testing, and these things are incompatible with union hours, the time clock or the whistle.

In a way, of course, research is speculative, but the word needs qualification. Anybody with money in the bank can speculate if he wants to but the number of persons who can engage successfully in true research is severely limited. This calls for constantly more and more specialized knowledge, and the laboratory which the writer is about to describe was organized to study and develop new and economical methods for the separation of particles in suspension and for their more intimate admixture. The special requirements necessary for work in this field were happily already possessed by the Dorr Company's scientific staff, inasmuch as the field in question indicates the general scope of the Dorr apparatus. But the successful operation of the laboratory staff in the solution of problems within the domain

mentioned has led to the undertaking of work quite outside of these limitations, so that its scope has been greatly extended beyond the original plans for the establishment.

A research laboratory differs from everything else under the sun. Generally speaking, the more we know of a thing the better can we tell what it will do or accomplish. With a research laboratory, however, the more scholarship and scientific understanding we bring to it the less can we tell what will come out of it.

The metallurgical and chemical apparatus invented by J. V. N. Dorr have been fully described in previous issues of *CHEMICAL & METALLURGICAL ENGINEERING*.

They were thoroughly established in the cyaniding industry, but the inventor set himself the problem of introducing them generally into industry wherever a use for them might be found. Outside of cyaniding they were practically unknown until Mr. Dorr moved East from Denver, leaving a metallurgical branch and testing laboratory behind him when he established headquarters of the company that bears his name in New York, and surrounded himself with a competent scientific and technological staff.

NECESSITY OF RESEARCH APPARENT

At this point the necessity of research became evident to fill in the gap between Why and How. It was easy enough to ask, for instance, why wouldn't a thickener

¹"The Use of Hydrometallurgical Apparatus in Chemical Engineering," by John V. N. Dorr, January and February, 1915, pp. 55-59 and 91-98.

clarify the waters coming from an anthracite coal washer, save the coal and avoid the pollution of streams? But you can't sell apparatus or anything else on a question. Men of affairs are singularly averse to buying problems. On the other hand, if you can tell them how to solve their problems they become interested immediately. Here is the direct incidence of research. And very fortunately the substance of the little homily at the beginning of this article in regard to the subject was clear in the mind of the inventor. He wanted a place where work might be done in peace and quiet, apart from noise and distractions, and where the men at work would be free from the misery of a high-rent time clock to worry them to undue speed or omissions. It is remarkable how closely allied is academic calm to industrial research. The very thing to avoid is the slap-dash bustle and the emphasis of so-called "scientific" management in such a laboratory. If a man can think better when he dawdles with his figures there is no reason why he shouldn't dawdle with his figures. If the man in authority lacks scientific understanding his only safety is to leave the place alone. It is much better for such a person to say his prayers over the laboratory than to give instructions in it.

OLD MILL BECOMES A LABORATORY

Mr. Dorr purchased for the use of his organization an old mill at Westport, Conn., built way back in the seventeen hundreds, with good water power and about thirty-five acres of mostly wooded land. The mill was

200-FT. DORR THICKENER

reconstructed for laboratory purposes and for semi-commercial and commercial testing. It was provided with a considerable variety of small, medium and some full-sized apparatus for grinding, separating, drying, etc., besides a good metallurgical outfit, and an extensive chemical and a fair physical laboratory equipment.

An excellent library is provided with a big fireplace and comfortable chairs and tables, there are comfortable sleeping-rooms, and—the writer is speaking from experience—a grand breakfast may be prepared there. There are trout in the stream which runs under the mill, the woods about it are a bird refuge, and near by a couple of houses are approaching completion for the greater convenience of those engaged there. The place is forty-four miles from New York and about four miles from South Norwalk, which is an express passenger station on the New York, New Haven and Hartford

R.R. The laboratory has a permanent staff of four research engineers, together with attendants and laborers, and usually there are four or five more chemists or engineers trying out new ideas, or working on improvements in methods of separation or mixing, or in research along other lines. These extra men may be members of the company's own staff or from those of its clients.

SOME OF THE PROBLEMS STUDIED

The scope of the work undertaken at the laboratory may best be set forth by a list of the subjects of some of the problems already studied, and it also indicates how far beyond the original field of wet metallurgy the use of these apparatus has been brought by the application of intelligent research. The list includes: Leaching copper and tin ores, flotation of copper, tin, iron and lead ores; studies in connection with the production of Chilean nitrates, clays, bauxite, alum, feldspar, iron ores, phosphoric acid, acetylene, abrasives, coal, cement, dye wastes, fluedust, kaolin, lithopone, limestone, magnesia, oils, paper pulps, paints and pigments, rubber, starch, sewage, soap, etc. A curious example of research in this laboratory was one which resulted in an advance in the technology of making false teeth.

OPERATIONS OF THE LABORATORY

The operations of the laboratory may be divided under the following main headings:

Research dealing with the development of the company's ideas in connection with processes and equipment;

Research for clients often along lines which do not involve the use of the company's apparatus; and

Testing for the enlightenment and instruction of the sales forces.

Experience has demonstrated that what may appear to be a simple testing problem generally calls for careful research before a definite report can be rendered, and in view of this the company has adopted the policy of charging for all but those forms of simple testing in relation to sales which do not in any way call for analysis or research. Here we have an excellent example of laboratory growth: starting as a testing out plant to aid sales, as its competence develops it becomes a commercial laboratory. And the policy of charging for the study of manufacturers' problems enables the corporation to avoid tacking the cost of special research on the price of apparatus. It also makes it possible to maintain standard prices for apparatus.

Wholly apart from the services mentioned the laboratory plays a further important rôle as a mistake eliminator.

SOME OF THE THINGS ACCOMPLISHED

Some of the things accomplished that began in the laboratory as ideas which were tested out on a theoretical scale and later developed in part in the apparatus installed and in part in field work are the following: The art of "closed-circuit grinding," for instance, was well known in wet metallurgical work, but new to chemical technology outside of that domain. It needed the laboratory to demonstrate its usefulness in such industries as the production of pigments, floated silica, milk of lime, etc. Here, too, the idea was first considered to use thickeners to recover the dust from blast-furnace gases in which up to 47 per cent of iron is entrained. The method of introducing Dorr apparatus into clay

industries was worked out here, as also the saving of large quantities of coal from anthracite washeries, already referred to, and, at the same time, avoiding the pollution of streams. One of the sequelæ of this work was the establishment of a branch office in Scranton, Pa. A later development is in the bituminous washeries, also saving coal and avoiding the pollution of streams. It required preliminary testing to prove the use of apparatus in cement mills and in the separation of fine phosphate rock from clay. A major problem had to do

REVOLVING SCREEN FOR TRADE WASTE

with the handling of hot saccharate in the Steffens house of beet sugar establishments and for concentrating this precipitate under conditions of heat control prior to filtering, and for thickening the first carbonization precipitate. An allied problem worked out and successfully put into practice in the operation of a cane-sugar mill was the production, without filtration for subsequent evaporation, of a bright juice which is practically free from suspended solids. An unlooked-for secondary result which developed in field tests was that the underflow was much denser (liquid : solid ratio) than is otherwise obtained. This promises to eliminate a second decantation, which is a fertile source of loss.

IMPROVED TREATMENT OF SEWAGE

Another field in which research in the improved separation of solids from liquids was indicated and begun was in the treatment of sewage. The work started several years ago with problems relating to trade wastes which led to the development of a self-cleansing rotary screen, and this in turn warranted an attack upon the great question of the disposal of domestic sewage. Success in handling trade wastes led to the organization of a special sanitary department of the Dorr Company.

The domestic sewage problem is so pressing that it will probably be of interest to indicate the incidence of the work, although a complete solution of the problem is not yet at hand. When stream pollution is to be avoided, an affluent of high purity is required, which will be allowed to flow away without nuisance resulting. A desirable method of producing this purification is to activate the sewage—that is, to bubble air through it until oxidizing bacterial cultures are formed which destroy and absorb the offensive matter in the sewage. A clarified stable water effluent is produced, the impuri-

ties being separated in solid form by settling as "activated sludge."

The great difficulty with all sewage activation processes is that they require so much air that the factors of cost and time become a heavy burden. The new revolving screen operates in conjunction with this process by removing the sizable tough and non-digestible solids from the raw sewage prior to activation, thereby lessening the purification work of the bacteria. The activation takes place in a specially designed clarifier (or thickener) which effects distribution of circulation of the air bubbles in one chamber and separation of sludge from clear effluent in another. The indications are that aeration may thus be accomplished in less time and at lower expense than by other means. The aerated sludge then passes to final treatment.

Undeveloped as yet, but making progress under the auspices of this company as well as in other research laboratories, is the biological treatment of the sewage so that it shall have enough nitrogen when dried to be a high-grade rather than a low-grade nitrogen fertilizer. Dried activated sludge is not a nuisance. The other features, the removal of grease by mechanical means, the immediate treatment of sewage as it flows from the sewer and before it has become septic, with the avoidance of great settling tanks; the enclosed, unsmelled and unseen mechanical treatment from start to finish; the chlorinated clear and harmless effluent that flows away and the dried sludge fertilizer brought out as the final product of one operation, all push along toward the solution of these perplexities. The research of this company's group of chemists and engineers, in conjunction with the work done by others during the past twenty-five years, leads to hope that the Desired Thing is not far off: the inoffensive disposal of municipal sewage, an end to the pollution of surrounding waters and neighboring streams, the resolution of a present danger to health into an inoffensive sanitary disposal plant; a boon to agriculture and a source of profit rather than an expense to municipalities.

Research and Industrial Wastes

In a paper read by George S. Hessenbruch at the Indianapolis meeting of the American Society of Mechanical Engineers the following points were emphasized: In many instances the financial returns from the wastes when properly processed and obtained from the raw materials in a manufacturing plant have been greater than the return from the actual manufactured article made in the same plant. Today we are confronted by the cry of increased production. Every manufacturer is striving his utmost to help this movement. In fact it is the solution or at least an amelioration of many of the evils that threaten us seriously, and it is natural to turn toward the utilization of wastes and waste materials, which is the most economical and beneficial way to help this movement. Reducing the wastes or utilizing them in some way or other by suitable processing will not only save the national resources from being depleted more rapidly, but it will also reduce costs, establish new industrial undertakings, give employment to more people, open up new channels of commerce and induce capital to invest in new enterprises. The meaning of all this is fully realized and industrial as well as pure scientific research is gradually receiving more and more attention.

GENERAL VIEW OF CLINCHFIELD PLANT

Low-Temperature Carbonization of Coal and Manufacture of Smokeless Fuel Briquets

Low-Temperature Carbonization of Coal Compared With High-Temperature Carbonization—
The "Carbocoal Process," Retorts, Machinery, Etc.,
Installed at the Clinchfield Plant

BY HARRY A. CURTIS, PH.D.*

THE conversion of bituminous coal into a smokeless fuel by any commercially feasible process is a project of first-rate importance, not alone because of the interesting engineering and chemical problems involved but also on account of its vital economic bearing.

LOW-TEMPERATURE CARBONIZATION COMPARED WITH COKE-OVEN PRACTICE

When a given coal is distilled or carbonized, there are several factors which influence the quantity and the composition of the various byproducts, but of these factors temperature is the dominant one. In the ordinary byproduct coke oven, where the prime object is to turn out a special product for the metallurgical industry, the carbonization is carried out at a temperature far above that which is favorable to a high yield of oils. The resultant coke is too inert and too high priced a product to find favor in the domestic fuel market or in the industries generally.

If coal be carbonized at lower temperatures, say at about 900 deg. F., the yield of oils per ton of coal will be more than doubled, while the gas yield is correspondingly much less. If a coal of the following proximate analysis be used

	Per Cent
Volatile matter...	35
Fixed carbon...	58
Ash...	7

the yield of the various products will be as follows (assuming that a coke oven could handle so high volatile a coal):

	High Temp. 66 (10% volatile)	Low Temp. 72 (10% volatile)
Coke residue, per cent	10,000	4,000
Gas, cu ft	12	24
Tar, gal	3	13
Light oil, gal	20	10
Ammonium		

The coke residue in the two cases will be quite different in character, the higher-temperature product being harder, coarser grained and more inert in the fire, while the low-temperature residue is light, relatively soft, friable and easily burned.

The high-temperature carbonization in the coke oven yields much more gas than does low-temperature carbonization, but the coke-oven gas will be lower in average heat value, say 550 B.t.u. as compared with 750 B.t.u. for the low-temperature process. This difference is, of course, due to difference in composition, the low-temperature gas corresponding more nearly to that which is produced in the coke oven during the earlier stages of coking.

The tars produced are quite different in composition. An indication of this is that while the specific gravity of good coke-oven tar will run about 1.17 at 60 deg. F. and the tar will show a free carbon content of about 6.5 per cent, the low-temperature tar will run less than 1.1 specific gravity and have a free carbon content of less than 1 per cent. In general, the low-temperature tar contains more paraffine bodies and less aromatic

*Chief Chemist, International Coal Products Corporation.

compounds than does coke-oven tar, but the tar acid content of the low-temperature tar is higher. For example, on distilling the tars, the 170 deg. to pitch fraction of the low-temperature tar will contain about 40 per cent tar acids, while the distillates from coke-oven tar will run less than 15 per cent tar acids. The low-temperature tar distillate contains only a trace of the phenol which is characteristic of coke-oven tar, but the "phenol coefficient" of the low-temperature tar distillate will run higher, due to the fact that the cresols are more powerful disinfectants than is phenol. Naphthalene is evidently a high-temperature product, for it is absent in the low-temperature tar.

The light oil recovered from the gas in low-temperature carbonization differs from that obtained in coke-oven operation in that the former contains about 20 per cent of paraffines mixed with the usual benzene, toluene, etc. In war times, when pure benzene and toluene are needed, this is a disadvantage, since the paraffines must be removed, but in peace times, when this oil will normally be worked up into motor spirits, the presence of the paraffines is an advantage because it lowers the freezing point of the mixture, whereas the corresponding product from the coke oven must be mixed with gasoline for winter use.

The ammonia produced in low-temperature carbonization is only about half that yielded by the coke oven. It is known that when coal is distilled, evolution of ammonia begins at about 650 deg. F. and practically ceases at about 1,450 deg. F. The distillation at an intermediate temperature, 900 deg. F., without steaming, necessarily gives a low yield of ammonia.

THE "CARBOCOAL PROCESS"

The Carbocoal process for producing an anthracite-like fuel from bituminous coal is not purely a low-temperature process, since the soft semi-coke obtained in the initial low-temperature carbonization is subsequently briquetted with pitch and then carbonized at a relatively high temperature. This point should be borne in mind in comparing the yields of the Carbocoal process with simple low-temperature processes. Also it is not correct to compare the yields of the Carbocoal process directly with the yields of the byproduct coke oven, for while the tar from a coke oven is marketed as such, in a Carbocoal plant the tar is distilled

FIG. 2. FEED AND DRIVE MECHANISM

and the pitch returned to the process, tar oils being marketed in place of tar.

In the Carbocoal process the coal is first crushed to pass a 1-in. screen and is then fed by screw conveyors into horizontal retorts. Each retort is about 7 ft. in diameter and 20 ft. long, lined with carborundum and carrying two heavy paddle shafts running lengthwise through it. Each shaft carries about forty paddles, so arranged that when the shafts revolve the paddles stir the coal continuously and advance it slowly through the retort. The advantage of moving the coal up to the hot walls of the retort instead of depending on the transfer of heat through the coking mass is obvious.

The yields obtained in this step of the process are those represented under low-temperature carbonization discussed above—i.e., about 4,000 cu.ft. of rich gas, 24 gal. of tar, 1½ gal. of light oil and 10 lb. of ammonium sulphate.

The semi-coke which is continuously discharged from the retorts may be used directly under the boiler of a power plant or may be charged directly into a gas producer. It is, however, not in shape to market for general use, being too soft and carrying too many fines. In the next step in the process this soft semi-coke is ground and briquetted with hot pitch, heavy roll presses being used for this work. These raw briquets are like the usual smoky coal briquets which have done much to prejudice the market against briquetted fuel. In the next step in the process, the raw briquets are charged into inclined rectangular retorts and carbonized for about six hours at 1,800 deg. F. During this time the briquets shrink about 30 per cent in volume, the pitch binder is coked, and the hard, dense briquets resulting finally are quite smokeless when burned.

The high-temperature carbonization results in a further yield of byproducts—viz., about 6 gal. of tar per ton of coal, about 5,000 cu.ft. of gas, an additional 10 lb. of ammonium sulphate and a little more light oil.

In a Carbocoal plant, the byproducts from the primary or low-temperature carbonization are combined with the corresponding byproducts from the secondary or high-temperature carbonization, and worked up as usual.

In order to compare the output of a Carbocoal plant with that of a byproduct coke oven, it may be assumed that the tar is distilled in both cases, the pitch in the case of the Carbocoal process being turned back. In the accompanying table the pitch from coke-oven tar

FIG. 1. BATTERY OF SIX LOW-TEMPERATURE RETORTS IN COURSE OF CONSTRUCTION

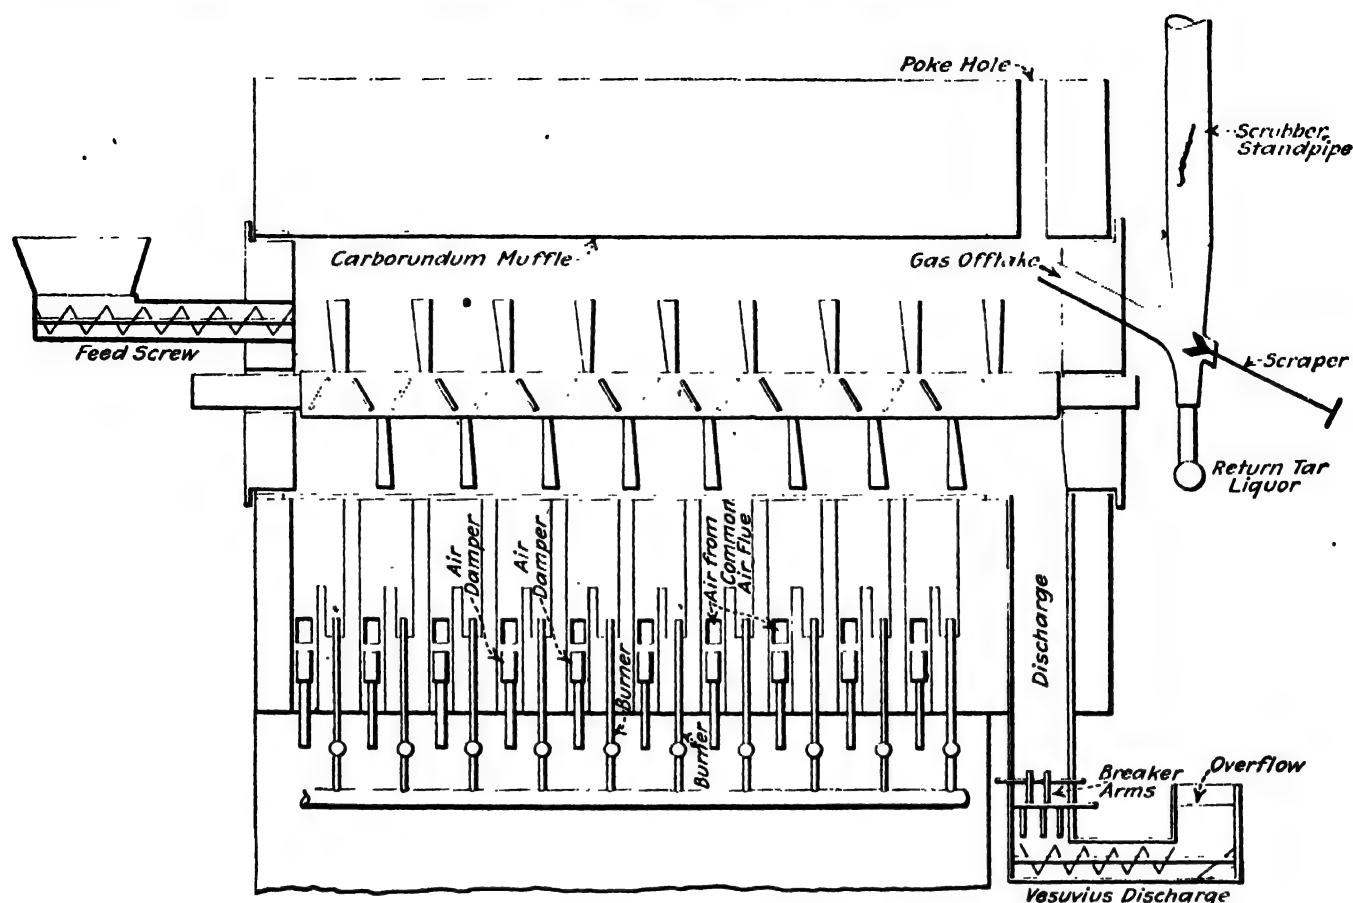

FIG. 3. CROSS-SECTION OF PRIMARY FURNACE

is taken at 68 per cent the volume of the tar and the pitch from the Carbocoal process at 50 per cent the volume of the tar. The yield of Carbocoal will be a few per cent higher than the coke for two reasons—one that the Carbocoal still carries 3 to 4 per cent volatile, and the other that the pitch used in briquetting yields some coke in the secondary carbonization.

YIELDS FROM A TON OF DRY COAL (See analysis in text)

	Coke Oven	Carbocoal Pro
Coke or Carbocoal, per cent.....	66	68
Gas, cu.ft.	10,000	9,000
Light oil from gas, gal.	3	2
Ammonium sulphate, lb.	20	20
Tar oils, gal.	3 8	15
Pitch, gal.	8 2	Used

The coal is assumed to have the analysis given earlier in this paper, which makes the coke-oven yields appear a little unusual, since a coke oven seldom uses so high volatile a coal.

THE CLINCHFIELD CARBOCOAL PLANT

The Carbocoal process¹ was developed during the past five years by the International Coal Products Corporation at its experimental plant in Irvington, N. J. Most of the work here was done with commercial-sized retorts, since it was clear from the nature of the problem that small-scale apparatus would not yield the necessary mechanical data on which to design a commercial plant. The experimental plant at Irvington has a capacity of about 100 tons of coal per day, but this plant is operated strictly for experimental and development purposes.

During the war the United States Government financed the construction of a 500-ton-per-day plant at Clinchfield, Va. This plant was finally put into operation in June, 1920, and has been running steadily since. Full-capacity production will be reached during the present summer.

The Clinchfield plant is equipped with twenty-four primary, or low-temperature retorts, each having a capacity of 24 tons of coal per day. The coal used is a good grade of bituminous coal coming from mines a few miles from the plant. After crushing, the coal is delivered to feed hoppers over the retorts from which it is carried into the retorts by self-sealing screw conveyors. The semi-coke is discharged continuously by similar self-sealing screws and falls onto closed conveyors which deliver it to storage bins in the briquet plant. Here it is ground, fluxed with pitch, and briquetted on heavy roll presses. The raw briquets fall onto a long, cooling conveyor and are delivered to storage bins at the secondary or high-temperature retort, whence they are charged into the retorts from steel larry cars.

There are ten secondary retorts arranged in batteries of six and four, each retort about 12 ft. wide and 20 ft. long, inclined at about 30 degrees and divided into six carbonizing chambers. After the final carbonization of about six hours at 1,800 deg. F., the finished briquets—Carbocoal—are discharged by gravity, quenched and loaded for shipment.

The byproducts are handled as in coke-oven practice, the Clinchfield plant including a complete byproduct plant, tar-distilling plant, light oil plant, power plant and all auxiliary equipment necessary to make it a self-contained unit.

The Chemical Profession—Its Opportunity and Responsibility

An Outline of the Growing Effective Effort of the Chemical Profession and of the Necessity and Duty of Chemists to Enlist Capital, Brains and Natural Resources for Concerted Action in the Development of the Chemical Industry

By R. S. McBRIDE*

THE chemical profession today stands at an open door of opportunity. Indeed, every indication of the times is an invitation to enter upon a new era of growth and achievement that is most alluring. With the opportunity comes also a duty. The duty is one requiring not only service but also expansion and growth of the profession in many lines. Never before has the chemical profession seen such an ideal blending of a promising future for itself with a splendid chance to render a large service to the world. The profession is young, but it deals with basic and essential activities. It goes into all branches of industry with far-reaching influence. No one can today prophesy the immediate opportunity, much less foresee the increasing power, of effective chemical effort properly developed in future years.

All of this would seem to be a statement of generalities of little interest or practical value if there were not at hand readily available means for the realization of these dreams. A simple analysis of professional activity makes many of these points clear.

THE BASIC CHEMICAL REACTION

Chemistry is principally applied for the control of industrial processes. In this application we can write one simple basic "reaction" which covers practically all of its activity.

Resource + process + labor and power + management and scientific skill + money = product + byproduct + profit.

This industrial reaction goes on successfully under a wide variety of conditions. American business methods and the atmosphere of American science seem particularly conducive to high yields of all of the products of the reaction. Particularly does skill in science and management furnish a splendid catalyst for the reaction.

THE YARDSTICK OF CHEMICAL SUCCESS

Measuring the speed of this reaction we cannot use the unit of product or unit of time, but we have two most effective yardsticks. The financial measure of success, of course, is expressed in terms of the dollar; and to the extent which the third product of the above reaction predominates, our financial and business interests would say that we had achieved success. On the other hand, we have the measure of scientific success. There is first the extent to which we have conserved our resources. There is also that measure of success which depends upon the improvement in quality of product or lessening the cost of a product of given quality. And the still more rigid test of achievement

is that we shall have furnished something novel which is useful either as a substitute in old work or for the accomplishment of new results.

PROFESSION OR TRADE

Chemistry is unquestionably practiced in this country as a profession. It has, however, many hangers-on who lend to it the characteristics of a trade. As a profession it believes fundamentally in the application of knowledge. In this it is distinguished from a trade, which inevitably rests largely upon the application of experience rather than application of knowledge. This distinction between profession and trade is fundamental. Without clear recognition of it the advancement of chemistry will be much handicapped and delayed. Fortunately, however, chemistry has through very recent years been granted a new vision which gives promise that it will recognize this distinction.

As a science, of course, chemistry dates back into early times, but modern chemistry has successfully avoided the pitfall of ancestor worship. It has taken all of the Anglo-Saxon characteristics of independence of thought and vigorous advancement of new ideals. There remains, however, additional responsibility. Particularly with respect to organized professional effort it has not correspondingly advanced.

ORGANIZED CHEMICAL DUTY

Turning back to the basic reaction of industrial activity, we should ask ourselves, What has organized chemistry done or what is it doing today in the direction and control of industrial reaction? To what extent has it gone into the market for capital, for brains, for natural resources? How has it encouraged the development of the process and machinery, patents and inventions? Wherein has it influenced the market conditions for its products and byproducts tending always to produce well-balanced industry?

In almost every case we are forced to reply that *collectively* chemists have done almost nothing. What might or should have been done is all too obvious to the careful student of the situation. In impetuous, youthful attack upon its everyday problems, however, the profession has ignored these duties and today seems to stand in need of reprimand. However, it is by no means too late to induce those efforts which will be effective in this work, for they are only latent in the chemical profession.

THE BID FOR CAPITAL

Chemical industry today is not recognized as such—that is to say, that potent element of industrial development, the financier, does not recognize chemical activity collectively as such. This is in striking con-

*Engineering Representative, McGraw-Hill Co., Inc., Washington, D. C.

trast with the railroads, the public utilities, the mining and metallurgical interests of the country. All of these and others go into Wall Street as a group and demand there and receive financial attention and backing. To date, however, the chemical profession has not developed a similar respect and attention for the chemical demand of the country.

Recently the electrical appliance interests of the country were urged to attend to matters such as this. Editorial comment to them emphasized: "Your banker is your best business friend. Get acquainted with him and see that your bank officials become acquainted with your business and with the facts about the great electrical industry of which your business is a part." The comment continued to set forth the more essential and less essential lines of electrical merchandise and supply that demand financial support during the coming year. The amazing total of estimated sales aggregated about two billion dollars in merchandise for 1920. Surely the chemical industries could make an even more impressive showing, but they have never even attempted such a demonstration.

The electrical business taken at large is regulated. Profits are severely limited in many lines by the price-fixing activities of our public authorities, and yet this business successfully commands the interest of the banker and his support. How much more readily the chemical industry, young, rapidly growing and prosperous as it is, can command this attention may well be appreciated. But not only is this opportunity greater, the financial demand is greater too, for it is the growing industry which needs the greatest amount of new capital. In greater proportion, too, is our responsibility for this important aspect of professional effort.

THE SEARCH FOR RESOURCES

The chemist should not be content to let the geologist, petrographer and mineralogist alone seek the resources of the country. He, too, must go into the field, not in person, perhaps, but by proxy, always seeking the natural industrial resource which is to be basic for his processes. Economic geology today is really resource chemistry. The industry of tomorrow must depend upon explored resource of today. Imports, exports, tariff and many other related questions are only beginning to receive their deserved attention by chemists. Individually we have begun to appreciate their importance. Collectively they are as foreign to the profession, it appears, as Greek or archæology.

PROCESSES AND MACHINERY

For successful development new processes and new machinery must continually be furnished. Only by individual effort and private support can invention be first conceived, but much of this invention which promises well for the industry will fail unless it receives more than this individual support. Full records of progress must be made in order to facilitate wider expansion, wider application of new developments must be always encouraged, and co-operative effort in support of new and worthy undertakings must never fail, if the chemical profession is most quickly to realize upon the new ideas.

Chemists must work together in these lines. They must co-operate to speed up the progress from research to achievement. This process is not simple, as we all know. Research leads to discovery. Discovery leads

to invention. Invention leads to development. Development leads to industrial accomplishment, and accomplishment leads to industry. It is a stairway of achievement having many steps. Individually many of the steps are far too high to be negotiated. Collectively the profession need fear none of them.

Today in the chemical industries we find many striking examples of widespread application of simple equipment or process, as, for example, the filter press. Many industries have borrowed this device and put it to good use. Colloid chemistry, first studied by the "pure" scientist, who thought only of its theoretical meaning and possibilities, today is being recognized as a dominating influence in many industrial fields. Innumerable other examples might be cited. However, set against these we have whole industries neglected by the chemist. Fertilizers are prepared almost without the thought of chemistry. Coking except in a very few cases is undirected by science; it remains a mechanical-engineering art, almost in fact a trade, so largely is it guided by rule-of-thumb methods. It is almost inconceivable that the chemical profession will permit these and many others to remain without the dominating influence of proper professional attention.

LABOR AND POWER PROBLEMS

Today the chemist for greatest industrial success must be something of an engineer economist. He must study labor, immigration, emigration, finance, and related problems diligently.

Much of the chemical progress will result in reducing the demand for labor in industrial processes; but simultaneously we create corresponding increase in demand for mechanical power. We thus add a need for study in the field of water power, electric power transmission, fuel prices, and related industrial requirements.

Today all industry is in competition for the supply of labor and for the supplies of fuel and power. The chemical industry cannot ignore this competition. To be sure, a young and thriving industry can usually afford to pay almost any price for essential materials or services, because the margin of profit is great; but the measure of *permanent* success will be determined by the extent to which efficient use is made of labor and by how fully the well-co-ordinated intelligent bid for power and fuel is made while directly meeting other industrial competition for these items.

The chemists working together must study these questions. They are not simple nor will they be solved in a year, nor even a decade. They will continue so long as industry continues, but ignoring them will at no time be safe.

THE NEEDED BRAINS

Individually the chemist has done much in each of the fields which has been mentioned. Collectively he has done little. Least of all has he been attentive to the problems of training up for the future of the profession the needed younger men.

Chemistry offers a romantic field for study to the youngster who may desire to consider science as a life work. More effort should be made to encourage this selection. Recently there has been some such movement, but all too little has been done along these lines. As the chemist of today goes forward in his profession, advancing from year to year in responsibility of position and size of organization directed, he will feel in-

creasingly the need for younger men to assume direction of the details of his work. Unless there is soon a strong effort made to advance the professional standards in teaching and to strengthen the college curriculum, a most distressing lack of talent will confront the executive in the not distant future. It will not be enough to have many students studying chemistry. In fact, it is doubtful whether great numbers of students in this field will be any advantage at all. Much greater effort must be made to develop the quality of work done and the standards of performance required in the chemical curriculum so that the men coming out will be the very cream of our student body. In order too that the best and most vigorous minds among the younger men will choose to go along these lines, the rosy future in opportunity for service and achievement must be clearly painted before their eyes.

Persistent advertising of a profession makes for its future success. It is perfectly proper that there should be developed a dignified sense of professional self-importance. There is nothing to criticise and everything to commend in such a policy. Of course we will find amusing results from this and some criticism will doubtless follow from time to time. Particularly striking exaggeration of this sort was spread broadcast by the much-advertised U. S. Marines quite recently. In emphasizing the opportunities of this "wonderful" service, they blazoned forth on billboards the natural steps in achievement for a young man as follows: The steam fitter becomes the steam engineer, the steam engineer the mechanical engineer, and the mechanical engineer finally achieves still higher plane as electrical engineer, who in turn may attain the highest pinnacle by a certificate of proficiency in the U. S. Marines.

We certainly do not agree that electrical engineering should be placed above mechanical engineering—rather they are on a par. Still less would we agree that a certificate of marine proficiency is the pinnacle of all achievements, but the electrical engineer working vigorously through all proper professional channels has put across the idea that electricity is the most modern of activities, and we have through this poster a reflection of the success in advancing this idea.

We wonder what will be achieved when the chemist starts a similar campaign. Certainly we may anticipate that the popular conception of today regarding the chemist will be much improved, for today the chemist varies in the popular mind from a wizard to a glorified bottle washer. Either extreme view is popular. The correct impression of his purpose and function in our modern economic life is rare indeed; and he has only himself to blame.

THE MAJOR REMEDY

There is today in the chemical profession ample vision, ample knowledge, ample energy, but all potential and undirected. The need is not greater enthusiasm; rather we require co-operation, co-ordination and concerted action. In every case the element of working together must stand foremost.

Approximately 20,000 men in this country today can properly be styled "chemist." Every year the numbers are increasing by thousands. The potential force of this group is tremendous if the group will work together. They can command attention in any field. The professional spirit, quite the equal of that to be found in our major engineering activities, will be as-

sured; and we shall have one tremendous asset which up to the present time the engineer has always lacked—that is, a single professional group.

The American Chemical Society stands today perhaps as great a scientific achievement as has been recorded by any group in any natural science. It has, however, been compelled to neglect practically all of the professional responsibilities to which the engineering bodies in the electrical, mechanical, civil and metallurgical field have given attention. It is these activities and these functions for which the need today is greatest. Individual effort or effort of small groups in individual industries will not suffice. We should not discard the tremendous asset of working altogether in a single big body, including all chemists, organic, inorganic, theoretical, industrial or otherwise. However, this group must more keenly appreciate and more vigorously prosecute these professional lines of effort.

Chemists and Chemical Engineers

On the occasion of the official inspection of the new laboratories at University College, London, Lord Moulton delivered an address on "The Training and Functions of the Chemical Engineer." In this address, as reported in *London Chemical Age*, vol. 2, p. 300, Lord Moulton said that the chemist as opposed to the chemical engineer reminded him of the difference between the mathematician and the mechanical engineer. The mathematician figured out his calculations, and his plans did not wear out. The mechanical engineer, on the other hand, worked with materials that did wear out. When the chemist became a chemical engineer he stepped from the ideal into the material world. His methods were practical, and he found himself forced to follow in the steps of the great chemists without their advantages yet bound to obtain their success. The chemical engineer worked for production on a scale that the needs of mankind demanded and he therefore abandoned the scale of the laboratory. Change of scale was more important than people imagined. It seemed very little different to work with bigger plant, and to deal with more substance than to deal with the same substance on a smaller scale. But just because it seemed not to make so great a difference change of scale was more likely to lead clever men into trouble than almost any change of conditions one could think of. Change of scale was a very difficult thing to allow for, but it was the secret of successful chemical engineering. As an illustration of the expense which change of scale involved, and the reason he put it down as the great characteristic of chemical engineering as contrasted with research chemistry, Lord Moulton said he once knew the head of a great engineering business in the North of England who prided himself on having cooked an ox whole so that it was well cooked in every part. Many people could cook a joint, but he doubted whether any of the professors of the college would undertake to cook an ox whole, and have every part well cooked. There they had the chemical engineer. This change of scale brought into the task of the chemical engineer some very difficult problems, for he had to see that everywhere the right conditions ruled. Whenever Lord Moulton had seen chemical engineering on the scale at which it had to be done to satisfy our wants, it had impressed him that things one never dreamed of as being important became serious considerations when dealing with large masses.

A Little Homily on The Brooklyn Strike

AS THESE lines are written the Borough of Brooklyn is tied up tight on account of a strike of the street railway employees. They were under agreement not to strike—and the Mayor of New York went to their meeting and took from them a pledge to withhold all action until he should have had a conference with their employers. His Honor is a comedy character whose ambition seems to be to make the laborin' man feel sure that the Mayor is with him, right or wrong, no matter what he does—as long as he belongs to some union. Unless he has a big organization with many thousand votes behind him he is not a laborin' man—down at City Hall. At 2 o'clock in the morning when the night gang left work they had another meeting of their own, and they voted to strike, despite the previous resolution at the general meeting, because somebody is said to have said, which it is admitted was not true, that a number of men had been discharged. Then those who voted against the measure at the general meeting followed the strikers out. Now chaos reigns and brickbats fly.

This speed on the trigger, this German military principle of smashing up everything and making the results as *schrecklich* as possible in order to give emphasis to an opinion, is both expensive and, in the long run, bound to be unprofitable. Now to be a street-car conductor is to engage in a respectable and honorable calling. The intellectual demands may be slight, but some of us do not respond successfully to intellectual demands, and it is well for the world that there are plenty of jobs that do not require the burden of thought. But a respectable and honorable calling does not warrant either one man or a thousand of them to throw a million people into misery and to rob them of their chance to gain a living. Surely the world is neither so stupid nor so bad as to make it necessary to paralyze a whole community every time a number of persons engaged in similar employment want something.

What we need is the application of the doctrine of relativity to life. Relativity teaches us first to consider the dimensions of ideas, and then to compute the effect of their application. That is EINSTEIN's procedure, and it is a very good one. We talk of collective bargaining, and most of us are disposed to favor the abstract idea, but isn't it time we began to think of what we mean by collective bargaining? What is bargaining? It means to negotiate beforehand; to trade. Its dimensions which we must study, in order to understand the effects of bargaining, are service, or goods, and money. Bargaining means bargaining whether done by two persons or by many. Force or compulsion does not enter into it, because, as soon as it does, bargaining ceases. If A has a house and B wants to buy it, they may bar-

gain to reach an agreement and sale, but if B knocks A on the head and threatens to keep it up until A turns over the house to him at the price he wants to pay, we cannot call it a bargain. A strike is not a part of collective bargaining; it is compulsion, and compulsion inhibits bargaining. Discharging one man or locking out a thousand is not bargaining, either. It is also compulsion.

We are in favor of rapid and effective punishment of the employer who exploits labor; who tricks the men that work for him, or even who does not recognize his great obligations to those who cast their lots with him and throw their lives and fortunes into his enterprise. We believe that every employer is in bondage to his obligations and that the man who is unfair to those who work under him should be deprived of the privilege of administering affairs that involve the employment of men and women. But we are equally convinced that the man who works with his hands by the day is also in bondage to his obligations. And if many of them form a union the union also has obligations, not only toward its members but to the general welfare. The doctrine of relativity applies here too, but we forget it in practice, and so, often, do the strike leaders. Just because we sport a union card is no reason why we should think we have privileges which are denied to others. Neither this nor the election to executive office by a board of directors will release us from our obligations.

Relativity teaches us this, and it is very sound philosophy. We need more of it; and more quantitative thinking. Whenever the Rule of Wrath begins we lose our count, and then there is the devil to pay. Should we not profit by the example of Germany?

Chemical Industries Need Government Help

MORE recognition of the domestic chemical industry on the part of the Government is being demanded. Chemists from all sections of the country are letting it be known that they feel that the Government has a real obligation to this industry, whose recent expansion has been so notable. At present there is no Government agency with an appropriation sufficient to be of material help.

There is a great deal of research as well as the gathering of information concerning industries which can be done successfully only by the Government. The general recognition of that fact has resulted in the constant upbuilding of this governmental activity until certain industries are very well served in matters where confidential information can be submitted to the Government by individuals so that all may profit by the reliable statistics which can then be compiled. In the same way the Government has taken up problems in research which are of general application. Most of these are

problems which a small concern could not afford to work out for itself.

While some chemical work is done by the Bureau of Standards and the Bureau of Chemistry, it has been for the most part along specialized lines. A large portion of the work at the Bureau of Chemistry is on food problems. At the Bureau of Standards, as the name indicates, most of the chemical work has been done with the view toward standardization. The general impression conveyed by letters reaching Washington seems to be that the chemical division of the Bureau of Mines should be expanded to take care of the chemical industry in the same way that the petroleum and mining work is conducted. As is well known, the Bureau of Mines is a part of the Interior Department, which is the great engineering branch of the Government.

The chief demand at the present time seems to be for the compilation of information concerning raw materials of the chemical industry, uses for waste products and means of obtaining greater efficiency within the industry. There is also an insistent demand for research, especially in the development of uses for byproducts which now are going to waste. Whether the Bureau of Mines could handle these investigations, except as they involve the use and conservation of minerals, is a question, yet in view of the admitted importance of an American chemical industry to America, it is reasonable to agitate for active governmental interest in its behalf.

Future Lines of Progress in Steel

THE steel industry still finds itself in the position it has occupied since it came into being: in need of making expensive improvements. There is always something more to be done. The steel manufacturer never gets to the position of feeling himself "on Easy Street" with nothing to do but operate his plant as it stands and make the money.

Building of byproduct coke ovens has had a wonderful vogue, as such things go, but with all the additions to coke-making capacity the market for Connellsville furnace coke for two months past has averaged about \$18 per net ton at ovens. Those who held back from building byproduct ovens thinking that what others were doing would make beehive coke cheap have been completely disappointed. There is more money than ever in byproduct operations, and those who have byproduct ovens have occasion to carry farther their operations of winning byproducts.

The course of the pig iron market has shown that a steel works is not safe in depending upon the market for supplies. When, years ago, the major part of the merchant pig iron made was used in making rolled steel, the steel industry made the pig iron market. Now the pig iron market is made by the foundries, chiefly the gray iron and malleable foundries, but a considerable part of the bessemer and basic iron made for sale is taken by steel foundries. The remaining works making rolled steel will in most cases find it desirable to build their missing blast furnaces.

As a very large consumer of fuel the steel industry has had forced upon it the fact that it must go in for much greater fuel economy in future, for while coal will decline from the particularly exorbitant prices lately ruling, it will never be relatively as cheap as

it was before the war. In addition there is the changed outlook regarding supplies of oil, which the steel industry can hardly count upon as it recently thought it could.

In the matter of introducing labor-saving machinery and devices the steel industry has as much before it as at any time in the past, for high wage rates have come to stay and in addition there is within the discernible future the elimination of the 12-hr. day, which means that in some cases a given improvement will save the work of three men in the twenty-four hours instead of the work of two.

The steel industry has only begun to make special steels. The demand for special steels, suited to the particular purpose, has grown while it slept. For a year past there has been a "sellers' market" in steel and the buyer hesitated to express his new-found wants, being glad to accept almost any kind of steel, but no such condition can last indefinitely.

Possibly in the quality competition that is to come the steel industry will go considerably farther in the matter of vertical integration, carrying its products to a greater degree of finish. Hitherto there has been a strong disposition on the part of steel manufacturers to stop with the ordinary rolled products, carrying vertical integration backward to the minerals in the ground rather than forward into the manufactured wares, but it seems rather unscientific for rolled steel producers to sell large annual tonnages to single consumers, who in turn have but few customers and whose operations are more or less simply forming operations, when success depends as much upon the character of the steel purchased as upon the skill with which the relatively elementary forming operations are conducted.

Whether the steel industry will become more scientific in marketing its wares remains to be seen. It has the much criticised "open contract," but it has been running as full as it could up to date, while the woolen mills, which have the "binding contract," have been largely closed. One cannot predict what the steel market will do, when this year it has exhibited a phenomenon no one would have believed possible, that of about 45 per cent of the production being sold at a set of stabilized prices now seventeen months old, while the rest has been sold practically at what it would bring.

Chairman Bancroft's Report To the National Research Council

WHENEVER Professor WILDER D. BANCROFT writes or says anything it is worth reading or hearing. He has been for the past year Chairman of the Division of Chemistry of the National Research Council, and his annual report of the Division was published in the September number of the *Journal of Industrial and Engineering Chemistry*. The restriction of the chairmanship to a single year's incumbency was designed to provide for the incidence of the greatest variety of tried and experienced directing minds upon chemical research. Instead of systematizing the organization until it runs itself while everybody does routine work, the very opposite is provided for, and this is as it should be. It is easy to kill research with too much system, although in selecting Dr. BANCROFT for the post all possibility of dullness was avoided. He is a man of infinite variety, who couples with this engaging quality the accomplishment of profound scholarship and the habit of thoroughness. As for the work done, he refers

to the reports of the chairmen of the various committees which have already been published. He then proceeds to indicate questions that need answer.

An interesting point which he brings out is the work which is needed and called for along the borderland between chemistry and one or more other sciences. "The conditions at Washington," he says, "are peculiarly favorable for such a development, because the chairmen of the different divisions are under the same roof and can discuss matters informally in the most satisfactory manner. It is easy to see that if we bring together, for instance, men representing three different sciences involved and if each man knows a quarter of a given problem, then the problem is three-quarters solved before any further work is done." And he proceeds to note some of the borderland problems which interest him.

In baking, the American Institute has recently been founded with Dr. H. E. BARNARD in charge and Dr. MORRISON to direct research. The Advisory Board consists of Messrs. BANCROFT, BARNARD, CLOWES, HENDERSON, MCCLURG, MCCOLLUM, MENDEL, MENDENHALL, MORRISON, MARLIN, PRESCOTT and TAYLOR. We congratulate the Institute of Baking on such a distinguished and capable selection of advisers. One of the unanswered problems has to do with the nature of gluten. A high gluten content seems to provide generally for superior bread, but the rule has too many exceptions. Bakers refer to "strong" and "weak" glutes, and yet the different glutes appear to have the same chemical composition. It is not known whether the differences are due to structure or to the presence of salts. Staleness seems due to a displacement in the distribution of the water content between the gluten and the starch. To prevent this is another problem in colloid chemistry. Again, why is home-made bread better than baker's bread? Why is French bread better than American bread and Vienna bread better than the French? Thus far the microscope does not appear to have been used in the study of bread. What will it tell?

The problem of stimulating pine trees to give a better yield of turpentine is discussed at length, the work of TSCHIRCH, HERTY and Miss GERRY is considered with a view to getting more light—and more terps and gum. The plan involves the study of a botanist, a microscopist, an organic chemist and a colloid chemist. Then he proposes the application of similar research to the collection of rubber, and finally to shellac.

The study of protoplasm is recommended in connection with the study of emulsions, and the further study of war gas problems is important in that it opens the way to the study of the chemistry of blisters and burns and also leads up to the important general subject of chemotherapy, which calls for joint research by medical men, biologists and chemists.

Other investigations recommended have to do with special sugars, with the normal weight of men and the search for whatever the regulator may be which determines and controls his normal weight, structural colors, sedimentary rocks—just as the Geophysical Laboratory studies igneous rocks—clay, pressure phenomena within the earth, thunderstorms, surface colors, Brownian movements, adsorption of gases, criteria of purity, quicksands, metallic luster, and educational tests.

Dr. BANCROFT says that the Division is still "long on promises and short on results," and he mentions it

apparently with regret. We hope on the other hand that its aspirations will always be greater than anything that is or even can be achieved. This is only possible when men of inspiration lead it.

Pyrolytic Distillation and Pyrogenesis of Hydrocarbons

NOW is the time to choose between the terms "pyrolytic distillation" and "pyrogenesis of hydrocarbons." If one expression is not wide enough in scope for technical purposes, both should be used after precise definitions have been established. W. A. HAMOR, co-author with Dr. BACON of the best treatise on petroleum, is sponsor for "pyrolytic." Etymologically it is a gem. It will make a good team mate for its brother adjective electrolytic, while pyrolysis can associate with electrolysis among the nouns. The second term was put into use in England after BERTHELOT demonstrated the fact that acetylene could be polymerized into liquid hydrocarbons under heat and pressure. That our so-called petroleum cracking process does not come under this class of reactions is amply demonstrated elsewhere in this issue by Mr. PADGETT. In our opinion pyrogenesis should be limited to cases when the benzenoid hydrocarbons are produced.

At a future and probably not distant date we shall hear of pyrochemists. The chemical phenomena of heat well merit special training on a similar basis with electrochemistry. Demands for such training now exist in the petroleum industry and are being met about as satisfactorily as were the unanswered calls for electrochemists voiced by DAY at Niagara sixty years ago.

Cook's Tours à la Mining Engineers

WHEN a technical society—or rather a few fortunate members—go touring, as recently did the Mining and Metallurgical Engineers, they usually return with at least two uniform impressions. One is that they have been spending several days with some very fine people, getting acquainted as would otherwise require years in our modern cities, and the other is that they need quantities of rest and quiet after the exhausting hospitality tendered by the various hosts en route.

Indeed, if the trippers realized what was before them when they start as well as they know what happened to them after it is all over, they could easily be organized into a temporary union with a principal "demand" for a 12-hour day (maximum). Anyone who crawls into a berth at midnight after attending a banquet, only to travel 200 miles and be awakened by the porter at 6:15 the next morning so as to have breakfast and be ready for another 15- or 16-hour "shift" starting at 8 o'clock, has reason to exclaim with the poet, "A truce to so much hospitality!"

Doubtless, though, unionization will fail. We shall have to put ourselves unreservedly in the hands of our friends. But at the same time we hereby serve notice upon the Secretary of the Institute that he will be held personally responsible for arranging it in the future so that in case one day ends in a midnight "athletic contest" the next day may not start before noon! Or, if the next day's hosts insist upon a 10 o'clock start, to demand an earlier athletic contest—for we certainly can't miss anything so exciting!

HUDSON RIVER MILL OF THE INTERNATIONAL PAPER CO.

Fall Meeting of T.A.P.P.I. at Saratoga

Résumé of Special Papers Presented at the Meeting of the Technical Association of the Pulp and Paper Industry—Visits to the Paper and Pulp Mills and Other Plants Allied to the Paper Industry—Social Features—Abstracts of Speeches

THE fall meeting of the Technical Association of the Pulp and Paper Industry was held at Saratoga Springs, N. Y., Sept. 1 to 3 inclusive. The meeting was called to order in the Casino by Chairman Raymond S. Hatch, who after a few introductory remarks introduced the first speaker, Edward B. Ashton, chairman of the Chamber of Commerce. Mr. Ashton greeted the members of the association heartily and welcomed them to the hospitality of the city.

George S. Witham, Sr., manager of mills of the Union Bag & Paper Corporation, replying in behalf of the society, emphasized the appropriateness in the choice of Saratoga for such a gathering, as it was located in the heart of the Adirondacks, replete with the history of paper making. He also spoke in the highest terms of our neighbors on the north who are closely allied with us in the paper industry and who have lived for so many years in close proximity without even so much as a single modern fortification on the whole borderline. Mr. Witham also commented on the lack of foresight on the part of American paper manufacturers in the past in their wasteful manner of lumbering, and strenuously urged the necessity of concerted action in the future to conserve our present timber supply if the paper industry in this country is to remain independent of outside sources.

Improvements in the paper industry due to the application of chemical and engineering technology, and the contribution and importance of paper in the dissemination of knowledge and advancement of education were also brought out.

For the executive committee, Chairman Raymond S. Hatch reported a steady increase of membership since

the annual meeting held in New York four months ago, the total membership now exceeding 602. Two members had been lost by death, George C. Sherman and Henry Earl Surface.

It was stated in the report that after long and careful deliberation the executive committee had decided to abandon the idea of publishing a trade journal through the Tappi Publishing Corporation. Instead of this the association is to undertake the publication at least semi-annually of a volume of proceedings, transactions, abstracts of literature and original articles. The committee said that a beginning has been made by the publication of a revised edition of the paper testing committee's report. The work bears the title "Paper Testing Methods," and constitutes a practical treatise on approved modern methods for testing papers by microscopical, chemical and physical means. The work is illustrated and one of the chapters deals with the fibers used or proposed for use in papermaking.

The committee recommended an increase in the annual dues of members and associate members to \$25, the subscription for juniors being allowed to remain at \$5 as at present. As this necessitates an amendment to the constitution and bylaws, unanimous consent was asked and granted for a suspension of the rules. The amendment was adopted by unanimous vote.

In conclusion the executive committee expressed hearty appreciation and thanks in behalf of the association to the paper manufacturers of the Hudson River and associated industries for the splendid entertainment and educational features which had been provided for the fall meeting.

After various committee reports the remainder of

the first day was devoted to the reading and discussion of the technical papers.

R. E. Lofton and M. F. Merritt of the Bureau of Standards, Washington, gave an interesting paper on a quick method of determining the presence of sulphite fiber in pulp. This method depends upon the selective action of certain dyes for sulphate and sulphite fibers.

NEW FELT-CLEANING DEVICE

In a paper on "New Felt-Cleaning Device" C. A. Woodstock discussed a new device for cleaning the felts of paper machines without the necessity of shutting down the machine.

This suction effect is adjustable, and can be applied to the felt, which has previously been treated with water or some other cleansing solution to loosen any included material, and clean it without interfering with the operation of the machine. This saves considerable time, effects a large saving in cost and increases the production greatly.

The results in economy on three Fourdrinier paper machines running on newsprint at a speed of 650 to 675 ft. per minute were an increase of production of

vapor is condensed in a surface condenser under a vacuum. In condensing it gives up its heat of condensation to the cooling water, which now becomes hot enough to act as a source of heat energy in an ordinary steam boiler. This steam drives a steam turbine. Great care must be taken to have all mercury lines and joints perfectly tight, as mercury is very poisonous, especially in the vaporous state.

According to *Power*, Mr. Emmet claims that by the addition of this device to an assumed good modern power station, with an increase of 15 per cent in the amount of fuel used, the same amount of steam can be supplied to the steam turbine as under present conditions, and the mercury turbine will generate power equal to about 66 per cent of the power generated by the steam turbine. This results in a gain in station capacity of approximately 66 per cent with an increase of only 15 per cent in the amount of fuel required.

CURTAILING BLEACH CONSUMPTION BY ADDING SULPHUR TO DIGESTER LIQUOR

George K. Spence gave a summary of the results of his experiments on the effect of added sulphur to digester liquor on curtailing bleach consumption. Since it requires 11 lb. of sulphur per 100 lb. of stock to save 92 lb. of 35 per cent bleaching powder there would be very little advantage in its use under ordinary conditions. However, it is claimed that increased strength is produced by its use in the digester liquor, which will furnish material for further experiments in order to determine the extent of this increase.

AUTOMATIC CONTINUOUS MIXING SYSTEM

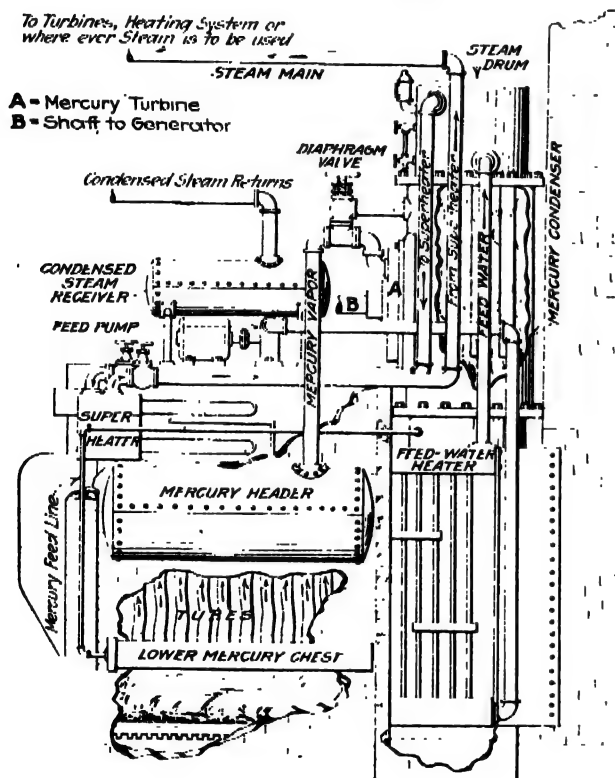

A new automatic method of handling paper stock so as to economize on floor space, labor and power was presented by E. J. Trimbey.

Ground wood and sulphite are furnished continuously, either by gravity or by pumping to their respective compartments of a double vat. Each compartment is provided with an overflow dam and a float valve of special design for maintaining a constant level in the compartment regardless of the rate of flow of stock. Mounted in one end of this double vat is an outlet spout communicating with both the ground wood and the sulphite compartments, and so arranged with a separating partition and an adjustable top that the cross-sectional areas for the outflow of ground wood and sulphite will give the desired proportion of each, and at the same time the total flow can be varied to meet the changing requirements of the paper machines.

In addition to being adjustable for both total volume of flow and relative proportions of ground wood and sulphite, the outlet spout has valuable regulating features which automatically compensate for minor variations in the consistency of each. With a constant head and varying velocity and consistency, a proper design of apparatus can be made whereby the increase in velocity of the paper stock flowing through it can be made to counterbalance the increase in consistency, so that within a given consistency range there will be a constant rate of discharge of dry stock per unit of time.

C. A. Allen read a paper on the Automatic Cooking Control for Sulphite Digesters, which will appear in a subsequent issue.

H. P. Baker, secretary of the American Pulp and Paper Association, as toastmaster at the T.A.P.P.I. ban-

SKETCH OF EMMET MERCURY BOILER

12½ per cent, increase of speed 7½ per cent and an increase of efficiency of 5½ per cent.

BOILER ROOM EFFICIENCY INCREASED BY A NEW MERCURY BOILER

Probably the most interesting subject discussed was the mercury boiler designed and described by W. L. R. Emmet of the General Electric Co.

In this device Mr. Emmet has made use of the physical properties of mercury to increase the boiler efficiency. He has designed a mercury boiler in which mercury vapor under a pressure of 10 lb. is first used to drive a mercury turbine and the exhaust mercury

quet, spoke of the part chance had played in the past in the paper industry and how the association was fast doing away with chance and substituting facts in its place. He also emphasized the greater need for a broader knowledge of the paper industry as a whole among the general public.

Other speakers were L. H. Shipman, of the Spanish River Pulp & Paper Co. and chairman of the technical section of the Canadian Pulp and Paper Association, and George Sisson, Jr., president of the American Pulp and Paper Association. Mr. Sisson complimented the members of T.A.P.P.I. on their efficient service and spoke of the spirit of modern business, emphasizing the spirit of co-operation and the tendency to get together to solve the common problems. He also spoke of the ever-increasing demand for paper and of the untold value of research to the industry.

VISITS TO PLANTS

Thursday was devoted to visiting the various paper mills located in the immediate vicinity. Automobiles took the members to the Hudson River Mill of the International Paper Co. at Corinth and the Finch Pruyn Co.'s plant at Glens Falls, where the members, divided into small groups, were conducted by guides through the mills.

HUDSON RIVER MILL

This plant is situated on a water site which gives an 84-ft. head which is used in two stages to develop approximately 20,000 hp. In addition the plant is equipped with five 520 B & W boilers equipped with Coxe stokers for handling fine anthracite. In the paper mill there are Curtis mixing tanks, nine news and one wrapper machine. The wood room has one Paulson drum, six Portland drums of twenty-five cords per hour capacity. Ground wood mills have fifty-six grinders, six improved first screens, twelve flat second screens, twenty-two deckers and twenty-eight presses. The shredding system consists of Jeffrey shredder, Mitts & Merrill shredder and three Allen mixers. There was stored in the yard for use during low water 22,000 tons of lap ground wood pulp. The pulp is carried into the mill by a belt conveyor, which drops it into a Jeffrey shredder, whence it is taken away by another conveyor to the Allen mixing system. The daily production of the mill is 275 tons news, 12 tons mill wrapper, 60 tons sulphite and 320 tons ground wood.

FINCH PRUYN Co.'S MILL

This plant, located at Glens Falls, N. Y., is a ground wood and newspaper mill. It has a total water-power development of 15,000 hp., the rating of the grinder wheels at an average head of 39 ft. being 12,000 hp. There are twenty-five 27 to 32 x 54-in. grinders, which have a maximum production of 200 tons in twenty-four hours. Production for 1919 was 32,061 tons. Grinding is done by the Hall's process method. Tailings run under 2 per cent. The mills make newsprint and hanging. There are three Fourdrinier machines, one 90 in., one 116 in. and one 148 in. with 70 ft. wires; three presses and thirty-two 34 to 48-in. diameter driers. These machines run at speeds of 650 to 675 ft. per minute and at present average of standard newsprint is 775 to 790 lb. per day per inch trim. Average for July was 784 lb. All machines are equipped with Woodcock & Walker felt-cleaning system.

VISIT TO PAPER MACHINERY MANUFACTURING PLANT

A short recess for luncheon as guests of the Hudson Valley Manufacturers at the Glens Falls parish house was followed by a trip through the Sandy Hill Iron & Brass Works, where the members had an excellent opportunity to see the paper machines and screens in the process of manufacture.

UNION BAG & PAPER CO.

A plant capable of turning out 14,000,000 bags and sacks daily next took the attention of the visiting members. This factory contains thirty-four printing presses and complete equipment for composing, stereotyping, etc. All printing is done from stereotypes, no original type being used. There are twelve rotary suction presses with automatic feed and counting attachments printing in one and two colors; fourteen platen or hand-feed presses and eight rotary web presses for printing bags in rolls. Total capacity, 1,750,000 impressions daily.

The machine room of the factory contains forty-five machines, all of which make square and flat or old-style grocery bags. The smallest of these machines, making 1-lb. and 1/2-lb. bags, will turn out as many as 225,000 bags per day.

In the finishing department the bags were tied in packages of 500 each and wrapped in bundles of heavy kraft paper for shipping. The largest machine room had eighty machines, all making the automatic or self-opening style of grocery bag in sizes from 1/2-lb. to 35-lb. The last room visited was equipped with fifteen machines for making various sizes and weights of sacks for flour, charcoal, poultry lime, fertilizers, etc.

Across the river stands the big Fenimore pulp and paper mill of the company. This plant uses the sulphite process and is a model of neatness. The logs are floated to the chipper and the chips carried by belt conveyors to the four digesters, which have a capacity of twenty-five cords each, when they are cooked for seven to eight hours. The pulp from the digesters is then pumped to the mixers and screens to be made into paper.

A three-hour delightful sail on the beautiful Lake George, where the guests were entertained with a concert given by the Union Paper & Bag Corp. band, followed by a luncheon, completed the second day.

MEMBERS VISIT G. E. PLANT AT SCHENECTADY AND FELT PLANTS AT ALBANY

Wednesday was devoted to visiting the General Electric Co.'s plant where the society was conducted in small parties through the mammoth plant. Special interest centered in the new mercury boiler and in electrical machinery designed for the paper industry. After a luncheon in the dining hall, at which General Manager Erben welcomed the visitors, the rest of the day was consumed in visiting the felt plants of F. C. Huyck & Sons and the Albany Felt Co. In these plants the process of manufacture of felts for Fourdrinier machines was shown from the raw wool to the finished product.

About 350 of the 600 members attended the convention, which was the largest and most successful gathering yet held. It was with a feeling of great satisfaction for the results accomplished and gratitude to the officials of the various paper companies for their generosity and cordial hospitality that the meeting closed.

The Separation of Air Into Oxygen and Nitrogen

Use of Oxygen in Chemical and Metallurgical Processes Retarded by Inefficiency of Existing Systems for Air Separation—Power Requirements for Theoretical and Existing Systems—Liquefaction of Simple Gases—Condensation and Distillation of Mixed Gases—Improved System for Air Separation

By FRED E. NORTON

THE industrial use of oxygen gas for welding and cutting has been developed almost entirely through a distribution system involving the use of steel bottles as containers for the highly compressed oxygen. On the other hand, the fixed nitrogen industry demands that the nitrogen be produced immediately at the fixation plant, and hence the separation process becomes a part of the fixation system, because of the enormous volumes of gas to be handled.

RESTRICTIONS OF PRESENT PROCESS

It is evident that if oxygen is to be used for large chemical or metallurgical processes, it will be necessary to install the air separation plant adjacent to the point of application of the oxygen. It is out of the question to expect that bottles or other containers can be used where such immense masses of oxygen have to be considered. Where bottles are employed the charges for interest, demurrage and handling so far exceed the present plant cost of the oxygen that the latter item is almost negligible, and hence the manufacturers are not greatly concerned about the plant cost of oxygen, since it is not a deciding factor in respect to sales. Oxygen is demanded, and the sales price is many times the plant cost. The purchaser's interest need not be considered in this respect.

The case is far different if oxygen in bulk is in question. The development of the application of oxygen in many chemical as well as metallurgical problems is now reduced to the simple one of cost. There is no question as to the desirability or feasibility of applying oxygen to oxidation processes in general, such as the burning of sulphur, the oxidation of ammonia to nitric acid, all smelting operations, and the manufacture of water gas.

FEASIBLE COSTS

The industrial applications of oxygen depend very largely on the cost of the oxygen.

A fair estimate may be made of the value of the oxygen by considering the cost of burning one ton of carbon to CO, or to CO₂.

For high-temperature work, such as iron blast furnaces, the bulk of the coke is burned to CO only.

Taking a base cost of oxygen at 1c. per thousand (16 lb. of oxygen per 12 lb. carbon), we have 33.63c. for the oxygen to burn one ton of carbon (2,240 lb.) to CO, say 34c. If the combustion is complete, the cost would be (32 lb. oxygen per 12 lb. carbon) 67.26c. to burn one ton of carbon to CO₂, say 68c.

It is estimated that for a production of, say, 4,000 cu.ft. of oxygen per minute the cost of oxygen may be reduced to, say, 6c. per thousand (including all fixed and daily charges).

The cost of blowing a smelting furnace with pure oxygen would, therefore, amount to $0.34 \times 6 = \$2.04$

per ton of carbon burned. However, it would probably be advisable to use a blast of, say, 35 per cent O + 65 per cent N of which half the oxygen would come from air to be mixed with the oxygen blast. We may, therefore, estimate that the oxygen blown to the furnace would come equally from normal air without cost, and from a separation plant, at, say, 6c. per thousand, or, say, average cost 3c. It would, therefore, cost $3 \times 0.34 = \$1.02$ for the oxygen to burn one ton of carbon to CO or, say, \$2 to burn one ton of carbon to CO₂. These figures are easily seen to be within reason, and include all interest and depreciation charges.

For smaller plants, the cost would rise, and on the scale of existing plants, a cost of perhaps 25c. per thousand would be reached. This is because of the heavy ratio of plant charges for small capacities, and also because in any thermal process the loss per cent diminishes rapidly as the size increases. However, the new system has the advantage in all except the laboratory sizes. It may be said that the advantage increases rapidly with the capacity of the plant, and there is no limit as to size in sight.

A cost of 25c. per thousand for oxygen means \$8.50 for the combustion to CO, or \$17 for complete combustion (per ton of carbon with pure oxygen). These figures would be halved in the case of 35 per cent O + 65 per cent N mixed blast.

The present indications are that 25c. per thousand is about the limiting cost. For ultimate economy 65 per cent nitrogen is too high.

NEW FIELDS OPENED

Returning to 6c. basis for oxygen. What an enormous field lies open before oxygen at such a cost! The smelting of manganese and chrome, as well as high silicon and carbon irons, is most directly affected. With control of the oxygen content of the blast, and much higher temperature (and available heat), come an approach to electric furnace conditions, without excessive cost.

The possibility of making steel direct from the ore is not to be disregarded. In this connection, a whole new field lies open in the making of carbides by direct heat in an oxygen-blown furnace and in the treatment of these carbides with nitrogen.

The whole nitrogen-fixation industry may very possibly depend on the cheap production of carbides by oxygen-blown furnaces, independent of cheap power, or pure materials of extraordinary cost; and in unfavorable localities. The disintegration of such slags by gas blast instead of by grinding is an incident to this development worth consideration. The developments may take many years, but they cannot begin until a cheaper source of oxygen is available, and this first step is assured in the immediate future, the technical basis being completely solved.

Turning to the applications which are already well developed, the welding of large masses of metal is hampered by the necessity of using acetylene gas to *save oxygen*, and the reduction in the cost of oxygen will permit the use of cheaper *gas*. It may be expected that even the acetylene will be indirectly cheapened by the more economical production of carbide by oxygen-blown furnaces. The welding of tubes and large structural parts thus assumes a new aspect as to cost.

In the matter of gas manufacture, there is the possibility of driving a water-gas producer continuously. A producer may be fed with raw coal, and if oxygen and steam be mixed in the proper proportions, a continuous partial combustion of the carbon to CO (with a small per cent of CO₂) will keep the remainder of the fuel at a high enough temperature to decompose the steam into hydrogen, and the oxygen thus released will combine with the incandescent carbon to furnish CO. With such a producer, a high quality of gas may be made, quite suitable for use in stoves and incandescent mantles. In view of the rising cost of city gas, this is a most economic advance. It is easy to calculate the approximate cost of gas making, and even if the base cost of oxygen be doubled or tripled, a very great saving is inevitable.

The smelting of all volatile metals, such as zinc, is an obvious application, and many uses of cheap oxygen will appear in this field.

In the manufacture of sulphuric acid, nitric acid, ammonia, and in fact the whole of the chemical industry, oxygen is the live element which carries all else with it. There is no need to multiply the examples of useful application, but there is great need of a better understanding that the cheap oxygen is within reach and that plans for the immediate future should consider this fact.

EXISTING SYSTEMS INEFFICIENT

The costs stated are so far removed from any possibility with the present systems that it may appear that some error may exist in the estimates. The very fact that such costs are possible changes the whole status of the oxygen industry, and makes it difficult for those closely engaged in the oxygen business to credit the figures. It can only be said that the estimates have been very carefully made by means of accurate data, and that the basis of the liquefaction system is one which has a theoretical efficiency of unity.

On the other hand, the existing systems, to which comparisons will unavoidably be made, have a basic efficiency of less than 10 per cent. The demonstration of this fact is not complicated—it is so extremely simple that one is unwilling to accept the evidence of plain facts, because the existing systems give unavoidable prejudice. If the waste of power is kept in mind the whole will be clear.

It is evident that if the very low efficiency of existing systems is due to a mistake in the choice of physical conditions the probability of error of judgment lies heavily on the advocates of such defective systems. It is not to be expected that enthusiastic indorsement will be given to a clear proof of the mistake in fundamental physical conditions which are essential to high efficiency. Unavoidably, the exposition may appear to reflect unfavorably on the judgment as to what may afterward appear to be obvious facts. We wish to emphasize the fact that there is a fundamental error in the separation cycles as developed along the lines of the

old processes, and that these processes cannot be improved by "doctoring" them here and there. The basic defects are:

First, the total destruction of the primary work of compression. This is not a necessary requirement of nature, and results from bad thermodynamics.

Second, a false step in the distillation of the air—i.e., the introduction of outside heat into the still.

RADICAL CHANGE REQUIRED IN EXISTING PROCESSES

These matters are of extreme simplicity in themselves—they will be demonstrated in another place. Our object now is to point out that the present estimates are based on new developments, and the figures for cost must not be considered as arising out of trivial modifications of existing processes. We admit at once that no existing system can produce oxygen at a cost which will permit of commercial use in metallurgical processes. By the application of proper thermodynamic steps (which are radical) the existing apparatus can be made to give costs approaching our estimates. The systems would then be distinctly new and have been thoroughly protected by broad patents.

DEVELOPMENT PROSPECTS

In view of the wide application of the process, it has been determined to keep it free from exclusive control and yet to preserve the incentive of sufficient control to encourage development in as many lines as possible. No operating system has been constructed, and it will be realized that since high economy may only be reached with a large plant, it is a serious financial undertaking. The history of such developments in the United States is not encouraging. The telephone, telegraph, electric light and air brake are typical of purely American ventures requiring small capital in the beginning and large and steady returns from the first. The exception of the Atlantic cable is remarkable. The railroad, steamship, deep mining, steel making, the gas and oil engine, the airplane, the aniline dye industry, the nitrogen-fixation industry and even the automobile and so many other developments are typical of European enterprise, in the middle stage of developments, if not in the earliest period. So many of these developments originated in this country and languished here for want of capital that there is ample ground, on precedent, for fear of a repetition of history in this new oxygen field. There is not an immediate possibility of great gain, in money, without investment of large sums for plant and development work. The prospect is not enticing from the stock-market point of view.

RETARDED DEVELOPMENT

While the development of oxygen production on a large scale is undoubtedly an expensive matter, the immense field which lies undeveloped constitutes perhaps the most evident attraction in sight for the adventurous and progressive pioneer in chemical and metallurgical enterprises. Granting that if oxygen be cheap enough, there are numerous applications, it may seem strange that so little has been accomplished in the direction of lower costs for the oxygen.

The situation is not a creditable one to American industry. Our path has been strictly in the footsteps of German and French pioneers, and no independent thought seems to be evident in the design or construction of air separation plants in this country. The

reasons for this conservatism are perhaps good, for apparent commercial reasons; but it is believed that it can be shown that the reluctance to strike along original lines is owing to an imperfect understanding of the real problems and not the nature of the problem itself.

It is a strange fact that the oxygen business today is practically a monopoly, though air is free to all, so the business has the great attraction that nature furnishes the raw material free-of cost. Perhaps this fact has hindered development, since cheap raw materials often lead to crude methods. The secrecy which has been maintained for so long seems to be equally based on ignorance and timidity on the part of the commercial element in the oxygen business. The purpose of this article will, therefore, be to clear up such of these obscurities as may lead to at least an elementary idea of the possibility of advance in the direction of lower costs of oxygen and nitrogen and hence in the development of industries which have unbounded prospects of economic advance.

OBVIOUS DIFFICULTIES IN AIR LIQUEFACTION

In the first place, the idea that the extreme cold required to liquefy air in a counter-current system (and this is always a preliminary to the separation into oxygen and nitrogen) is a difficult and dangerous state to reach is false. This idea has been cultivated and imaginary obstacles to air liquefaction have been multiplied by those interested in the protection of existing monopolies. It is a perfectly easy matter to liquefy pure, dry air, and no unusual precautions are needed to do it with standard commercial compressors and a little copper pipe. The use of steel instead of copper apparatus is perfectly feasible, and high pressures are not essential.

The one vital preliminary, however, is always that the water vapor and carbon dioxide in the ordinary air must be absolutely removed, and it may be said that 90 per cent of the problem is solved, so far as the operation of an air system is concerned, when this has been perfectly accomplished.

Without going into details, it may be said that the preliminary freezing of the air down to, say, -100°C . will remove sufficient of the water vapor to permit continuous running of the separation system without clogging or coating of the heat transfer system. By means of pre-coolers, in duplicate, and so arranged that the units are alternately cooled and thawed, the moisture removal is a demonstrated success. This problem is solved. The CO_2 removal may or may not be required, since its ice forms an emulsion in liquid air which does not interfere with an apparatus which is free from restricted passages or small pin-hole throttles. However, it may be cheaply removed by preliminary washing with weak soda or lime solutions in mechanical washers. This difficulty is serious for some types of apparatus, but trouble may be avoided either by the chemical removal of the CO_2 or by a change in the design of apparatus.

The system to be described has no restricted passages and no throttles or other mechanisms which may become clogged with water or CO_2 ice. This is perhaps the most important practical element in the whole problem.

It should be emphatically stated that clean, dry air is easy to separate. Ordinary moist air cannot be liquefied continuously, because of obstructions in the apparatus. It should also be stated that there are many

other unsuspected things (solid and gaseous) in ordinary air; and provision must be made to get rid of them, or explosion and choking will occur. These are easily provided for and are matters of good design. It is in respect to such apparently trivial things that great advance is possible in the practical operation of air separation systems. Owing to the past history of the development, it is quite probable that the existing methods do not form a good basis for estimating the possibilities of improvement.

While the existing methods of air purification are crude and unsatisfactory, they are not so vitally defective as the liquefaction and separation cycles which have so far been used. It is not too much to say that this defect is so little understood, even by those familiar with the existing systems, that the argument may fall on ears deaf to the facts, because no sound basis is available to evaluate the real situation. These rather harsh statements are justified by the claims, so often made, that the existing systems do not fall far short of theoretical efficiency.

ELEMENTS OF COST

Let us see what the separation of air by liquefaction demands in respect to total cost.

First—Interest and depreciation of plant.

Second—Cost of labor.

Third—Purification.

Fourth—Power.

The first item will depend on the effectiveness of the apparatus—i.e., on per cent oxygen recovered out of the total in the air which enters the apparatus. In a minor degree, it is affected by the efficiency—i.e., the ratio of power used to theoretical power required; since the cost of machinery, such as motors, etc., will depend on the wasted power. However, this item may be set aside, since it will be shown to follow, as a consequence of the proposed improvements, that the first cost of plant will be reduced as compared with existing systems. It is not the controlling variable, though a very large element of cost of oxygen.

The second item, labor, may be set aside as practically the same for all systems.

The third item is of utmost importance, as it affects continuity of operation, and hence the production factor of a given investment. It may be reduced to a point of minor importance, as will be shown.

The fourth item is the critical one, and it is here that all existing systems fail in basic principle to realize in any way the moderate demands imposed by nature as the true cost of air separation. It is very easy to evaluate the power requirements of any existing system.

THEORETICAL POWER FOR SEPARATION OF AIR

The separation of 1 kg. of air into oxygen and nitrogen demands simply the isothermal compression of about 0.23 kg. oxygen from 0.2 atm. to 1 atm., and a similar compression 0.77 kg. nitrogen from 0.8 atm. to 1 atm. That is, the two components, oxygen and nitrogen, must be compressed isothermally at atmospheric temperature from their individual partial pressures in the atmosphere to the total pressure of 1 atm. on pure separated gases. And however much the fact may be disguised by complicated stills and interchangers, it is only this effect which the whole must, in theory, produce.

We may take 300°C . abs. (27°C . or 80°C .)

F.) as the temperature of the atmosphere, while the gas will be measured at zero deg. C.

$$\begin{aligned} \text{Hence } W_n &= 0.77 \times 0.163 \times 300 \log 1.25 \\ &= 3.649 \text{ cal. per } 0.77 \text{ kg.} \\ &\quad \text{nitrogen} \end{aligned}$$

$$\begin{aligned} W_o &= 0.23 \times 0.1423 \times 300 \log 5 \\ &= 6.896 \text{ cal. per } 0.23 \text{ kg.} \\ &\quad \text{oxygen} \\ &10.545 \text{ cal. per kg. air} \end{aligned}$$

This amounts to $10.545 \div 10.69$, or, say, 1 hp. per kg. of air separated per minute.

Since 1 kg. air has a volume of 0.7734 cu.m. at zero C. we have $1 \div 0.7734 = 1.2931$ hp. per cu.m. air separated per min. giving 0.21 cu.m. oxygen or, say, $1.293 \div (60 \times 0.21) = 0.103$ hp. per cu.m. oxygen per hr. (2.92 hp. per 1,000 cu.ft. oxygen per hr.)

For all practical purposes, we may take 0.1 hp. per cu.m. oxygen as the theoretical power required for separation (per hr.).

Now, existing systems may produce oxygen when the air is compressed to, say, 30 atm. (435 gage). The compression of 1 kg. air to 30 atm. at 300 deg. C. abs. (27 deg. C.) requires (adiabatic 2 stage) $W_A = 2 \times 0.236 \times 300 (30^{0.28} - 1) = 90.2$ cal. per kg. air, or $90.2 \times 1.293 = 116.6$ cal. per cu.m. air.

Since about 5 cu.m. of air is required to contain 1 cu.m. oxygen, and existing processes must compress, say, one-third more air than is separated, we have $116.6 \times 5 \times 1.333 = 777$ cal. per cu.m. oxygen delivered pure, or, say, $777 \div 10.69 = 72.7$ hp. per cu.m. oxygen per min. Therefore, such a plant would require $72.7 \div 60 = 1.21$ hp. per cu.m. oxygen per hr. (34.27 hp. per 1,000 cu.ft. oxygen per hr.). The efficiency would be $0.103 \div 1.21 = 0.085$, or 8.5 per cent, and surely this is not a very creditable figure for a process which may be shown to be reversible in theory.

EXISTING SYSTEMS

There are two systems in use for separating air by liquefaction and distillation.

One of these depends on the cooling effect produced by the simple expansion of very highly compressed, imperfect gas. A simple nozzle may be used, and a small cooling effect may be realized. This cooling has been determined, by experiment, to be about 45 deg. C., when the initial pressure is 200 atm. and temperature 0 deg. C. If the initial temperature is -60 deg. C. and pressure is 200 atm., the drop through a nozzle is increased to 73 deg. C. This cooling effect is therefore equal to $0.241 \times 45 = 10.8$ cal. per kg. for the first case or $0.241 \times 73 = 17.6$ cal. per kg. for the second case.

These figures are interesting, when compared with those for the heat which must be discharged during the separation of the air. This figure was shown to be 10.54 cal. per kg. air, and this is practically equal to the cooling effect possible with a plain nozzle working 200 atm. to 1 atm. and at 0 deg. C.

For the purpose of actual air separation, however, an auxiliary refrigeration machine is used, and by pre-cooling to -60 a margin of $17.6 - 10.54 = 7.16$ cal. per kg. may be had, to abstract heat entering the separation system from other causes, such as conduction through the insulation, or along the metal structure. This analysis is borne out by the practical operation of such machines, which require pre-cooling by a refrigeration machine to secure any useful effect. In this case the main current of separated gases can

carry the excess of cooling—i.e., 7.16 cal.—up to the temperature at which the auxiliary system can pick it up, and so discharge the heat to the surroundings.

There is no way possible in nature to increase the cooling by the Joule-Thompson effect, for a given difference of pressure, and starting at a given temperature. Hence this feature is incapable of improvement, except by pre-cooling or by increasing the range of pressure. The pre-cooling appears to be an inexpensive way, and this system really amounts to a double, or binary system; in which the heat liberated by the separation of the air is picked up at, say, -60 deg. C. by a CO₂ refrigeration system, and is then rejected to the atmosphere or surroundings. This is not the usual explanation, but it is a sound presentation of the matter. There is a fallacy in the current idea that this process has a claim to efficiency. The explanation is not difficult.

It will also be found that the other system, which uses expansion engines, has a vital defect in common with the nozzle system and is little better in fact than the nozzle system with pre-cooling refrigerator. The expansion engine may remove 20 cal. or so per kg. of expanded air, and may be said to be from 20 to 25 per cent more efficient than the nozzle system, if the term efficiency is allowable, in a case where the effective work done is less than 10 per cent of the applied work of compression. It may appear that a loss of 90 per cent of the applied work would create some visible or evident result in connection with the apparatus. This is not true; the work of compression may be altogether lost without the appearance of any compensating heat or energy in the system. It is this point which requires clearing up, and it must be said that it is unfortunate that the point has been obscured by defective explanations so that some perfectly simple physical facts have become involved, making the true simplicity difficult to expose. It will be shown that by far the largest loss of power in all existing systems is caused by the simple transmission of heat contents from a high-pressure gas to a low-pressure gas without any apparent or useful effect other than the loss of pressure on the gas. It is not the act of throttling, but the improper heat transfer, which is the true cause of loss of power.

ELEMENTS OF LIQUEFACTION

To fix our ideas, we may take a simple gas, such as oxygen alone, and suppose this to be compressed to a considerable pressure. We may construct an elementary exchanger in the form of a simple U tube, Fig. 1. Suppose oxygen to be compressed into this tube, which may be kept cold at the U end, so that liquid oxygen will collect in the bend of the tube. An auxiliary refrigeration system may be used to keep the tube cold against inward leakage of external heat. Now suppose a throttle valve be placed in the bend of the tube so that the liquid formed in the high-pressure leg will be expanded, say, to 1 atm. pressure. The result would, of course, be that the liquid would become much colder and would at once evaporate, if it could get any heat. If the high-pressure-entering branch be in close contact with the low-pressure-exit tube, it is evident that the liquid may evaporate at low pressure in the second leg, while condensing fresh liquid at high pressure in the first leg. This is a simple form of the nozzle or Linde system, or perhaps it should be called the Hampson type. This very simple apparatus would

FIG. 1. LIQUEFACTION SYSTEM WITH THROTTLE. LINDE OR HAMPSON TYPE

A Air compressor for 3,000 lb. pressure. B Water vessel containing coil b. C Vessel with ice and salt freezing solution and coil c. D Copper tube leading to leg of U tube of very thin copper. M a motor. k Porous plug apparatus for demonstration only.

liquefy air or a simple gas if a pressure of 200 atm. be used. The efficiency is absolutely zero if a simple gas be expanded in this way, except that, in fact, the liquid would accumulate at the bend of the tube and a considerable amount of liquid might be removed as liquid air, oxygen, or whatever the substance might be. In all cases, however, the whole of the work of compression will have been lost, because the gas will issue without pressure, and hence cannot be made to do any useful work—i.e., the gas has lost potential.

Now, suppose that the system is maintained cold by an auxiliary refrigeration, Fig. 2, and that the pressure is only slightly less in the exit tube than it is in the entering tube. Then there would be a slightly lower temperature in the low-pressure tube than in the high-pressure one, and the liquid formed at high pressure could be evaporated at slightly lower pressure in the other leg. In fact, the re-evaporated substance could return to atmospheric temperature at practically its initial pressure. A portion of the issuing gas can evidently be used to refrigerate the system against external heat leakage and losses if desired. We are neglecting this factor for the present, in favor of more vital matters. The gas would have been liquefied, and hence would have passed through a suitable state for distillation (the still is not shown), but the larger portion would issue from the apparatus at high pressure.

RECOVERY OF COMPRESSION WORK THE ESSENCE OF LOW COST

It is obvious that since the high compression of the original gas is the main cost of the whole operation (which, if lost, becomes prohibitive for large-scale operation), we have an obvious means for recovering the primary compression work—simply to heat the escaping gas at high pressure and expand it in a motor cylinder. If a moderate drop in pressure may be maintained (and in fact such an apparatus may work with less than 1 atm. drop in pressure), it is perfectly feasible to heat escaping gas enough, not only to drive the primary compressor, but even to do some extra useful work. This is in essence the fundamental basis of

the Jefferies-Norton system—i.e., to preserve, or conserve, the potential of the compressed gas. This is the primary improvement in the direction of lower cost, simply to avoid throttling.

Now, the case is different for a mixed gas, such as air, from that for a simple gas.

CONDENSATION OF A MIXED GAS

A mixed gas will not all condense at constant pressure and temperature, and conversely it evaporates at constant pressure with a rising temperature. If in our air apparatus we have in some way caused the oxygen and nitrogen to separate, we have the further difficulty that air condenses at a much lower temperature than the boiling point of oxygen at the same pressure. That is, air condenses at 80 deg. C. abs., while oxygen boils at 91 deg. C. abs., both being at 1 atm. pressure. Hence, in our simple U tube we must increase the pressure on the air tube until air will condense while boiling oxygen in the other leg, and the air must be compressed to about 2.8 atm. in order that this may happen. Exactly similar relations hold for higher pressures, and a ratio of 3 may be taken as the compression required. It is evident, on the other hand, that the nitrogen will easily be evaporated while condensing air at equal pressure, since nitrogen boils at 77.35 deg. C. abs. and air condenses at about 80 deg. C. abs., both being at 1 atm. pressure. It is plain, therefore, that the desirable feature of maintaining the escaping gases at substantially the pressure of primary compression will meet an obstacle in the fact that the air cannot be condensed by free exchange of heat with the condensed oxygen, and unless this obstacle can be removed, the project of recovering the work of compression will fail. Unless we can maintain sufficient gas throughout the process at a sufficient pressure, we cannot drive our primary compressor WC (see Fig. 3) by heating and expanding the escaping gas in a motor, and a very desirable economy will be lost. The device of transferring the latent heat of condensation of the condensing air to the evaporating oxygen will now be described.

The distillation of a mixed liquid is a very complex operation to analyze in detail. A few facts stand out

FIG. 2. LIQUEFACTION SYSTEM WITH AUXILIARY REFRIGERATION

clearly, and it will be found that these are the vitally effective points as respecting the economy of the system.

First. The liquid oxygen at the bottom of the still column is hotter than any other part of the column, hence no heat can flow by itself into the oxygen from any other part of the column itself. This fact is self-evident, but the consequences are so far reaching that the full treatment would require more space than we can give. It must be concluded that heat must be added to the oxygen from some outside source, if natural heat flow is to be depended upon. The use

would be to take heat from the nitrogen and reject this heat to the oxygen.

MECHANICAL TRANSFER OF LATENT HEAT

The very simple expedient of placing a coil in the oxygen space at bottom of still, in which compressed oxygen may be condensed, at a pressure very little above the still pressure, will evidently cause the oxygen in still to evaporate (as it must by third condition). The oxygen which has condensed in the coil at the bottom may then be throttled into another coil, at the top of the column, to a low enough temperature to condense nitrogen. If we work the still at 10 atm., we can condense nitrogen at 104 deg. C. abs., by boiling oxygen at 3.5 atm. somewhat below 104 deg. C. abs. In this way we evaporate the oxygen at the bottom of the still in almost perfect exchange for an equal mass of liquid oxygen which would be formed in the coil at bottom of the still. This "transfer" liquid, when throttled to 3.5 atm. and evaporated in the coil at the top of the still, will exchange for liquid nitrogen, which would be condensed out of the vapors at the top of the column. We may have 0.23 kg. oxygen to be evaporated in the upper transfer coil at 3.5 atm., latent heat 49.3 cal. per kg.; the latent heat of nitrogen being 37.5 cal. at 10 atm. Therefore, $0.23 \times (49.3 - 37.5) = 0.3$ kg. of liquid nitrogen may be condensed at the head of the column in exchange for 0.23 kg. liquid oxygen which is evaporated at the bottom of the column by the action of the cold compressor and the heat "transfer system"—i.e., coils at top and bottom of the still. The liquid nitrogen, which would be condensed at the head of the column, would run downward through the usual form of trays, and would cause the condensation of the air in these trays in exchange for higher and higher oxygen liquids which would pass on to the bottom.

REMOVAL OF LOSSES AT HIGH TEMPERATURE

If we could build an adiabatic compressor, the transfer of heat could be made without introducing any heat into the still. Taking the operation as a whole, exactly as many calories would be withdrawn from the nitrogen space into the substance of the transfer fluid as would be given up by the transfer fluid to the liquid oxygen which must be evaporated at the bottom of the column. The heat would simply be taken away from the top of the column and would be restored in equal amount to the bottom of the column, but at a higher temperature. The transfer circuit is thus a simple refrigeration system, taking heat from a colder spot and rejecting it to a warmer one, with the necessary result that work must be used up to drive the compressor.

Now, no compressor is perfectly adiabatic. However, it is fortunate that the effect of imperfection is to superheat the discharge of the cold compressor, which, being at a much higher temperature than the still itself, may be cooled by an expansion engine or other refrigeration means. The temperature being 162 deg. for the adiabatic compression of oxygen at 3.5 atm., we may expect 181 deg. abs. for the actual compressor; so that this extra heat has to be removed between -92 deg. C. and -113 deg. C., in order to compensate for the mechanical imperfection of our cold compressor. Now, the amount of heat which an expansion engine may remove per kg. of fluid varies directly as the temperature of the inlet, or the exhaust; and by raising the temperature to 162 deg. as com-

FIG. 3. SKETCH OF JEFFERIES-NORTON SYSTEM IN FORM OF ENTROPY DIAGRAM

of a condensing coil which contains highly compressed air, to be condensed while evaporating the oxygen, evidently amounts to adding heat from an outside source, and this heat must afterward be removed from the still. (This is the plan usually followed.)

Second. The oxygen in any column must reach the bottom as a liquid. This follows since the still functions solely because the descending liquid always contains more of the less volatile substance (i.e., oxygen) than the ascending vapor, and it is the liquid reflux in the column which carries out the separation of oxygen, by "washing" it to the bottom.

Third. The oxygen must be evaporated in exchange for an equivalent amount of liquid air. This must be true, since no system which wastes the cooling effect of such a large amount of such a cold liquid can possibly be commercial or effective.

Fourth. The liquid toward the nitrogen (cold) end of any column will exchange latent heat with condensing air at the same pressure. This is evident, because pure nitrogen always boils at a lower temperature than that of the air mixture at the same pressure. Granted a sufficient quantity of liquid nitrogen, or high-nitrogen liquid, it is possible to exchange this for an equivalent amount of liquid air by free or natural heat flow at equal pressure.

Fifth. The column must be heated at the bottom and be cooled at the top. The logical proceeding is an unusual one, followed by the Jefferies-Norton system alone. It is this very vital step which advances the art of air separation into the region of fair efficiency and effectiveness. Since a cold spot must be cooled (nitrogen end) and a warmer spot must be heated (oxygen end), it is evident that a proper proceeding

pared to, say, 100 deg. in the older systems, we have increased the cooling effect of the expanders by 62 deg.; or, in other words, the cooling effect per kg. expanded has been increased to 1.6 times that for an engine working at 100 deg. C. abs. exhaust temperature. The superheat may be absorbed into the inlet gas of the expansion engine with a great gain.

The novelty of introducing a compressor to work at these very low temperatures is thus seen to be justified on practical grounds.

The heat transfer system is the direct, natural way to abstract heat from the air to be condensed, and to reject this heat into the oxygen and nitrogen, which have been separated in the still.

THE NEW SYSTEM

The theory of this subject forms a very interesting problem in thermodynamics. It may appear that the positive statements made may not be susceptible of proof, but there are two satisfactory methods available. The first of these is by actual heat content calculations by means of an entropy diagram. Such a diagram has been made, and has been found fairly accurate, so that heat contents may be compared over the whole range of temperatures and pressures. This is a very intricate matter.

The more satisfactory proof is by means of a simple sketch diagram. The idea is to consider a plain tube (N-O, Fig. 3), to be bent to the approximate form of

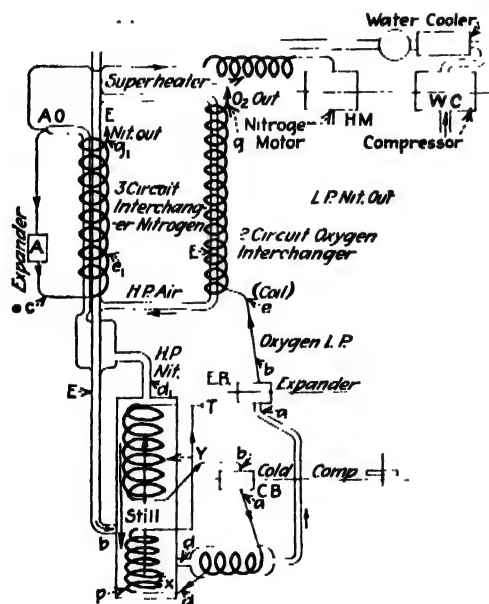

FIG. 4. JEFFRIES-NORTON LIQUEFACTION SYSTEM

the entropy diagram. The passage of a portion of gas, say the oxygen, through the tube will be represented in heat contents and temperature, if it is remembered that areas under the representative line show heat contents.

By the device of superposed coils, like *e*, which are wound around the plain tube, we may perform various cooling and heating operations on the substance in the plain tube. It will be noticed that the plain tube is in reality the U tube of Fig. 1, but that the throttle has been replaced by a pump. This pump is only ideal, and its function is actually performed by heat in the actual apparatus.

This method is an extension of the Carnot theorem,

but using adiabatic-constant pressure lines instead of the adiabatic-isothermal cycle of Carnot. By either method a conclusive proof may be made, but space does not permit the full analysis, which may be found somewhat tedious. We will, therefore, pass on to a description of a working system.

We refer first to Fig. 4 for a schematic apparatus which is lettered to correspond to Fig. 3.

Fig. 3 is a sketch entropy diagram, made closely to scale. Fortunately our proof will not involve any of the peculiar properties of entropy. The working of the apparatus may be followed easily from Fig. 4, which has been reduced to the simplest terms. There are three novel features concealed in this apparent simplicity.

First. The heat exchange is, so far as possible, between gases at as near equal pressure as the friction of the apparatus will permit. That is, the two main currents in the nitrogen-air exchanger *E*, are at equal pressure. The oxygen-air interchanger *E*, however, is cooled by a low-pressure stream, and this is according to the strict theory of the laws of compression of gases in such a system.

Second. The oxygen at the bottom of the still is to be boiled (evaporated) by the introduction of heat at that point, and this heat will be abstracted from the column at the colder top, where nitrogen is to be condensed.

Third. All the expanders work on gas which has passed through the still.

These gases are in both cases warmed up before expansion, by heat which is abstracted from the high-pressure gas in the system. This feature is particularly to be noticed in the case of the oxygen compressor *CB* and the oxygen expander *EB*. All superheating and loss of the oxygen compressor is to be rejected to the inlet of the oxygen expander (*a* to *d*, Fig. 4). The cold exhaust of this cylinder is applied to the compressed air in the exchanger *E*, and this exhaust and the escaping nitrogen from the top of the column are cold enough to condense a considerable amount of liquid out of the entering air. This liquid flows into the still, where it is available to neutralize the external heat leakage and other imperfections of the apparatus. This action is aided by the nitrogen expander *A*, which may, in fact, consist of a pair of engines which are powerful enough to produce a considerable amount of liquid air, to protect the system against external heat leakage. The expanders *A* have no other duty than to overcome imperfections of insulation. The whole of the theoretical cooling required by the separation of the air (compression from partial pressure to total pressure of oxygen and nitrogen) would be performed by the pair of engines, compressor *CB* and expander *EB*. In the 10 atm. system, the oxygen would actually be expanded in *EB* to 1 atm., while it would enter at 2 atm. partial pressure, and this overexpansion provides a margin of cooling, since the compressor need only work through a pressure range from 3½ atm. to 10 atm., while the expander *EB* will work from 10 atm. to 1 atm. The device of cooling the discharge of the compressor *CB* by the high-pressure oxygen vapor from the still will again be noted, as it is most essential that the system be stabilized in this way.

The transfer circuit may easily be followed, remembering that oxygen must be boiled at the bottom of the column and nitrogen must be condensed at the head of the column.

The throttle T differs from the usual throttle, since the coils at bottom are carried up, so the liquid oxygen will be cooled from its boiling point, at 10 atm., to the temperature of liquid air at the entrance of the still; and hence the release of pressure by the throttle T will result in very little fall in temperature and very little evaporation during the throttling. In fact, there would be no loss at this point. This conception is a little difficult to grasp. If the comparison is made with an ordinary water tap, where water, far below its boiling point, is released from pressure without any perceptible drop in temperature, it will be seen that if the oxygen is already cooled to, say, 104 deg. it will evaporate very little in expanding to 3.5 atm., where it boils at 104 deg., while condensing nitrogen in the other side of the tube. This is not throttling in the usual sense. Practically there are certain imperfections of apparatus, but fortunately they may be made to closely approach the vanishing point.

The critical part of this whole system is the possibility of retaining enough nitrogen at high pressure to be superheated to, say, 1,000 deg. F., before expansion in the heat motor HM in order to drive the compressor WC . If 50 per cent of the original air can be returned to HM as superheated nitrogen, the heat will drive the system. The cost of fuel for such a system is very small, since a thermal efficiency of 60 per cent or more is easily reached.

It will be noted that the only useful mechanical effect produced by this system is the separation work—i.e., 10.54 cal. per kg. of air—and this is met by the expansion of the oxygen. The removal of heat leakage has required the expansion of, say, $0.5 - 0.23 = 0.27$ kg. of nitrogen. There is left 0.5 kg. nitrogen to be heated, enough to make good these expenditures of power.

CONCLUSION

The investigation on which these notes are founded has consumed about seven years of research into the problems involved in gas separation. A great mass of information has been accumulated as to the properties of the greatest variety of substances, and the practical side of the matter has been attacked in translating the experimental data into useful form.

It is not to be expected that all points of interest or doubt can be covered in the scope of such a summary as we have been able to make here. There is one fact which stands out clearly beyond any possible doubt: The whole basis of the present oxygen and nitrogen systems is extravagant and uneconomical.

The future of oxygen developments depends on the courage of the industry, in first daring to depart from precedent, and then on active prosecution of both the production and consumption processes. The process of oxygen production is without value unless the demand for oxygen is certain and insistent. We have endeavored to present the claims as to the cost of production fairly, with the view that the application may be as seriously considered. There is no doubt that oxygen and nitrogen will be produced at a price allowable for the fullest development of chemical and metallurgical processes through a process founded on sound thermodynamic principles.

The fact that no ideal process can be carried into practice with perfect effect does not alter the fact that no process which is defective in its basis can be made to exceed its fundamental efficiency. The existing systems are fundamentally defective in two re-

spects, neither being in any way a necessity in the air separation process.

First. The expansion of all the air at very low temperatures, which results in a total loss of primary compressor work, without any compensating benefit.

Second. The introduction of external heat into the still (by the condensation of air at high pressure). The separation of the air requires the compression of the oxygen and nitrogen from their partial pressures at entry to the still to the total pressure on pure gases leaving the still. This means the expenditure of work to a moderate degree, if performed at the temperature of the still. The usual systems violate the natural demands, by compressing air at atmospheric temperature, to perform indirectly the work of separation at a very low temperature, and add to this defective process the further false step of introducing heat into the bottom of the column, which may only be removed by the evaporation of liquid air, as such, without separation.

These defects may be removed by modifications of the cycles; the mechanical processes and the structure of the apparatus may undergo little apparent change.

To secure favorable results: .

First. Transfer the heat contents of all high-pressure gases to return current of high-pressure gas. All heat contents of low-pressure gas to low-pressure gas return. Absorb all heat leakage and loss into high-pressure gas at as high temperature as possible.

Second. Carry out all heat leakage and the heat liberated by separation of gas in the smallest possible current of low pressure gas at the highest possible temperature.

Third. Reduce the temperature difference between any two streams of gas, particularly at the cold end of the apparatus, to the lowest possible amount.

Fourth. Exchange the latent heat of condensation of entering fluids, as exactly as possible, for the latent heat of evaporation of escaping fluids, and avoid the production of liquid air by the cooling effect of nozzles or expansion engine.

Fifth. If any compression work must be done to separate any mixture, do this work at the temperature of separation, rejecting all heat to high-pressure return circuit, with subsequent high-temperature expansion to compensate the system.

By careful attention to these principles in detail, there is no doubt that the costs of oxygen (and nitrogen) may be so reduced that all the applications considered in the first part of this article are feasible. This may be accomplished, without introducing any new physical or mechanical actions, by simply following closely the principles of sound thermodynamics as applied to the relation between heat and work, and to the effect of the transfer of heat contents from a high-pressure gas to a low-pressure gas.

The work represented by the transfer of heat from one temperature to another depends not only on the amount of heat transferred but also on the temperature at which the transfer is to be accomplished. The free transfer by conduction of heat contents from a high-pressure substance to the same substance at low pressure results always in the total loss of potential—i.e., in the loss of the primary work of compression of the high-pressure gas.

No separation process which violates these principles can reach any degree of efficiency which deserves the name.

Production of Sodium and Sodium Compounds in the U. S. in 1919

THE production of sodium and sodium compounds in the United States in 1919 amounted to 9,190,000 tons, valued at \$114,700,000, according to preliminary estimates made by R. C. Wells, of the United States Geological Survey, Department of the Interior. These figures show a decrease of 10 per cent in quantity and 20 per cent in value as compared with those for 1918. The figures showing the production of the various compounds in 1919 together with the corresponding final figures for 1918 are given in the following table.

SODIUM AND SODIUM COMPOUNDS PRODUCED IN THE UNITED STATES IN 1918 AND 1919

	1918		1919	
	Quantity (Short Tons)	Value	Quantity (Short Tons)	Value

(b) Insley, Herbert: "Salt, Bromine and Calcium Chloride," U. S. Geol. Survey, Mineral Resources, 1919, pt. 2.
(c) Figures for 1919 are partly estimated.

The production of sodium compounds derived from natural sources, exclusive of common salt, amounted to 31,890 tons, valued at \$841,903, in 1919, as compared with 24,053 tons, valued at \$992,788, in 1918.

IMPORTS AND EXPORTS

The imports of sodium salts in 1919 amounted to 522,000 tons, valued at \$20,704,000, as compared with 2,111,000 tons, valued at \$90,939,000, in 1918. This great decrease in 1919 was caused almost entirely by a decrease in the imports of sodium nitrate, which is the sodium salt imported in largest quantity, the imports of all other sodium compounds having actually increased in 1919 over those in 1918. The imports of sodium cyanide, sodium ferrocyanide and sodium sulphide were notably greater in 1919 than in 1918.

The exports of sodium salts in 1919 decreased about

17 per cent as compared with those in 1918. As the accompanying table shows, this decrease was due largely to smaller exports of soda ash, as the exports of caustic soda and miscellaneous sodium salts show an increase.

DOMESTIC SODIUM SALTS EXPORTED IN 1918 AND 1919, BY CLASSES

	1918		1919	
	Quantity (Short Tons)	Value	Quantity (Short Tons)	Value
Sodium carbonate:				
Soda ash.....	119,217	\$7,805,550	50,481	\$2,656,608
Sal soda.....	6,358	213,855	5,563	178,285
Sodium chloride (common salt).....	136,783	1,677,577	119,415	1,396,625
Sodium hydroxide (caustic soda).....	48,689	5,602,813	82,116	6,748,762

All other sodium salts.....		6,587,134		7,226,322
Total.....		\$22,291,735		\$18,545,420

EFFECT OF THE WAR ON THE USE OF SODIUM COMPOUNDS

The use of sodium compounds in place of potassium compounds, which was begun of necessity during the war, was largely continued in 1919. The war left the United States with a greatly augmented capacity for producing certain chemicals, especially those used in making explosives and dyestuffs. The manufacture of these materials consumes large quantities of sodium nitrate, all of which is imported, and the work of building up an independent nitrogen industry in the United States has been and still is difficult. The large Government plants projected or built during the war were intended to produce fixed nitrogen compounds in the form of lime-nitrogen, ammonia, and ammonium nitrate. No sodium nitrate produced by the fixation of atmospheric nitrogen has yet been marketed in the United States, but as ammonia is a necessity in the Solvay process of making soda and is used also in making sodium cyanide, any developments in the ammonia industry will eventually affect to some extent the soda industry.

USES OF SODIUM COMPOUNDS

Sodium compounds are valuable either for their basic part or for their acid part. The price of the compounds that are used for their basic part is very low, as the sodium acts only as a carrier of the other elements in the compounds; the price of the compounds that are used for their acid part differs according to the value of that part. Although the price of soda ash is low, the value of the total soda ash produced annually in the United States amounts to millions of dollars and nearly equals that of the total annual production of lime, which is the next cheapest alkaline substance. Soda ash has many and various applications. It is used in making glass, soap, paper, chemicals, drugs, paints, leather, enamel ware, and cleansing agents, in refining oils, and in metallurgy. The uses of the other compounds of sodium vary according to the elements of which they are composed. The uses of the individual salts of sodium, together with a list of producers of each salt, are given more fully in the chapter on sodium compounds in "Mineral Resources of the United States," published annually by the U. S. Geological Survey.

PRICES

The prices of most sodium compounds were considerably lower in 1919 than in 1918. At the beginning of 1919 the prices of nearly all compounds were the lowest for at least three years, but later in the year they improved somewhat and the improvement has continued practically up to the present time.

Legal Notes

By WELLINGTON GUSTIN

Compensation for Death Hastened by Aggravation of Disease Due to Explosion

As a result of an explosion of a still in 1917 in the plant of the National Aniline & Chemical Co. an employee was apparently but slightly injured in the jaw. While the bruise quickly disappeared, a pain in the jaw continued to increase. Upon an examination a malignant cancer was found. The affected parts were shortly removed by an operation, but the disease recurred within a few months and the employee died within six months after his injury.

The State Compensation Board awarded compensation to the employee's widow on the ground that the accident aggravated the cancerous condition and caused death at an earlier period than would otherwise have occurred, the medical testimony indicating that "a local injury might cause an otherwise slow-growing cancer to light up and develop with great rapidity." The award of the Compensation Board was upheld by the Supreme Court of Pennsylvania.

Obligations Upon Agreement to Surrender Contract of Exclusive Right to Handle Product

The Appellate Division of the Supreme Court of New York has affirmed judgment in favor of James A. Cleveland and another in their action brought against Mason J. Clark for balance due on contract. It appears that on July 3, 1917, a contract was made between the parties whereby Mason should deliver f.o.b. the cars at Arnot, Pa., a bituminous product of coal, which he was producing and selling at a certain price, and Cleveland should sell the product and remit therefor, the contract to be in force to May 16, 1922. In July, 1918, the parties entered into another contract, providing for the cancellation of the former contract and in consideration of the surrender of this contract by Cleveland, Mason was to pay \$1,000 down, and balance a later date. Mason refused to pay the balance due after the date fixed. It seems there arose the question of whose duty it was to first perform.

The court said whether the mutual terms of a contract are dependent, so that either party, in order to recover upon it, must show a tender of performance on his part, depends always upon the intent of the parties as gathered from the contract itself.

Where the defendant in a mutual contract is to pay plaintiff certain moneys on a day stated, and neglects to pay them, the plaintiff must tender or offer to tender performance on his part as a condition precedent to his right of recovery for the defendant's default. If there is no express provision in the contract, it will not be assumed that the one party is to pay and give credit to the other for the performance in the future, but upon making the payment he has the right to receive performance by the other party as a condition thereof. Where a contract requires contemporaneous performance, neither party can sue at law until he has, by performance or tender on his own part, put the other in default.

Therefore, the court said, if the subject of the con-

tract was a sale of property, clearly there could be no recovery of the purchase price after the law day without an offer to deliver, as the delivery is the real consideration for the payment.

When the contract was executed and the \$1,000 paid, Mason's liability and Cleveland's obligation under the original contract were at an end, said the court. It would be an idle ceremony for Cleveland to hand over to Mason the duplicate original contract which he held; there was no way prescribed in which their rights were to be surrendered. The contract under seal surrendered the original contract, and the rights of Mason thereunder.

In any event the payment of the \$2,000 would effectually destroy the original contract, and no affirmative action on the part of Cleveland could be had after such payment, and he was not, therefore, required to do any act, as delivery of his duplicate contract, as a condition of maintaining his suit. Judgment for Cleveland was affirmed with costs.

Loss in Shipment of Menthol Acetate Depends on Duty to Unload Under Contract

A new trial has been ordered in the case of the Barton Lighterage Co. against La Brecque Co., Inc., by the New York Supreme Court in Appellate Term. The facts show that the former agreed to lighter 620 drums of menthol acetate from Greenpoint to the New Jersey Zinc Works on the Hackensack River; that loading of the drums began on March 14, but no evidence is given as to how long it was required to reach the zinc works.

The next evidence is that plaintiff's foreman saw the lighter tied to the bulkhead of the New Jersey Zinc Works on April 8; he did not know when it reached there. When he arrived the lighter was listing about 45 deg., and about five minutes after his arrival the lighter suddenly "groaned," turned over and spilled a number of the drums into the water. All but eight were subsequently recovered. Upon these facts the jury found for plaintiff for the full amount of its contract.

The court on appeal said there was no evidence as to whether the contract for lighterage included the loading and unloading of the drums in addition to their transportation. The contract is silent on that point unless the words "to lighter" include, in addition to transportation, the loading and unloading of the menthol acetate to be transported. If the contract included loading and unloading, then the Barton company did not show performance, for the drums were never unloaded completely at the New Jersey bulkhead, and no evidence accounts for the failure to unload, or for the listing of the boat, said the court. But, even if the unloading was no part of the Barton company's agreement and only a mere voluntary act on its part, still there was no complete performance of the contract proved, for it was the duty of the Barton company at least to transport the merchandise in question to the bulkhead in New Jersey in such a way as to give La Brecque company a reasonable opportunity, after the notice of arrival, to unload it.

No evidence was introduced to show these facts required, and for lack of sufficient evidence upon which to base a finding that the plaintiff had completely performed its contract the judgment in its favor was reversed and new trial ordered.

Production of Motor Gasoline From Heavy Oil Hydrocarbons

A Study of the Possible Specific Reactions Taking Place in Cracking Phenomena—Composition of Petroleum—Action of Catalysts Upon Heating—Deposition of Coke—Composition and Refining of Pyrolytic Distillates

By FRED W. PADGETT

PETROLEUM consists essentially of a mixture of hydrocarbons which are in the main totally miscible with one another. Organic nitrogen and sulphur compounds are also present in varying amounts, and occasionally oxygen compounds, as well as water and inorganic material in dispersed form. When this complex of naturally occurring hydrocarbons is subjected to dry distillation at atmospheric pressure, the hydrocarbons of lowest boiling point are vaporized proportionally to their partial vapor pressures and pass into the condenser followed by those of higher boiling point as the temperature rises. Varying degrees of fractionation will obtain, depending upon the design of still and method of operation. From the point where gases first appear at the condenser outlet until the temperature in the still reaches approximately 625 deg. F., the products secured are in the main natural—that is, they exist in the crude oil as such. Above this temperature, however, especially if the distillation is carried out slowly, what is known as "cracking" takes place and a distillate is secured which upon re-distillation

The effect of pressure upon the yield of gasoline and the refining loss of sulphuric acid during pressure distillation is illustrated graphically in Fig. 1.¹ The volumes of gas evolved at various pressures during the course of the distillation is shown in Fig. 2,² while the variation in temperature during distillation and at various pressures is shown in Fig. 3.³ The composition of the gas evolved during various stages of pressure distillation is shown in Table I.⁴ The oil used in the

FIG. 1. EFFECT OF PRESSURE ON YIELDS AND LOSSES

above experiments was Oklahoma residual oil, and the apparatus a small experimental still of the autoclave type.

THE COMPOSITION OF PETROLEUM

Considerable knowledge has been gained concerning the composition of the lower fractions of petroleum due to the researches of Mabery and others. The presence of paraffines, naphthenes (cyclopentane, cyclohexane and their homologues), aromatics and olefines has been definitely established, while the evidence points to the presence also of cyclo-olefines, diolefines and possibly acetylenes.⁵ Concerning the lubricating fractions of petroleum, there is some evidence pointing to the presence of olefines of high molecular weight which are but slightly acted upon by concentrated sulphuric acid,⁶ also diolefines,⁷ polynaphthenes,⁸ and possibly compounds of the hydrogenated naphthalene⁹ and anthracene¹⁰ type. Pressed lubricating oil fractions show, by ultimate analysis, that the average general formula of the hydrocarbons is either C_nH_{2n} or C_nH_{2n-m} .

will yield more gasoline and kerosene, the quality, however, in most cases, not being comparable with that of the natural products.

If, instead of carrying out the distillation above the 625-deg. point at atmospheric pressure in an ordinary still, one of special design is used and the operation is conducted at a pressure varying from 50 to 150 lb. per square inch, profound decomposition or "cracking" occurs, and a yield of gasoline of 20 per cent or more, based on the original charge of residue or heavy distillate, may be obtained upon fractionating the pressure distillate secured. The residue remaining and the pressure distillate which has thus been freed from gasoline may again be subjected to the process and a further yield of gasoline secured, this being less than in the first case, and decreasing upon subsequent treatment.

The pyrolytic researches on individual members of the hydrocarbon series have been mainly carried out on the lower constituents and the data are often conflicting, due to differing rate factors and to inaccuracies in temperature measurements. As a general principle it is known that the relative stability of the hydrocarbons to heat decreases as follows: Aromatics, naphthenes, paraffines, unsaturated hydrocarbons. This general principle, however, must be modified in certain cases, as the following discussion will show:

Where paraffines are present in the residual oils the following will represent a reaction undoubtedly taking place to a considerable extent.*

Gurwitsch¹⁰ believes that the effect of pressure, among other things, is to cause the hydrocarbon chain of the heavier molecule to split nearer the center with resulting decrease in gas formation: namely, *symmetrical scission*. Other reactions, which may take place when hydrocarbons are "cracked," must be taken

FIG. 2. VOLUMES OF GAS AT VARIOUS PRESSURES

into consideration when it is known that carbon is one of the products always encountered during "cracking."

Reaction (2b) is characteristic of "cracking" under pressure.

Local superheating of the oil in contact with heating surface seems to influence the amount of coke formed as well as the character of the hydrocarbons; the asphaltic hydrocarbons, for example, being unstable toward heat and depositing carbon at comparatively low

temperatures. Iron also catalyzes the reaction in which paraffine hydrocarbons are broken down into carbon and hydrogen. (See *infra*.)

The paraffine wax of commerce is not readily acted on by anhydrous aluminum chloride, although the same initial substance upon pressure distillation will yield 20 per cent or more hydrocarbons in the gasoline range."

FIG. 3. VARIATION OF TEMPERATURE AND PRESSURE

Since the residual oils from petroleum may contain not inconsiderable quantities of olefines of high molecular weight, aromatics with long side chains, naphthenes with side chains, polynaphthenes, and even diolefines, it is interesting to speculate how these compounds may be modified by the action of heat, pressure and catalytic agents. Olefines, by the action of heat and pressure, tend to polymerize. It may be that olefines found in the residual oils first polymerize to give closed chain compounds with side chains which are then "cracked" to paraffine hydrocarbons and cyclo-olefines which in turn polymerize to give compounds of higher molecular weight and remain in the still. The following reaction is also one very probably for the olefines, the fact that some petroleum give but little gas during pressure distillation lending support to the hypothesis:

Olefines may also be modified according to the following scheme,¹² diolefines evidently being present in cracked distillates:

This is a reaction which is characteristic of high temperatures.

The naphthenes are known to be more stable toward heat than the paraffines, but with sufficiently severe conditions may be decomposed into diolefines, olefines, cyclo-olefines, benzol, and even paraffines.¹⁴ Hydrocarbons of high molecular weight such as the polynaphthenes, hydrogenated naphthalene and anthracene should be much more unstable than the naphthenes we are familiar with, namely, cyclopentane and cyclohexane.

Anhydrous aluminum chloride readily polymerizes olefines,¹⁵ so that when olefines are present in residual oils, the first action may be the formation of closed chain hydrocarbons with side chains attached which

¹⁰Libbig's Ann., vol. 165, p. 1. This reaction was first observed by James Young.

¹¹Gurwitsch's "Wissenschaftliche Grundlagen der Erdölbearbeitung," p. 145.

¹²In Bulletin No. 14 of the Kansas City Testing Laboratory, p. 96, specific reactions of this type are given.

¹³Brooks and Humphrey, *J. Ind. Eng. Chem.*, February, 1916.

¹⁴Dunstan and Thole, *J. Inst. Pet. Tech.*, vol. 3 (1916), p. 86.

¹⁵*Ibid.*

¹⁶Heusler, *Z. Angew. Chem.*, vol. 9, p. 587. It is known that anhydrous aluminum chloride primarily forms double compounds with the olefines.

are then "cracked" to form paraffine hydrocarbons and cyclo-olefines, with the attendant polymerization of the latter. At this point should be mentioned the work of Pictet and Serczynska,¹ who advance the theory that the residual petroleum oils contain naphthenes with side chains which are acted on by the catalyst to form paraffines and cyclo-olefines, the latter polymerizing immediately by the action of the catalyst and remaining in the still:

Brooks² believes that the higher fractions of petroleum contain aromatics with long side chains, basing his assumption mainly on the fact that upon pressure distillation of the paraffine wax of commerce at 100 lb. pressure no benzols are formed, while upon pressure distillation of various residual oils under the same conditions benzol is one of the products found in the distillate. Phenyl paraffine was synthesized by the Friedel and Crafts reaction and the final product was freed from benzol by steam distillation. Either pressure distillation of this synthetic product or treatment with anhydrous aluminum chloride gave a distillate containing benzol. In order to secure a saturated product from a compound of this type it would be necessary that coke be formed along with very little gas, a phenomenon which actually occurs when residual oils are treated with aluminum chloride:

Summing up the effects of heat alone on petroleum hydrocarbon mixtures of the gas oil type, Dunstan and Thole³ state that at the lower temperatures where "cracking" occurs the products are a mixture of olefines and paraffines; at higher temperatures, near 700 deg. C., a mixture of olefines, diolefines and aromatics prevails, while at still higher temperatures tar and permanent gases containing much methane are produced. From the thermochemical point of view, the main reactions encountered during "cracking" are endothermal, reaction (1) being of this type. In testing the validity of theoretical possibilities the fact that the concentration of the reacting substances has its effect upon the equilibrium, and the law of Le Chatelier, are useful. The latter reads that when one or more of the factors determining an equilibrium is altered, the equilibrium is displaced in such a way as to tend to neutralize the effect of the change. As an example, consider equation (1), which is endothermal. The reaction proceeds toward the right, not spontaneously, but only when heat is supplied. On the other hand, the effect of pressure is to tend to remove the olefines from the sphere of reaction by polymerization, while the paraffine hydrocarbons, by virtue of their stability, find exit by way of the condenser.

That the diolefines have an important bearing upon the formation of aromatics is shown by Davidson,⁴ who believes that the diolefines present in the vapors may combine with ethylene to form benzol:

The effect of pressure should be considered from several angles. In the pressure still it has the effect of raising the temperature to the point where cracking takes place rapidly; furthermore it tends to increase

the yield of liquid hydrocarbons in the gasoline range by *symmetrical scission* of the molecule; and finally it causes the distillate to be less unsaturated. As the distillation proceeds the lighter products are removed as fast as formed. Those molecules which are decomposable at the lower temperatures disappear at the beginning, while the more resistant ones remain in the heated zone, where, by the nature of the operation, they are later modified as the temperature rises. This gives us the distinction between pressure distillation and "cracking" in the vapor phase only; in the former case the best results may be secured by means of *minimum* "cracking" temperatures, while in the latter case *maximum* "cracking" temperatures generally must prevail in order to secure the desired results, as the entire oil (in vapor form) is subjected to the action of heat for only a limited time. The effect of these conditions on the character of the distillate will be discussed later.

The conditions just mentioned as being peculiar to "cracking" in the vapor phase only are modified to some extent by placing expanding drums at the outlet of the coils, where cracking is permitted to continue by heat carried along with the vapors or formed by the reduction of their speed.

THE ACTION OF CATALYSTS

As a means of improving the quality of cracked distillates the method of hydrogenation, which has been so successful commercially for the production of solid fats from those which are normally liquid, suggests itself as a likely method. Hydrogenation of cracked distillates with nickel as a catalyst is made difficult in the case of petroleum for some reason not well understood.⁵ That hydrogenation at lower temperatures without a catalyst does not take place may be illustrated by the following experiment, carried out in the laboratory of the Mellon Institute: A sample of cracked naphtha of iodine value 51 was heated and stirred in the presence of hydrogen at a pressure of 3,000 lb. to the square inch and a temperature of 165 deg. C. for 30 hours, with the result that the iodine value was practically unaffected. If hydrogenation of olefines is to take place during cracking, it must evidently be at the time of their formation.⁶

At higher temperatures (above 200 deg. C.), nickel, platinum and palladium evidently catalyze the reverse action whereby hydrogen is removed from naphthenes, partially or completely.⁷ In fact, it has been shown⁸ that in the presence of nickel at 600-700 deg. C., Russian crude oil gave only coke and saturated gas composed of hydrogen and methane.

It is interesting to note here the work of Jackson and Lawrie,⁹ who claimed that acetylene by the action of high-frequency electric discharge gave a solid polymer which, upon heating, decomposed to methane and liquid hydrocarbons; Losanitsch,¹⁰ who exposed isopentane to the action of the silent electric discharge in vacuo and claimed the formation of hexamethyl

¹Brooks and Humphrey, *J. Am. Chem. Soc.*, vol. 40 (1918), p. 822. On the work of Ellis see *J. Ind. Eng. Chem.*, vol. 7 (1915), p. 1029.

cyclobutane, also noting the rapid polymerization of olefines and aromatic hydrocarbons; Beilstein and Kurbatow,²¹ who secured dinitrobutane by nitrating a petroleum fraction boiling between 40 and 50 deg. C.; and finally Gurwitsch,²² who reports that florida earth and alumina²³ will cause polymerization of olefines, even at ordinary temperatures and pressures.

In certain patents the presence of substances such as coke, iron scrap, alumina, lime, copper, etc., is specified as catalysts to be placed in the cracking zone, the oil sometimes being mixed with steam before entering. If any beneficial action results from these substances it can be attributed more to surface action than to anything else. Davidson²⁴ states that iron, cobalt and nickel catalyze the reaction wherein paraffine hydrocarbons are decomposed into carbon and hydrogen.

TABLE II. RESULTS OF THE CRACKING OF TEXAS SOLAR OIL AT ATMOSPHERIC PRESSURE

Contact Substance	Per Cent Boiling Below 150 C.	Temp. Deg. C.	Time in Hours	Per Cent Loss Gas and Coke
None	8.3	500	0.5	8.7
Pumice	8.8	420	2.0	12.8
Pumice	15.6	500	2.0	17.5
Nickel wire	12.3	500	2.5	17
Nickel wire	18.8	500	5.0	16.5
Nickel on $Al_2O_3 + H_2$	10.5	500	2.5	15.1

Copper gauze	15.2	500	2.5	11.8
Copper gauze	18.8	500	4.5	17.1
Copper gauze + H_2O	15.5	600	2.0	11.1
Iron	4.5	400	2.7
Iron + H_2O	8.6	450	2.0
Iron + H_2O	8.5	480	3.5

In the laboratory of the Mellon Institute,²⁵ it was found that the "cracking" effect "produced in a given quantity in a given time was approximately proportional to the heated surface in contact with the oil," so that if certain metals which are good heat conductors are attached to the apparatus in such a way that heat be transmitted to the oil through a larger surface, advantages might result. An interesting table of experiments in which Texas solar oil vapors were passed over various contact substances is given in Table II.²⁶ It should be noted that the use of these substances is not to be designated as additional "heating surface," but rather as additional "surface effect."

The statement that the "cracking" effect is proportional to the heated surface in contact with the oil must necessarily be modified when the basic principle of the process is the use of superheated fluids such as steam or waste furnace gases.

* THE DEPOSITION OF COKE DURING PYROLYSIS

It has already been mentioned that one of the most serious difficulties encountered during "cracking" is the deposition of coke. Unless removed from the walls of the apparatus very soon after its formation, the coke produced becomes very hard and is difficult to remove. Superheating (hot spots), consequent softening of the metal and finally "blowing out" may be the result of this condition. A majority of the processes include, among other things, methods of eliminating the coke from the heating surface. Thus the Burton process involves a modification in which false

bottoms are used, the Rittman process a revolving rod and chain, the Bacon process vertical heating surface in the presence of liquid,²⁷ and so on.²⁸ One patentee specifies the use of steel balls which are passed intermittently through the "cracking" coil.

It is becoming the practice to utilize heavy distillates for the purpose of cracking rather than the residual oils. In this way the amount of coke produced during the operation is materially lessened. For example, a heavy asphaltic oil may be distilled to coke at atmospheric pressure and certain of the distillates used for the purpose of cracking.

While coke is always formed during "cracking" and is likely to cause trouble if permitted to collect on the heating surfaces, the writer does not wish to convey the idea that "cracking" is always a wasteful process. In carefully operated and properly designed pressure stills using distillates as a starting material, it is claimed that the yield of coke, figured in percentage of original oil charged, is almost a negligible factor, and that the total loss during operation is less than 3 per cent of the original charge. In fact, a "cracking" process in a refinery equipped to separate the crude oil completely into its products consumes less useful or "waste" products, and transforms them, largely, into the more useful product gasoline. The density of the charging material for the pressure stills corresponds to that of gas oil, but is, in fact, a mixture of "odds and ends" from various processes in the refinery.

The analysis of pressure-still coke usually shows rather considerable quantities of iron sulphide.

THE COMPOSITION AND REFINING OF "CRACKED" DISTILLATES

Unrefined "straight run" or "natural" gasoline distillates are composed of varying proportions of paraffines, naphthenes, aromatics, small percentage of olefines and a quantity of organic nitrogen and sulphur compounds generally small, but depending upon the character of the original crude petroleum. Oxygen compounds such as naphthenic acids may also be present in traces. Some of the straight run gasolines which have been secured where direct steam was used in the distillation process require little or no treatment with sulphuric acid.

The gasoline distillates produced by "cracking" contain diolefines in addition to the compounds mentioned above, while the proportions of aromatics are larger.

Mr. Jenkins has subsequently submitted to the writer the following data secured from a run which may be considered as more nearly representing average results:

Time of operation (including heating up), 56½ hr.
Fuel used, 175,975 cu.ft. of natural gas [1,000 B.t.u. at 2½-lb. pressure (gage)].

Total oil charged, 44,467 gal. (gas oil, 33.4 Bé.).

Products:

Gasoline (56-58 deg. Bé., 130 i.b.p., 450 end point), 29.19 per cent.

Naphtha (48 deg. Bé., 470 end point), 9.13 per cent.

Kerosene distillate (39-40 deg. Bé.), 31.98 per cent.

Gas oil (35 deg. Bé.), 3.66 per cent.

Pressure still bottoms (24-26 deg. Bé.), 20.70 per cent.

²¹Ber., 1881, p. 1620.

²²J. Russ. phys.-chem. Ges., vol. 47 (1915), p. 827.

²³J. Ind. Eng. Chem., vol. 10 (1918), p. 901.

²⁴Brooks, Bacon, Padgett and Humphrey, J. Ind. Eng. Chem., vol. 7 (1915), p. 180.

²⁵Brooks, J. Frank. Inst., December, 1915, p. 653.

²⁶The deposition of coke on vertical surfaces is only about one-fifth the amount found on horizontal surfaces.

²⁷In some refineries it is the practice to simultaneously agitate the oil slightly and to scrape the bottom of the still by means of a sweep with chains attached. In the Jenkins apparatus the oil is circulated rapidly by means of a propeller.

Coke, 1.5 per cent.

Uncondensed gas and other losses, 3.84 per cent.

Cracking in the vapor phase only, because of the higher temperatures generally employed, produces larger proportions of unsaturated hydrocarbons and aromatics than in the case of the pressure still.¹⁰ Cracked distillates upon standing may precipitate a resinous product, which is derived, no doubt, from the diolefines and possesses explosive properties when heated.¹¹ The disagreeable odor of these distillates is attributed by some to the unsaturated hydrocarbons, particularly the diolefines. Brooks and Humphrey,¹² however, record that this disagreeable odor is to be attributed more to the presence of organic nitrogen, oxygen and sulphur compounds.

Sulphuric acid acts both chemically and physically upon unrefined distillates, colloidal coloring matter being precipitated and dissolved by the acid, unsaturated hydrocarbons, nitrogen, sulphur and oxygen compounds entering into reaction, the last two mentioned being by no means completely removed. The rise in temperature which is especially marked in the case of unrefined "cracked" distillates when treated with sulphuric acid is no doubt due mainly to the diolefines. According to Brooks and Humphrey, the lower olefines react to form alkyl esters, tertiary and secondary alcohols, some polymerization also taking place. Above the hydrocarbon $C_{12}H_{24}$ polymerization takes place to form di- and tri-polymers which contain but one double bond. In the case of gasoline distillates these polymers dissolve mainly in the hydrocarbon layer, raising the final boiling point.

Likewise, neutral esters of sulphuric acid remain in the gasoline and are not removed when the product is washed with alkali solution; upon standing, the product is likely to precipitate a resinous, viscous layer due to these esters.

It is well known that "cracked" distillates are more difficult to refine successfully than the "natural" products. The loss is likely to be large and the resultant product may be colored, this color tending to deepen upon standing. Ellis and Wells¹³ report that by hydrogenation of "cracked" gasoline was secured a water white product, but they do not give the specific method used nor the constants for the gasoline before and after treatment. Brooks and Humphrey¹⁴ recommend that the unrefined product be treated with not more than 6 per cent of 85 to 90 per cent sulphuric acid followed by redistillation. The writer and his students find that the best results, both so far as color and odor are concerned, were secured by treating the cracked gasoline distillate with concentrated sulphuric acid (1.84 sp.gr.) at from 32 to 40 deg. F., followed by redistillation and washing with dilute alkali¹⁵ or sodium plumbite solution.

In the refineries it is customary to mix the pressure distillate with a large excess of straight run naphtha followed by acid treatment and finally redistillation. In this way a satisfactory product is secured.

For purposes of comparison, constants for crude

pressure still gasoline and crude straight run gasoline, both from the same crude oil mixture, are given below:

Constants	Crude Straight Run Gasoline	Crude Pressure Still Gasoline
Gravity, Bf. degrees (mod. 140).....	57.7	54.3
Refractive index (60 deg. F.).....	1.4142	1.4252
Heat of reaction with sulphuric acid (1.84 sp.-gr.), deg. F.....	25	11
Loss to sulphuric acid at room temp., per cent.....	9	16
Loss to sulphuric acid at 32 deg., per cent.....	5	8

The writer is indebted to W. A. Hamor and W. F. Faragher for many valuable suggestions and assistance in preparing the foregoing article as well as one describing the several processes in commercial use, which is to appear in this journal at an early date.

The Finnish Tar Industry

For the year 1919 the Finnish tar production has been roughly estimated at not more than 50,000 hectoliters, with a value of approximately 8,000,000 marks. Import and export statistics are given below for the whole of 1919 and for the first three months of 1920:

Tar Products	1919		1920 (January-March)	
	Amount	Value Marks(a)	Amount	Value Marks(a)
Exports:				
Tar, he. to liters	11,538	2,604,031	352,789	734,749
Rosin and resin, pounds	789,000	1,459,629	54,800	100,858
Turpentine, pounds	94,600	312,396
Imports:				
Tar, he. to liters	25,794	3,041,709
Rosin and resin, pounds	3,124,000	5,135,862	1,892,700	5,421,485
Turpentine, pounds	39,600	143,772

(a) The par value of the Finnish mark is 19 3 cents. (b) Kilos.

Practically all tar exported from Finland is wood tar, while the imports consist of coal and asphalt tar. The great decrease in the tar production of 1919 is attributed to export restrictions and uncertain prices. Such restrictions did not exist in 1918, and as a result production was very high that year. It is said that America is the only country at present in which there is a great demand for tar, but the high cost of transportation prohibits its shipment there, the freight rates being almost as much as the price of the tar itself. Practically all the tar produced now is for domestic use. The high cost of production and the depreciation of the Finnish mark are great handicaps to the industry, and the outlook for 1920 is very discouraging. Until prices stabilize and export restrictions are removed production will continue to be low.

Drop in Chemical Trade at Hongkong During 1919

There was little life in the trade in chemicals at Hongkong during 1919, and the United States played a minor part in what trade there was, though efforts were made during the year to secure supplies in some important lines from American manufacturers. The value of the trade increased from \$2,264,149 in 1918 to \$2,572,755 in 1919. Imports of saltpeter, which is the heaviest item in the list, were valued at \$459,659 and came from India. There were practically no imports of saltpeter in 1918, the export from India being prohibited. Imports of soda ash were valued at \$228,342, compared with a value of \$120,014 in 1918, and came almost entirely from Great Britain. Caustic soda reached a value of \$194,696, compared with a value of \$210,411 the previous year. Two-thirds of it came from the United States and the rest from Great Britain. There was a decrease in the import of acids, most of which came from Japan. Bleaching powder, calcium carbide, phosphorus and glycerine showed decreases, while imports of alum, borax, quinine, chlorate of potash and sulphur were increased.

¹⁰In the presence of steam it is claimed that a sweeter product is secured. See, however, Brooks, *J. Frank. Inst.*, December, 1916, p. 659, and Davies, *J. Ind. Eng. Chem.*, vol. 3 (1911), p. 114.

¹³*J. Ind. Eng. Chem.*, vol. 7 (1915), p. 1029.

¹⁴*J. Am. Chem. Soc.*, vol. 40 (1918), p. 822.

¹⁵The loss under these conditions should be about half that at average atmospheric temperature.

Data on Operation of Continuous Type Lime-Soda Ash Water Softener

BY R. F. CATHERMAN AND H. C. FISHER

A NUMBER of articles have been published from time to time, giving the theory and practice of water softening, using the intermittent system. The following remarks are of different nature and discuss the problems encountered in the operation of a continuous water softener using lime and soda ash as the precipitating agents. The information given here was gained during the operation of a Booth Continuous Water Softener during a period of six months, sixteen hours per day. Before the operation of the new West End power station of the Union Gas & Electric Co., Cincinnati, Ohio, power was generated at the old Plum St. station, which was situated on the Miami and Erie Canal, the waters of which were used for boiler feed and condensing purposes. The apparatus mentioned was used to prepare

FIG. 1. CONTINUOUS TYPE WATER SOFTENER

water for the boilers, a task that was difficult because of the many variable factors entering into it.

The general layout of the plant is shown in Fig. 1. Water from the canal entered the mixing tank C from the automatic weir B, where chemical solution from tank A was pumped through B into tank C. The treated water then passed along a trough to settling tanks D, E, F and G, after which it was forced through

FIG. 2. SYSTEM BEING BROUGHT TO EQUILIBRIUM

a sand filter and up into a preheater. Specific dimensions have no particular bearing on the discussion and will, therefore, be omitted. (Capacity of softener—14,000 gal. per hr.)

WATER SUPPLY VARIABLE

The fundamental part of the whole system was the weir, which was so arranged as at all times to admit 650 parts raw water to 1 of chemical solution, by volume. Theoretically, knowing this relation and the con-

stitution of the raw water, the necessary charge can be calculated. However, this was not practical, considering the raw water from the canal. This stream was used as a means of sewage disposal by a large number of industrial firms in the Mill Creek Valley, such as tanneries, dye works, soap factories, distilleries, etc. Using

FIG. 3. VARIATIONS IN TOTAL HARDNESS WITH CHANGES IN METHYL READING

Clark's soap solution, which was considered sufficiently accurate for the purpose in hand, the hardness of the raw water was found to vary widely between 15 and 40 deg., a constant condition never being maintained. Sulphates usually constituted 50 per cent of this total hardness. Analysis showed calcium, magnesium, barium and iron to be present in amounts decreasing in the above order. Besides these minerals, large amounts of organic matter were present, sometimes to such an extent that the quantitative analysis was rendered very difficult. As will readily be seen, the above conditions, combined with extremely variable loads on the system, presented a difficult problem in softening the water.

ANALYTICAL DATA DETERMINATIONS

Assuming that the reader is acquainted with the chemistry of water softening, using the lime and soda ash method, the quantitative reagents will be discussed. The total hardness of the treated water was found, using Clark's soap solution so standardized that 1 c.c. was equivalent to 14.3 parts of hardness per million parts of water, expressed as CaCO_3 . Titration of a sample of 100 c.c., using hydrochloric acid of Clark's degree strength and phenolphthalein as an indicator, gave the causticity or C reading. Further addition of methyl orange and continued titration gave the alkalinity or A reading. The difference between them, $A - C$, was termed the M or methyl reading. Since the water was acid in character, these readings were obtained on the raw water with the exception of C.

INTERPRETATION OF DATA

As before stated, the variable factors in the system made it impossible to calculate the chemical charges. Upon assuming control of the plant, therefore, experiments were performed to obtain relationships between the H, C and M and the A readings. Fig. 2 shows the relations during a period when the system was being brought to equilibrium. It shows that as the hardness decreases, the M reading approaches a value that is constant for any given raw water. Considering another typical period as shown by Fig. 3, it is seen that as M deviates markedly from the equilibrium value of that particular water, H rises. Explanation of these facts may be as follows: Hydroxyl ion must be present in amount sufficient to precipitate all bicarbonates and still provide a slight excess over this amount. By the law

of mass action, this excess increases the precipitation and also provides for any sudden increases in the temporary hardness of the raw water. During the above period, Na_2CO_3 is removing the sulphates, and is also provided in slight excess. Consider a case when the hardness of the raw water is decreased, both temporarily and permanently in approximate proportion. Such a case indicates that the excess chemicals cause the production of hardness, the CaCO_3 forming a gelatinous precipitate

Too large an accumulation of carbonate precipitate in the settling tanks was always accompanied by an increase in hardness despite the condition of the causticity and alkalinity, hence the justice of the above statement

FIG. 4. SYSTEM APPROACHING EQUILIBRIUM

seems established. The excess NaOH gives rise to a high C reading, which, when combined with the high H and A , instantly showed that a too large excess existed, and steps were always taken to remedy the condition. Partial drainage of settling tanks always facilitated matters, at the same time preventing a high alkalinity.

CALCULATION OF LIME AND SODA ASH CHARGES

Formulae for the calculation of charges, as given by the designers of the plant, were based upon the findings of the American Public Health Association. These principles are sound, but must be interpreted with great care in all cases. The specific directions given were somewhat fallacious, as proved by long periods of inefficient operation experienced in their use. As mentioned before, there was an equilibrium point which marked the lowest attainable hardness. This point was defined by the titrations, the methyl reading being the most significant. Efforts were always bent toward keeping the hardness between 3 and 4 deg. Clark. In this range of hardness, as shown in Fig. 2, the typical readings were identified by methyl readings averaging from 0.6 to 0.8 deg. Of course, it must be understood that the constant changes in the constitution of the raw water made actual calculations and results variable, but examination of typical report sheets shows the truth of the statement. Since direct calculations were not feasible, resort was made to the data for a solution of a different type. Taking a problem for explanation, let the following be the conditions:

Treated Water					Charge				
Time	H	C	M	A	Time	H ₂ O, In.	Lime, Lb.	Soda, Lb.	Lime, Lb.-Ft.
7.40 a.m.	8.7	0.9	1.6	2.5	8.15 a.m.	12	165	32.0	165 32.0
9.20 a.m.	8.9	1.5	1.1	2.6	9.40 a.m.	6	92.5	27.5	185 55.0
10.50 a.m.	7.5	1.2	0.8	2.0	11.10 a.m.	6	100.0	30.0	200 60.0
1.00 p.m.	4.7	1.0	0.8	1.8	1.15 p.m.	6	108.5	30.0	217 60.0

(and so on through the day)

Calculations were found to obey the following proportions, in which the only factors that entered were those concerning the condition of the treated water, an obvious fact since the condition of the raw water is reflected in that of the treated water. In fact, the hardness of the raw water was only used as a comparative basis for the approximation of the charges needed when starting the operation of the plant after having, for some reason or other, had it out of service. As found, $C = 0.9$ deg., $M = 1.6$ deg., and $A = 2.5$ deg.; therefore knowing that that value of C is too low and that the value needed is probably 1.5 or a similar one, the ratio of these values is equated to the ratio of the last charge of lime to the unknown one. (All charges based on foot depth of chemical tank.)

$$\frac{\text{Existing } C}{C \text{ necessary for equilibrium}} = \frac{\text{Last charge of lime}}{\text{New charge of lime}} \quad (1)$$

Knowing also that the equilibrium value of M is a fixed quantity, the next step is to form a ratio between values of M in a similar manner.

$$\frac{\text{Existing } M}{C \text{ necessary for equilibrium} + \text{correct } M} = \frac{\text{Last charge of soda}}{\text{New charge of soda}} \quad (2)$$

ing the above:

$$\frac{0.9}{1.5} = \frac{100.0}{x} \quad x = 166 \text{ lb. lime} \quad (1)$$

$$\frac{2.5}{2.3} = \frac{35.0}{x} \quad x = 32 \text{ lb. soda ash} \quad (2)$$

The variations from the actual calculated results, as seen in parts of the given tables, emphasize the personal equation which enters the operation of a continuous type water softener.

EXPERIMENTS WITH NaOH

During a period of three days experiments were tried with the use of sodium hydroxide as the softening agent. The theory leading to the use of caustic soda was based

FIG. 5. SYSTEM AT MAXIMUM EFFICIENCY

on the consideration that the bicarbonates would be precipitated by the hydroxyl ions, as happens with the use of caustic lime, producing simultaneously sodium car-

bonate, which would react with the sulphates present, thus removing them.

The comparative success of the experiment suggested a few questions:

At what period during the experiment was precipitation of sulphates initiated?

What was the behavior of the causticity? The alkalinity?

What factor controlled the lowest attainable hardness?

Examination of Fig. 4 shows that the permanent hardness was precipitated from the beginning of operations, that no hydroxyl was present at that time, and that as the causticity increased the total hardness diminished and the alkalinity remained constant. Applying the correct formula, it is seen that for the system approaching equilibrium the HCO₃ averaged 5 deg. as the SO₄ decreased from 8.9 to 1.4 deg. The day of best efficiency is shown in Fig. 5. Since that day is typical, the calculations are given in the accompanying table.

The large carbonate readings are attributed to the total elimination of sulphates and the consequent production of excess Na₂CO₃. Owing to the many factors entering the system, nothing specifically numerical can be stated concerning this. One outstanding fact is presented by the data—namely, that if a constant charge can be used after reaching the equilibrium point, the total alkalinity will not increase. An increase in the concentration of the charge, after reaching that point, is accompanied by a rapid increase in the alkalinity.

Union Gas & Electric Co.

Gas Appliance Investigations by the Bureau of Standards

The investigation of gas-burner design and operation, begun last year in co-operation with the industrial fuel committee of the American Gas Association, has been continued actively throughout the year. This work is an essential preliminary to investigations which have been in mind for several years looking toward increased efficiency in the use of gas. The proper design of air shutter, gas orifice and burner throat to give the maximum injection of air under ordinary conditions was the part of the problem particularly assigned to the bureau. Some months were spent in designing and developing suitable apparatus for making the necessary measurements of the air and gas, but the time thus spent was well worth while, as the equipment developed proved so satisfactory that results have been obtained with unusual rapidity. This work has been done on experimental burners representing a wide variation in dimensions.

Discontinuance of Crude Camphor Export Allotments by Japan

The Japanese authorities have decided to discontinue the allotment of crude camphor to camphor refiners in the United States and other countries foreign to Japan. This step has been taken as a measure of relief to the Japanese camphor refiners, who are in serious straits, owing to the depression in the celluloid industry. Japanese camphor refiners are concerned with nothing but camphor, while it is understood American camphor refiners are concerned with that product only as one of a number of others with which they can keep their plants busy. It is therefore believed that American camphor refiners will not be especially inconvenienced.

In order to offset any possible loss, the authorities have decided to allot to refiners in the United States, at a special discount, 15,000 lb. of refined camphor a month. During the year ended March 31, 1920, only about 64,000 lb. of crude camphor was allotted to camphor refiners in the United States. A much greater quantity of the refined, however, is allotted, so that American refiners may, with the special discount and the greater quantity, obtain at least their usual profit for handling camphor. The price for refined camphor is 290 yen (\$144.56) per 100 lb.

This action does not alter in any way the allotments of "B" and "BB" grade camphor to celluloid manufacturers. In fact, the authorities are hopeful of being able to increase production during the fall and winter of this year so that allotments to celluloid manufacturers may approach nearer the maximum figures than has hitherto been the case.

New Electric Power Plants in Italy

In the territory of Treviso the Società Adriatica di Elettricità, together with the Società del Cellina, is running two hydro-electric power plants, which are situated at Fadalto and Nove, on the lakes of Santa Croce and Morto, capable of producing, respectively, 20,000 and 8,000 hp.

On account of the unusual demand for electric energy for illumination, industries, drainage installations and agriculture, due largely to the prohibitive price and scarcity of coal, these two societies have decided to immediately execute a program for augmenting their production, and both are working at present in order to transform their plants and increase their production to approximately 280,000 hp.

Once the work is accomplished, they will dispose of 700,000,000 kw. of energy, in comparison with 32,000,000 kw. at present, which would mean a saving for Italy of about 1,000,000 metric tons of coal per year.

To carry out the program the societies will have to spend about 220,000,000 lire in five or six years.

Practical Notes on the Design and Treatment of Steel Castings*

A Discussion of Foundry Practices Necessary to Avoid Cracks, Draws, Honeycombing, Cavities and Such Defects—The Importance of Heat Treatment Is Emphasized, It Being Noted That Correct Methods Give Castings Equal to Forgings in Physical Properties

By GEORGE F. PRESTON

IT IS much to be regretted that, between engineers and steel-founders, there is so little interchange of the knowledge gained by experience on the subject of the production and treatment of steel castings, a subject of very considerable importance, as greater reliability in steel casting would result from a better understanding of requirements and difficulties by users and suppliers.

Steel castings are used extensively for very diverse purposes. Some difficulties which have arisen in the foundry have been due to the non-appreciation of the fact that, at the recalescence point A_r , in the cooling curve of steel contraction is arrested and an actual expansion takes place. In an ordinary 0.3 per cent carbon

FIG. 1. CYLINDER WITH DIFFICULT BED PLATE

steel the expansion between 690 and 650 deg. C. is approximately equal to the amount of contraction between 790 and 710 deg. C.; therefore in some castings of intricate design reversals of stress do not occur simultaneously in all parts. If such castings are left in the sand or on the floor, cooling at unequal rates in various parts, contraction will be taking place in some portions, while in others expansion will occur, when adjacent members are in a plastic or weak condition, resulting in pulls or cracks. When such difficulties due to reversals of stress occur, modification in design, so as more nearly to equalize the thickness in critical parts, affords one means of remedy. Another is by chilling or using one of the various methods, not altogether looked on with favor by the engineer, for making the thicker sections cool more rapidly where feasible, or, for any other reason, not undesirable.

USE OF CHILLS

Most steel-founders have probably experienced cases where the use of chills has been followed by cracks in the casting, through the effect of using such chills not having been fully considered. An alternative method which might be adopted for some castings is to arrange for the cooling from a temperature above 770 deg. C. to take place in a preheated furnace, care being taken to strip the casting at a temperature sufficiently above

this to enable it to be sealed up in the furnace before the temperature has fallen to the danger point. This method was adopted with success in the case of a casting for a ship of world-wide repute, having a heavy flange, or seat, about the middle of its length, after several unsuccessful attempts had been made to obtain a satisfactory casting by other means.

Cases occur where the engineer would be put to increased cost, or experience a difficulty, by omitting some portion objected to from the founder's standpoint, as, for example, in a cylinder or tube such as that shown in Fig. 1, having a heavy flange, XX' , 2 to 4 ft. from the mouth, and used only for bolting the cylinder on to its bed plate, which present two difficulties to makers. One is to feed the square flange to insure soundness; the other, which is possibly of more consequence, is to prevent pulling in the bore of the cylinder about the center of the width of the flange at A . In such cases probably no really serious objection could be raised to introducing in this heavy flange a frame (Fig. 2), previously cast in steel, to act as a chill, thus equalizing the rate of cooling and also insuring an absence of cavities in the surrounding metal. There would be little theoretical and probably no practical loss of strength, as unless the chill was of excessive thickness it would to a large degree be fused by the fluid steel.

FEEDING HEADS

In the case of important castings subjected to severe stresses, such as large gun mountings, etc., the fullest and most careful consideration should be given by the designer to the placing of heavy masses or sections of

FIG. 2. SUGGESTED CHILL FOR FIG. 1; TO BE PREHEATED

metal where adequate arrangements can be made for feeding, as, in the absence of feeding heads, the thinner surrounding sections will draw on such reservoirs of molten steel and result in unsoundness or piping in

*A paper read before the annual meeting of the British Iron and Steel Institute, May 6, 1920.

parts where it is of the utmost importance that a large factor of safety should be provided.

The making of a ship's stem free from defects might be instanced as an illustration of this important point as to the position and size of necessary feeding heads, to insure soundness, or, on the other hand, of alteration in design to obviate them—a problem which, owing to the great divergence in the types of castings required by users, is relatively more difficult of general solution (even if not of the same importance) than the recently much discussed question of producing sound ingots.

Such a casting usually has heavy brackets cast between the webs at the deck positions, large radii, advisedly, being usually formed, thus further increasing the relative mass at these places. There is little doubt that a more satisfactory casting would result (even if, superficially considered, such does not appear to be the case owing to unsoundness of piping not being apparent on the surface) by breaking the continuity of the junction of the bracket with the section of the webs, particularly at the extreme forward point, as such recesses in the deck brackets can safely be filled in later by electric welding and calked to make perfectly water-tight. If feeding heads are placed over these brackets, the steel will remain fluid at these places after the general contour of the stem casting has solidified, thus tending to unsoundness, distortion and troubles through contraction. Another point which should be borne in mind in connection with castings of this type is that during the period of cooling after casting the curved contour will tend to approximate to a straight line. Allowance should therefore be made by the pattern-maker for this tendency, particularly toward the two ends. When the annealing, or heat treatment, is carried out the contortion which would probably result if flames are allowed to impinge on the casting must be guarded against before the furnace is closed.

Modifications in design would be the more satisfactory expedient in some cases which come before the steel-

FIG. 3. WHEELS WITH RIBS UNDER INTERNAL FLANGE AND HEAVY CONE CENTER.

founder, parts being made separately where possible. This has sometimes the objection of increase in cost of machining, etc., but cheapness should not be the sole consideration in making such castings.

Castings of the type shown in Fig. 3 are sometimes asked for, with light ribs, AA, tied under internal flanges and also to a heavy plate or cone center, CC'. Such ribs naturally cool at a much quicker rate than the heavy disk portion and feeding heads, XX', and are therefore in considerable tension, where the members join the periphery, when the plate portion and the center boss have reached their maximum contraction.

It is likewise a difficult matter to insure perfectly

satisfactory casting of such design as shown in Fig. 4. This shows a disk, or wheel, having spokes of heavy rectangular section on which are superimposed a plate of lighter section. Drawing or other defects will probably appear in the plate over the center of the spoke or rib (see X on section *ab*).

It must be admitted that a careful consideration by the management (and especially a joint discussion with all foremen responsible for seeing work through the different shops) of the problems to be faced in these and similar instances would conduce to the production of better castings; as it is sometimes seen, after a pattern is completed, that if it had been made differently in some respect, to allow of a modification in the method of making the mold, provision could have been more efficiently made for feeding, and also for guarding against contraction and other troubles.

Such expedients as the insertion of tubing of small diameter and of considerable length rammed with sand,

FIG. 4. "DRAWING" OVER DEEP RIBS

in lieu of cores where they are surrounded by large masses of steel—which cores would necessarily have to be made hard to stand and would become much more so through the contraction of the steel—would probably then be arranged for and much expense be saved in fettling and in the machine shop. It is well known that bent or broken cores cause endless trouble when the casting reaches the drilling machine; in fact, in many instances it would be far cheaper to omit small bolt-hole cores altogether.

There is also a danger of small cores in one plane (say for a number of bolt-holes) causing vital cracks in large castings of heavy section, owing to contraction, the cores becoming very hard and offering great resistance while the steel is semi-plastic.

HONEYCOMBING

Steel-founders of repute have overcome the trouble of honeycombing and blowholes in castings. These in earlier days were considered almost unavoidable, in fact it has been stated in the past that the presence of blowholes might be taken as a "guarantee of quality in other respects"!

Given steel properly melted and with suitable percentages of silicon and manganese, and care in making and drying molds, little trouble is experienced in this respect; piping, sand defects, etc., being far more frequently the cause of discards.

The elimination of honeycombing has resulted in very largely increased productions of cast steel blanks for machine-cut gearing and similar castings, on which a large amount of machining is done; but, owing to the serious loss which would be incurred if defects developed, particularly at a late stage in the machining operation, it is very necessary that everything which can possibly be done to insure perfection should be given earnest consideration. Arrangements should be made

for the fluid steel to enter the mold at the bottom, and whenever possible a centripetal action, commonly termed "spinning," should be secured. Suitable risers and feeders should be provided where necessary, to insure any dirt being brought up into the heads. It is usually advisable to cast such articles quickly.

Castings of this kind are frequently produced without the slightest defect, provided the design be favorable. One cause of trouble has been due to the founder being asked to supply blanks of fairly large diameter with solid disk, or plate, centers, which have a pronounced tendency, in large diameters, to result in cavities being formed in the rim, practically in the position where the roots of the teeth are when these are "milled" out. (Fig. 5). This is due to the rim being of heavier section than the disk and therefore remaining fluid longer, and also, in cases where the change in section is not so great, to difficulty in arranging for adequate feeding at this place.

It is preferable to adopt H-section arms, but it is then found expedient to break the continuity of the metal at the junction with the rim by placing a narrow

FIG. 5. HONEYCOMBING AT JUNCTION OF RIM AND ARM

core through the webs of the arms. If objection be made to such a method resulting in any weakening of the casting, this can easily be obviated by increasing the strength of the faces, or top and bottom flanges, of the arms by having larger radii between them and the rim (see XX' Fig. 6), which is preferable from the founder's standpoint as well.

The same problems are encountered in the production of smaller castings, weighing from a few ounces upward, as supplied to motor and general engineering firms.

The difficulties might be overcome in many instances if it were possible to arrange to submit suggested designs to some steel-founder of good standing beforehand.

It is not intended, however, to convey the impression that all faults lie with the drawing-room, as by careful attention and thought on the part of the foundry staff better articles could be produced by judicious use of chills, feeders, etc. Further interchange of opinion would, however, undoubtedly lead to increased efficiency and obviate some of the troubles experienced by the engineer.

To give one example only: Axle-box guides for locomotives are still made as shown in Fig. 7A, which any user will understand generally results in "drawing" at X and X', in addition to causing extra work in the machine shop owing to the absence of tool clearances, instead of a more gradual change in section and also of radii at the corners, as illustrated by Fig. 7B, the more usual present design.

Innumerable examples might be adduced affecting practically every type of steel casting made, but the desire at the moment is to persuade the engineer

that exchange of views is of importance not only in respect of the production of castings without inherent weaknesses, but also in regard to the use of differing qualities of steel, or of special alloy steels, for various purposes.

The provision of suitable test-coupons, in the case of some forms of castings, is an important matter if sound pieces for tensile and bend tests are to be insured. This should not be left to the discretion of the molder, who is usually, in deciding where to place these, governed by considerations of convenience in respect to the molding-box used for the job. The question is well worth consideration by the management, owing to the loss incurred if a satisfactory casting be rejected solely through inability to obtain test-pieces free from defects. In some cases, on cutting up a casting for test to represent others produced from the same cast of steel, or on breaking it under the tup for re-melting, it has been found that the casting was perfectly sound, defects appearing in the test-pieces only.

It is also highly advisable to provide for spare test-pieces, as cutting pieces from rising heads often results in disappointment from causes such as segregation.

Consideration should be given to such points as feeding the test-bars, and whether the steel is able to flow freely through the part provided for tests; whether any dirt carried off the face of the mold, etc., may be trapped, and whether the test-bar will be sound at the expense of unsoundness in the casting itself or *vice versa*.

For small castings it is advisable to treat the test-bar as a separate casting but connected by a "spray" of sufficiently large sectional area to insure that the test-piece is securely attached to the group of castings, or to the single casting, as the case may be, and also to give an adequate flow of steel into the test-bar, on which a separate feeding head should be superimposed. A suitable design of test-piece for this purpose is shown in Fig. 8.

The provision of test-pieces from small castings may add very considerably to the cost of production, especially in cases where only a few are required from a pattern. This should be borne in mind when quoting, and the most favorable arrangements made with the inspecting engineer as to including a quantity from one cast of steel as well as from a single molding box.

FIG. 6. CORE AT JUNCTION OF H-SECTION ARMS

When molds are made by machines, it will be found convenient to arrange the patterns on the plate, whenever possible, so that one or more patterns can easily be removed and a test-bar included in place in several of the molds for each cast. Special attention must neces-

¹Hydraulic cylinders having square instead of rounded or spherical ends, for instance.

sarily be given to the method of fastening patterns to the plate to prevent any possible chance of displacement through the more frequent changing.

HEAT TREATMENT

To insure satisfactory test result it is necessary that the annealing or rather heat treatment (as the great majority of castings are now cast in mild steel and annealing—i.e., softening—to permit of the castings being readily machined was principally required for crucible steel castings) should be carefully carried out. It is very advisable to have some means of recording temperatures, reading being taken in various positions in larger furnaces; at any rate until it is ascertained that something approaching a uniform heat is obtained in the particular type of furnace in use. The furnace attendant, if left to himself, often appears specially interested in recording flame temperatures rather than those of the castings under treatment. If personal attention is given, by some one holding a responsible position, to this matter of heat treatment, economies in working, as well as higher quality material, etc., may result, as small modifications in furnace design—for instance, slight alterations in the sizes and positions of admission ports—may be found advantageous.

There is no doubt that an experienced workman can judge temperatures to within a reasonable variation, at

FIG. 8. TROUBLESOME AND APPROVED DESIGN FOR AXLE-BOX GUIDES

any rate under the atmospheric conditions he is accustomed to, but it will usually be found that the tendency is to estimate the temperature higher at night than in daylight, and the cost of a pyrometer is money well spent.

The most satisfactory furnace is one in which the rate of cooling down at the critical temperature can be varied to some extent, as it is then possible to obtain small variations in the maximum stress where castings are made to stringent specifications.

Owing to the difficulty sometimes experienced in obtaining permission for material, which has given results, say, 4,000 to 6,000 lb. over or under the tensile strength specified, to be re-treated, it would appear that some engineers have not yet realized that the rate of cooling through the recalescence point of the steel governs the tensile strength, and that a substantial increase or decrease can be made by accelerating or lengthening the period of cooling through this range.

It is found in practice that heating to a temperature of about 950 deg. C. is advisable to insure the breaking down of the cast crystalline structure, the final structure of the ferrite and cementite being, of course, coarser or finer according as the rate of cooling through the critical range is slow or rapid. This temperature is much higher than is theoretically necessary, but experiments over a considerable period show the necessity for the higher temperature. The original crystallization of a casting

will, of course, be governed by the mass of metal, and the rate of cooling after casting either in the mold or, if knocked out, early after casting, on the foundry floor.

The length of time necessary throughly to soak castings and complete the breaking down throughout is a variable matter depending on size, thickness of metal, position the castings are loaded in the furnace, and probably several other considerations.

When dealing with large castings of heavy section it is advisable to pack them well up from the floor of the furnace. If this can possibly be done, pieces having heavy cores should be rough fettled before being placed in the furnace. The annealing will then be more efficiently and expeditiously carried out.

Generally, if arrangements are made which will admit of castings being cooled off quickly through the critical

FIG. 8. SUITABLE DESIGN FOR TEST PIECE

range without risk of distortion, setting up of stresses, etc., through currents of cold air impinging on one part of a casting, or other causes, an increase in the tensile strength without decrease in the elongation can be looked for and, owing to the closer structure, better results from bend and shock tests obtained.

Many cases have been noted where mild qualities of steel, as cast, have given practically the same tensile strength and elongation as after annealing—for instance, a breaking strain of about 60,000 lb. per sq.in. with 28 to 30 per cent elongation in 2 in. Untreated samples fail, however, to give anything approaching satisfactory bend tests.

SHOCK TEST

It is possible that manufacturers of high-quality castings may soon consider that some form of shock test might by no means be against their interests if lower grade material, less suitable for the purpose required and supplied at a cheaper rate, be in this way eliminated from competition. The importance of the annealing or heat treatment of steel castings has been specially mentioned in papers read at various times, and a study of these is well worth the time so spent by anyone responsible for the production of steel castings, as are also papers which have recently been read on steel ingots, the problems requiring solution being closely allied.

The aim of every maker should be to produce castings absolutely, not commercially, free from defects, and the engineer should be willing to give earnest consideration to any reasonable modifications which may be suggested by men of experience. By close co-operation, steel castings might be produced which could be used with the same confidence as is extended to forgings when it is borne in mind that practically the same structure in the steel can be obtained by correct heat treatment as by work done on the steel during the process of manufacture.

ROLLING OF CELLULOSE-ACETATE-BASE CELLULOIDS

Manufacture of Cellulose Acetate*

Generalities on Cellulose Acetates—Esterification—Operating Conditions—Industrial Manufacture by the Acetylation of a Modified or Natural Cellulose With or Without Solution of the Cellulose in the Esterifying Bath

By MAURICE DESCHIENS

THE chemistry of cellulose acetate has been greatly developed during the last few years. This product finds now extensive use in a great number of industries, especially in aëronautics, films, non-flammable celluloids, imitation coral, amber, shells, ivory, artificial flowers, non-breakable and flexible window glass, transparent sacks, electric insulators, artificial silk, etc.

GENERALITIES ON CELLULOSE ACETATE

The composition of cellulose might be given as $(C_6H_{10}O_5)_x$ or, if x is assumed to be 12, $C_{72}H_{120}O_{60}$. The simplified formula may be written as $C_6H_{10}O_5$.

The three best-known acetylated derivatives of cellulose by acetic acid and anhydride in the presence of appropriate catalysts are

$C_6H_9O_5(OCOCH_3)$ = mono-acetate

$C_6H_8O_5(OCOCH_3)_2$ = di-acetate

$C_6H_7O_5(OCOCH_3)_3$ = tri-acetate or normal acetate

The cellulose acetylation reaction does not consist in a simple substitution of the alcohol radical OH by an acid radical, but is in reality very complex due to the fact that partial hydration of the cellulose may take place during the normal acetylation process, or coincident with or following the acetylation, with the result that there is an undetermined number of inter-

mediate products of hydrocellulose acetates as proved in the determination of viscosities, solubilities and saponification indices.

From the technical and industrial point of view the tri-acetate is the only one of interest and the acetylation methods are for the production of this acetate. Industrially it is difficult to obtain the tri-acetate as the final product, as this is mixed with lower acetates, especially the di-acetate $C_6H_8O_5(OCOCH_3)_2$, and compounds of partial hydrolysis (hydrocellulose acetate and hydrocellulose). This is due to the complexity of the esterifying bath, which contains sometimes cellulose, oxycellulose (action of oxidizing agents on the cellulose), hydro-cellulose (hydrolysis of cellulose) and acetic esters of cellulose. When sulphuric acid or sulphates are used as catalysts, sulphuric esters are also present (action of sulphuric acid) and acetosulphuric compounds (combined action of acetic and sulphuric acids), all in the normal and partially hydrated forms. Besides, there may also be present one or more series of cellulose decomposition products in different states of hydrolysis and esterification.

From the examination of industrial acetates of different origins it is possible to conclude that even the acetates prepared in the same plants by the same processes have variable solubilities and viscosities and no relation can be established between the contents in acetyl of these acetates and their physical and

*Abstracted and translated from *Chimie et Industrie*, May, 1920, pp. 591-607.

chemical properties. It can be said, though, that the presence of sulphuric acid or sulphates in the cellulose acetates produces instability and exerts an appreciable influence on the solubility.

It often occurs that cellulose acetates which analytically are identical have very different physical properties.

A series of analyses has shown that: The percentage of the cellulose acetate which is insoluble in acetone varied from 3 to 0.2 per cent. The viscosity of a 6 per cent solution of cellulose acetate in acetone at 15 deg. C. gave figures varying from 90 to 5, the viscosity of 30 deg. B \acute{e} . glycerine being 100. The free acidity expressed as per cent CH_3COOH varied between 0.01 and 1; ash between 0.8 and 0.13 per cent.

The acetates containing the higher acidity, the greater quantity of ash and of insolubles are the most unstable to heat, decomposition starting at 176 deg. C., whereas for normal acetates decomposition starts at 210 to 215 deg. C., which shows that the industrial product is a mixture of di- and tri-acetate. That this is so can be proved by determining the acetyl percentage by the Barthelemy method of saponification.

The theoretical percentages of CH_3CO are: for di-acetate 34.96 and for tri-acetate 44.79.

A commercial acetate from the Usines du Rhône having the following properties was found to contain 43.08 per cent CH_3CO :

Viscosity at 15 deg. C. (30 deg. B \acute{e} . glycerine = 100) . .	16.5
Insolubles in acetone at 15 deg. C.	0.2 per cent
Free acetic acid	0.005 per cent
Ash	0.18 per cent
Moisture	5.3 per cent
Decomposition starting at	218 deg. C.
Total decomposition at	224 deg. C.

Industrially it is practically impossible to avoid the mixture, because usually only minimum amounts of acetic anhydride are used in the reaction with cellulose.

There is no acetate perfectly pure. The acetic esters being non-crystallizable, the law of mass action (the reciprocal reactions of two substances depend not only on their affinity constants but also on their relative concentration) cannot be applied to the system of the mixture of acid and cellulose acetate due to the total absence of homogeneity. This law applies only when all of the cellulose acetate is in solution.

Cellulose acetates decompose when submitted to vaporization or distillation.

Commercial tri-acetates when heated change aspect slowly between 175 and 220 deg. C. and carbonize between 188 and 270 deg. C.

ESTERIFICATION

Cellulose tri-acetate is obtained by direct acetylation of dry cellulose with acetic anhydride and acid, but as these organic acids, although strong, do not have hydrolyzing power, the hydrolysis is started by introducing in the mixture traces of inorganic acids (H_2SO_4 or H_3PO_4) or compounds giving inorganic acids (zinc chloride, ammonium persulphate, acid potassium sulphate, methylamine sulphate, copper sulphate). It is advisable that the formation of the esters shall be slow, because an energetic hydrolysis has a strong influence on the molecule of cellulose to be esterified.

The acetylation is a bimolecular reaction, expressed by the following equilibrium:

The acetylation is improved by raising the tempera-

ture carefully to a degree which is determined according to the catalyzer used. Thus, for ZnCl_2 , KHSO_4 and ammonium persulphate 80 deg. C. is the most favorable temperature. To absorb the water formed during the reaction and to eliminate it from the esterification it is necessary to use energetic dehydrating agents such as H_2SO_4 , H_3PO_4 or ZnCl_2 .

Equilibrium is reached when the acetylated cellulose is dissolved or nearly dissolved. The mixture is heterogeneous when the cotton fibers are not appreciably changed in appearance; it is homogeneous when the cellulose passes into solution in the acetylating mixture.

In the manufacture of nitrocellulose the esterification is energetic and perfect because nitric acid is a vigorous esterification agent; in the case of cellulose acetates the esterification is slower and the destructive action of the acids on the ester during the acetylation is more profound. In the case of the nitrates, these are insoluble in the nitrating mixture and hence no destructive action takes place, whereas the acetates pass in solution, the acetic esters being soluble in the acetic acid and anhydride. Any process by which this solution could be stopped would be of great technical and economic importance, because it would permit a reduction of the quantity of acetic anhydride necessary for the production of a unit of acetylated cellulose and would give a more regular acetylation, without secondary reactions.

L. Ledebur and many other authors propose to add to the acetylating bath a sufficient quantity of carbon tetrachloride, cellulose acetate not being soluble in a mixture of acetic anhydride, acetic acid and carbon tetrachloride. This process is interesting in that the boiling point of carbon tetrachloride (83 to 84 deg. C.) is lower than that of the acetic anhydride (138 deg. C.) and acetic acid (119 deg. C.) and by fractional distillation the carbon tetrachloride can be recovered.

In an industrial acetylation the carbon tetrachloride is added at the end of the esterification operation to precipitate the cellulose acetate. The precipitate is separated by filtration, centrifuging and drying.

OPERATING CONDITIONS

The main points to be considered in the manufacture of cellulose acetates are:

(1) A careful selection of the materials used. The cellulose, acetic acid and acetic anhydride are to be analyzed before used, so that when needed their proportions may be logically modified to give as uniform as possible final commercial products.

(2) Slow and regular acetylation with a thorough temperature control. It has been proved that the variations in viscosity are a function of the acetylation temperature. For a given process an increase in temperature results in cellulose compounds of lower molecular weight, greater viscosity and lower solubility.

(3) Hydrolysis and ripening should be as uniform as possible and under constant supervision with frequent sampling. The samples should be analyzed for solubility (the solubility in acetone being the measure of acetylation for the tri-acetate), plasticity (the plasticity in warm chloroform being also the measure of acetylation for the tri-acetate). It is also a good plan to make microscopic examinations.

It has been stated previously that cellulose acetates even when manufactured by the same process and similar analytically may possess very different qualities.

These variations may be due to the status of hydrolysis during the treatment of the cellulose, to not sufficiently well-controlled esterification, hydrolysis or ripening, or to defective precipitation and washing.

Samples of cellulose tri-acetate to be considered good have to be very soluble, have a very low percentage of H_2SO_4 , and resist the heat test. The following table gives the analysis of the most commonly used tri-acetates:

	Moisture	Ash	Viscosity*	% Free Acetic Acid	% H_2SO_4	Temp. & Decomposition
Acetate H. Dreyfus of Basel	5.97	0.32	18.9	0.005	0.34	178
Acetate H. Dreyfus of Basel	3.95	0.45	27	0.006	0.53	173
English acetate	4.94	0.42	30.6	0.006	0.90	170
British Cellulose Co.	5.22	0.41	38.2	0.068	0.24	164
Usines du Rhone	4.40	0.40	11.3	0.004	0.21	218
Usines du Rhone	4.96	0.16	10.0	0.01	0.12	226

* Viscosity at 15 deg. C. of 6 g. in 100 g. acetone. (Viscosity of 30 deg. B6. glycerine = 100.)

The presence of sulphuric acid in the tri-acetates is very harmful; it diminishes their solubility because it tends to transform them into di- and mono-acetylated derivatives which are insoluble in the usual tri-acetate solvents. This transformation takes place with the production of free acetic acid, so that the presence of too great a quantity of free acetic acid indicates unfavorable conditions.

METHODS USED FOR THE ACETYLATION OF CELLULOSE BY ACETIC ACID AND ANHYDRIDE

The method of direct acetylation of cellulose by acetic acid and anhydride in the presence of acetyl chloride is no longer used. The two methods now used are:

I. Acetylation of a modified cellulose (hydrocellulose, oxycellulose, viscose).

II. Acetylation of natural cellulose (cotton, paper, etc.).

In these two methods the two distinctive cases to be considered are whether the cellulose is or is not dissolved in the esterifying bath.

ACETYLATION OF A MODIFIED CELLULOSE

The Badische Anilin und Soda Fabrik has taken out a series of patents on the hydrolysis of the cellulose by saturation with dilute sulphuric acid (catalyzer) and the acetylation of the hydrolyzed mass separated from the acidulated water. The two cases to be considered are:

(A) *Acetylation With Solution in the Esterifying Bath.*—100 parts cotton to be acetylated are saturated with a 4 to 5 per cent solution of sulphuric acid for sufficient time, then the cellulose is pressed until it contains twenty parts of the diluted acid. The hydrolyzed cotton is loosened and introduced in a mixture of 400 parts acetic anhydride and 400 parts of acetic acid. The reaction is exothermic and the temperature is to be kept around 40 deg. C. The acetylation is complete when the cellulose is entirely dissolved; the cellulosic ester is then precipitated by water, washed and dried.

(B) *Acetylation Without Solution in the Esterifying Bath.*—100 parts are saturated with a 60 per cent solution of sulphuric acid and pressed until the cotton retains only 10 parts of the acid solution. The resulting hydrolyzed cellulose is placed in contact with 300 parts of acetic anhydride and 1,100 parts benzene (precipitant for cellulose acetate). The acetylation lasts twelve hours, then the temperature is raised and

maintained at 60 to 65 deg. C. on a water bath until a sample indicates an acetate soluble in warm chloroform. The cellulose acetate which has not been dissolved is pressed, neutralized with Na_2CO_3 solution, washed and dried. By this method the cellulose retains the texture and form of the initial fiber.

A French patent (316,500) proposes the use of ortho-, pyro- or meta-phosphoric acids or P_2O_5 as catalyzers for the acetylation of a hydrocellulose or oxycellulose (100 parts) with 400 parts of acetic anhydride containing 1 per cent of the catalyzers mentioned, the temperature being maintained at 50 to 60 deg. C.

The acetates obtained by this process are not very resistant, and it is to be remarked that the less the initial cellulose material has been hydrolyzed the better the cellulose acetate produced.

ACETYLATION OF NATURAL CELLULOSE

The modern method for the preparation of the cellulose acetate is by the acetylation of natural cellulose based on the treatment of cleaned and dried cellulose by acetic acid and anhydride in the presence of a catalyzer. The catalyzers used are H_2SO_4 , $KHSO_4$, $CuSO_4$, methylamine sulphate, ammonium persulphate, $ZnCl_2$, etc., the most commonly used being sulphuric acid. Here also, as in the case of the treatment of a modified cellulose, the acetylation is made with or without solution of the cellulose in the esterifying bath.

(A) *Acetylation With Solution in the Esterifying Bath.*—This method is best outlined by giving the description of the reactions taking place according to

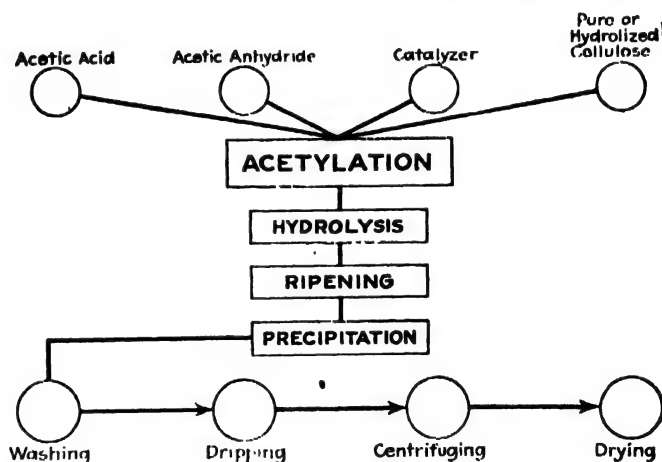

FIG. 1. FLOW SHEET OF THE MANUFACTURE OF CELLULOSE ACETATE

the principles forming the basis of G. W. Miles' American patent 838,350 (1906). The entire operation consists of five phases, the temperature varying with the catalyzer used.

First Phase: Acetylation. Dried cellulose (100 g.) is introduced in a mixture of pure acetic anhydride (270 to 310 g.) and glacial acetic acid (390 to 410 g.), to which is added the catalyzer consisting of 66 deg. B6. sulphuric acid (3 to 5 c.c.). The whole is well mixed and triturated in rocking mixers having two helicoidal blades. The mixer is jacketed so as to permit of temperature control of its contents; the inner wall is of bronze, aluminum or enamel. Capacity of mixer 300 to 600 l. The reaction is exothermic. The temperature is to be maintained at 40 deg. C. until the

mass becomes of homogeneous appearance, when the temperature may be allowed to reach 50 to 65 deg. C. When the temperature starts to drop the mass is heated on a water bath and kept at about 50 deg. until the cellulose is entirely dissolved. This requires from thirty-six to forty-eight hours and even longer. The end of this phase is reached when a sample precipitated by water is soluble in cold chloroform and insoluble in acetone.

Second Phase: Hydrolysis. A mixture of 60 to 65 c.c. water and 60 c.c. acetic acid per 100 g. cellulose is added slowly to the esterifying bath by continuous agitation. During this phase of the operation there must not be any precipitation of cellulose acetate.

Third Phase: Ripening. The mass from the mixer is transferred to similar mixers but of greater capacity and allowed to ripen at 40 to 50 deg. C. for twelve to sixteen hours. During this time hydrolysis takes place uniformly and slowly and the cellulose acetate which was insoluble in acetone becomes gradually soluble while the solubility in cold chloroform diminishes. This ripening results in a greater and more complete division of the cellulose acetate molecule, as can be seen by examining samples at different stages, the product becoming more and more a tri-acetate soluble in acetone, more divided and less granular.

Frequent samples for the determination of viscosity and solubility will indicate the point when the cellulose acetate is of the required quality. The ripening phase is to be guided by the following characteristics:

A product soluble in cold chloroform and insoluble in acetone indicates that the ripening is not complete.

A product insoluble in cold chloroform, plastic in warm chloroform and soluble in acetone indicates that the ripening is complete and the tri-acetate of cellulose is of the desired quality.

If this stage of ripening is passed the product becomes a complex mixture of hydrocellulose acetates which after precipitation is in the form of powder whose solubility and qualities are very variable. If the ripening is carried still further the product obtained is a biose (cellobiose, $C_{12}H_{22}O_{11}$).

Fourth Phase: Precipitation. The acetylated mass is transferred to precipitation vats and precipitated with an excess of cold water to which is added an alkaline carbonate sufficient to neutralize the sulphuric acid used. The whole is stirred mechanically. The acetate is precipitated as a white flocculent mass which is to be washed and neutralized as perfectly and as fast as possible so as to avoid the hydrolyzing action of the sulphuric acid which would give acetates of lower molecular weights, less resistant and susceptible to decomposition during storing.

Fifth Phase: Drying. The neutralized and washed cellulose acetate is placed in drying chambers and maintained at a temperature of 20 to 25 deg. C.

The theoretical efficiency is seldom realized, but with carefully controlled acetylation, hydrolysis and ripening stages, the industrial efficiency of the reaction

$C_6H_{10}O_5 + 3CH_3COOH \rightleftharpoons C_6H_7O_2(OCOCH_3)_3 + 3H_2O$
reaches 83 per cent.

In all the acetylation methods these five phases of the entire operation are to be considered. The temperature and duration of each phase vary with the catalyzer used. Thus: With $ZnCl_2$ the acetylation, hydrolysis and ripening are performed at 65 to 70 deg. C., with

nitrosyl sulphate at 70 deg. C., with ammonium bisulphate at 50 deg. C., with methylamine sulphate or aniline sulphate at 30 to 60 deg. C. and with potassium bisulphate at 80 deg. C.

THE NAAMLOOZE VENNOOTSCHAP CO.'S PROCESS FOR THE PREPARATION OF CELLULOSE TRI-ACETATE

A new method for the preparation of cellulose tri-acetate is that of the Naamlooze Vennootschap Fabriek van Chemische Producten Co. of Holland (French patent 494,832 of June 10, 1919). The principle is to submit the cellulose to a preliminary treatment by which the penetration of the catalyzer into the cellulose fibers is greatly facilitated.

This method can be realized in the following two ways:

1. By the use of glacial acetic acid.
2. By the use of weak acetic anhydride.

(1) *Use of glacial acetic acid.* (a) *Preparatory treatment.* 100 g. cellulose is impregnated with 500 c.c. of glacial acetic acid and 5 g. of 62 to 66 deg. B \acute{e} . sulphuric acid. Let stand for twenty hours at 15 to 20 deg. C. (b) *Acetylation.* Add 500 g. of 80 per cent acetic anhydride, cool to maintain the temperature at 40 deg. C. until a clear solution is obtained. (c) *Hydrolysis and ripening.* After a few hours add 40 to 60 c.c. of 10 per cent sulphuric acid and let ripen for twenty-four hours at 35 deg. C. (d) *Precipitation and drying.* The precipitation is realized by the use of an excess of cold water and the precipitate washed and dried.

(2) *Use of weak acetic anhydride.* When it is desired to use weaker acetic anhydride the operations are as follows:

(a) *Preparatory treatment.* 30 g. of cellulose is impregnated with 300 g. of a mixture of 40 per cent acetic anhydride and 60 per cent acetic acid for sixteen hours at 16 deg. C. (b) *Acetylation.* Raise the temperature to 35 deg. C. with constant stirring until a clear homogeneous mass is obtained. (c) *Hydrolysis and ripening.* Add 18 to 20 c.c. of 10 per cent sulphuric acid solution and let digest for twenty-four hours at 35 deg. C. (d) *Precipitation, washing, drying as in the previous methods.*

(B) *Acetylation Without Solution in the Esterifying Bath.*—A typical example of this method is that forming the subject of Harry S. Mork's American patent 854,374 (1907). The operation is as follows: (a) *Preparatory treatment.* Treat 100 g. of cotton with a mixture of 400 g. of pure acetic acid and 20 g. benzene sulphonic acid for a few hours; the mass is pressed until it contains half of the original liquid and ripened for twelve hours at 15 to 20 deg. C. (b) *Acetylation.* The wet cellulose is esterified by immersion in a bath containing 300 g. of acetic anhydride and 1,200 g. benzol. (c) *Ripening.* The mass is maintained for about eighteen hours at 15 to 20 deg. C. until a sample indicates a product of the desired solubility. (d) *Precipitation, washing and drying as in the previous methods.* The Société Debauge et Cie. (French patent 450,886—1915) uses a similar process with benzene, toluene or carbon tetrachloride as precipitants for the cellulose acetate.

(An article on the Properties and Industrial Uses of Cellulose Acetate will be published in a subsequent issue.)

Failures From Contraction of Welded Straight Piping Solved by Using Welded Bent Piping

An unusual contraction problem arose recently in connection with the pipe welding on fifty-four large gasoline condensers for the Texas Oil Co. Each condenser consists of four large forge-welded drums and seventy lengths of extra heavy 2-in. pipe. The drums are open at one end and flanged so that they may be bolted or riveted together after the pipes are welded in.

The pipe welding is being done by the Oxweld Acetylene Co. at the welding shop of that company's Newark plant. The original plan called for straight piping in line of center between each lateral pair of drums and bent or bowed piping to connect the sides. As the distance between the drums had to be exact to meet the foundation specifications and to insure coincidence of the flanges and bolt or rivet holes of one set

APPLICATION OF WELDED BENT PIPING

of drums with the corresponding points in its mates, the importance of properly handling the contraction problem is at once apparent.

Oxweld engineers recommended the substitution of bent piping for the straight piping noted. The theory as to contraction control was tested on both the straight and the bent pipe. Accordingly a heavy cast-iron jig was made, to which the drums were made fast in the proper position with heavy bolts. The contraction when the straight pipe was used was so powerful that the bolts were sheared off by the pull on the drum, the contractions amounting to several inches. When the bent pipe was used instead of the straight pipe this did not occur, the bent pipe accommodating itself to the contraction so completely that when the drums were removed from the jig they were found to be in correct position, fitting perfectly with the mating pairs.

The application of the bent piping is clearly shown in the accompanying photograph. After the welding, the condensers are tested to a hydraulic pressure of 500 lb. per sq.in. In one of these tests a 3-in. cast-iron cap bolted to one of the drums gave way, but the pipe welds in every instance stood the test without a break or a leak appearing, clearly demonstrating the remarkable strength of the oxy-acetylene welds to resist unusual pressure strains. There are thirty-five pipe welds in each drum and 140 in each complete condenser, a total of 7,560 welds in the fifty-four condensers.

The fifty-four condensers will be used in the distillation plant of the Texas Oil Co. for recovering gasoline from natural gas and crude oil.

Synopsis of Recent Chemical & Metallurgical Literature

The Sugar Situation in France.—The sugar situation in Europe has suffered very much during the war, as can be seen from the following data taken from a study by P. NOTTIN on the French sugar industry before and after the war. (*Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, vol. 132, 1920, pp. 103-108). Thus the European production of 8,179,013 tons of sugar for the fiscal year 1913-14 was reduced to 3,642,664 tons for the fiscal year 1918-19. This decrease in production was more accentuated in France and Belgium and the present conditions in these two countries are far worse than in the other sugar-producing countries, because the greater part of the French and Belgian sugar refineries have been wantonly destroyed.

The following table shows the status of the French sugar industry during the war:

Fiscal Year	Sugar Beet Average Cultivated	Number of Sugar Plants In Operation	Amount of Sugar Produced, Tons
1913-14	515,000	206	717,400
1914-15	531,000	69	302,960
1915-16	186,800	64	135,899
1916-17	201,000	65	185,435
1917-18	187,000	61	200,265
1918-19	169,200	51	110,096

Of the 206 sugar refineries in operation in 1913-14, 145 have been wrecked. Only fifteen of these plants can be repaired; the remaining 130 have had all the machinery and apparatus completely destroyed beyond repair and in ninety plants even the buildings have been demolished. In the four main French sugar-producing departments—Aisne, Nord, Somme and Pas-de-Calais—the number of refineries and their power during 1914 and 1919-1920 were:

Departments	1914 Number of Plants in Operation	Power	1919-1920 Number of Plants in Operation	Power
Aisne	47	19,920	1	200
Nord	38	19,135	1	325
	34	17,250	3	4,400
	25	12,260	6	5,430

Of the 700,000 tons of sugar constituting the average French yearly consumption, the maximum which can now be produced is about 275,000 tons, to which may be added a maximum of 110,000 tons of cane sugar from the French colonies (Guadelupe and Martinique). Although a sugar-exporting country in 1913, France has now to import about half of its needed sugar. It will take years before the French sugar industry will be able to resume its former status.

In spite of European conditions, however, the world's cane sugar industry has flourished during the war. Thus the cane sugar production has increased from 9,821,413 tons in 1913-14 to 12,009,866 tons during 1918-19. Before the war cane sugar constituted 52.6 per cent of the total world production; in 1918-19 this figure was increased to 73.4 per cent.

The beet sugar industry has grown during the last few years in America; the same can be said of Cuba for the same sugar.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Process for Sterilizing Food.—A process for sterilizing food, such as fruit and vegetables and other organic substances, such as starch and gelatine, but especially applicable to milk, consists in heating the substance to be treated while it is exposed to a pressure of one atmosphere or over of some appropriate gas. For milk, air or nitrogen may be used, but pure oxygen is not suitable. It is stated that milk treated by this method at temperatures between 70 and 98 deg. C. lasts less well than milk that has been treated at temperatures either just below 70 or above 98 deg. C., the process last described giving the greatest durability. To cause the milk to retain its odor and taste, rapid oscillations of temperature are produced during the process, either by forcing comparatively cold gas through the highly heated milk, or highly heated gas through comparatively cold milk, the pressure being maintained constant throughout the process by a loaded relief valve. (Br. Pat. 142,169—1919. R. PAPE, Bussum, Holland, June 30, 1920.)

Apparatus for Catalytic Synthesis of Ammonia.—In an apparatus for the catalytic synthesis of ammonia at pressures exceeding 500 atmospheres the removal of the ammonia from the product of the reaction is effected by means of a series of tubes each entering the cata-

lyzer tubes and connected to a cooled receiver, the gases freed from ammonia passing back to the catalyzer tube by a tube surrounding the exit tube, this circulation of gas being induced by the difference in density between the mixture containing ammonia and the mixture freed from ammonia. The apparatus illustrated consists of an outer steel tube T' and an inner metal tube T'' separated by a layer of heat-insulating material; a shorter inner tube T''' surrounded by an electric heating-spiral S extends as far as the plug M , this tube T'' and the portion of tube T'' beyond the plug M being filled with the catalyst. The reacting gases enter by the pipe K and pass first through the annular space surrounding the tube T'' , thereby being heated to the reaction temperature (500-700 deg. C.) and then enter the mass of catalyst. The reaction gases are withdrawn by means of a series of pipes t' , each of which penetrates into the catalyst and is connected to a cooled receiver C in which the ammonia condenses, the residual gas returning to the catalyst tube by pipes t surrounding the pipes t' ;

the pipes t are lagged with heat-insulating material. In a modified construction, the gases enter the catalytic apparatus through a central tube passing through the whole mass of catalyst, the arrangement for withdrawing the ammonia being the same as that described above. (Br. Pat. 142,150—1919. L'AIR LIQUIDE, SOC. ANON, POUR L'EXPLOITATION DES PROCÉDÉS G. CLAUDE, Paris, June 30, 1920.)

Calcium Cyanamide.—In the production of cyanamide from calcium carbide and nitrogen the nitrogen is forced under pressure upward through a furnace

jacket packed with fibrous material such as asbestos, and then downward through the carbide in the furnace. The reaction is started by a heat-absorbing lining to the furnace which has been heated by a previous operation, or by electric resistances in the furnace lining, or by an aluminothermic or similar mixture introduced in a cartridge or container. The apparatus described

consists of an outer shell f , an inner airtight shell d , asbestos or like packing e , between them, brickwork such as magnesia bricks c, c' , and a crucible a . The shell d is secured at the top to an angle-iron h and at the bottom by an asbestos joint g . The crucible has a perforated bottom b upon which is placed a layer of asbestos and/or stout paper, which becomes carbonized; it is provided with lifting hooks v and centering pieces x , and rests upon an annular asbestos packing i . The cover l is lifted by means of a lever m , a valve n being provided for releasing the pressure before lifting the lid. The reaction may be started in the first instance by burning straw inserted through opening u . Nitrogen is supplied by a pipe q , passes through the packing e between the shells d, f , thence through openings y in the brickwork and downwardly through the carbide in the crucible a , and passes through the bottom of the crucible and by passages r in the brickwork to an exit s . Dust is removed by an opening t . The separate crucible a may be dispensed with. Several such furnaces may be connected in series. (Br. Pat. 142,354—1919. A. DUCHEMIN, Paris, June 30, 1920.)

Treating Paraffine Wax to Obtain Fatty Acid.—Paraffine wax, while melted and at a temperature of 100-120 deg. C., is submitted to the action of a blast of air or oxygen over a long period, resulting in the formation of oleic and other fatty acids, resin acids, ceresin, spirits of resin and small quantities of alcohols and aldehydes. To prevent decomposition of the products, the process is stopped when a deep yellow color is produced, corresponding to a 70 per cent conversion of the paraffine wax. A catalyst, such as mercuric oxide, or paraffine wax, which has previously been subjected to the foregoing treatment, may be added. (Br. Pat. 142,507—1919. A. SCHMIDT, Troisdorf, near Cologne, Germany. July 7, 1920.)

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Treating Distiller's Slop.—Slops resulting from the production and separation of alcohol from black strap molasses contain certain carbohydrates which interfere with the satisfactory recovery of glycerine. HARRY P. BASSETT, of Cynthiana, Ky., has found that boiling with lime converts these carbohydrates into salts of the hydroxy-acids of the lactic acid series. Upon acidifying, the latter are decomposed with the formation of aldehydes and acids of the volatile fatty acid series. Of these, formic and acetic acids are present in substantial quantities and may be recovered by distillation. The solution is then treated with a mixture of ferrous and ferric sulphate and made alkaline, thus precipitating the basic iron salts of the fatty acids. The mixture is filtered and the filtrate evaporated until about two-thirds of the potassium salts present have separated out. The decanted liquid contains about 50 per cent glycerine, which may be recovered by steam distillation. (1,344,850 and 1,344,851; June 29, 1920.)

Vanillin.—Guaiacol and formaldehyde are mixed together in molecular proportions and diluted with methanol or ethyl alcohol, and an alcoholic solution of hydrochloric acid and of p-nitrosodimethylaniline in half molecular proportion is added. The mixture is heated for several hours on a water bath, gaseous hydrochloric acid being bubbled through continuously meanwhile.

The resulting products give an excellent yield of vanillin with p-amidodimethylaniline as a byproduct. The formed vanillin may be extracted by treating the product of the reaction after cooling with a dilute caustic soda solution, the alcohol is separated by distillation, and the p-amidodimethylaniline is then extracted with benzene or ether.

The remaining alkaline solution of vanillin is then acidified and extracted with benzene or ether, after which the solvent is distilled, the remaining crude vanillin being then distilled in vacuum and the vanillin, recrystallized in water, separates in crystals having a melting point of 81 deg. C.

The reaction gives a yield of 100 per cent of crude product with respect to the guaiacol used. (1,345,649; ANDRÉ WEISS, of Lyons, France, assignor to Société Chimique des Usines du Phone; July 6, 1920.)

Crystal Production.—A method for the production of large regular crystals, such as Rochelle salt, for use in scientific apparatus utilizing the piezo-electric effect is described by ROY W. MOORE, of Schenectady, N. Y. (1,347,350; assigned to General Electric Co.; July 20, 1920.)

Oxidizing Isoborneol to Camphor.—A process for oxidizing isoborneol to camphor which does not require the presence of a starter or catalyzer is outlined as follows by ROLAND L. ANDREAU, of Wilmington, Del.: A quantity of mixed nitric and sulphuric acids is made, containing the following proportions: 339 kg. of sulphuric acid, 66 deg. Bé., and 253 kg. of nitric acid, 26 deg. Bé., specific gravity 1.22. The mixed acid is introduced into a container, which may be provided with any desired type of stirring device. Thereupon about 1 kg. of isoborneol is added to the mixed acid. Only a small amount of the isoborneol is added in order to avoid having the reaction proceed too violently. If the reaction proceeds too violently the undesirable products,

such as resinous compounds and camphoric acid, will be formed, and the compounds will become subjected to such violent ebullition that they cannot be retained in the vessel. When the temperature has risen to above 40 deg. C., indicating that the reaction has begun, which will usually be after about 15 minutes, additional isoborneol is added gradually and with caution; taking care that the temperature of the mass remains between 35 deg. C. and 40 deg. C. during the reaction, continuing the addition until the entire amount of isoborneol added equals 154 kg. The supernatant liquid, which contains the camphor in the form of a loose addition compound with N.O., is then decanted and run into water, where the camphor precipitates as a solid, and is then washed, centrifuged, dried and purified. In this way a substantially theoretical yield is obtained. (1,347,071; assigned to E. I. du Pont de Nemours & Co.; July 20, 1920.)

Cellulose Acetate.—Many attempts have been made to substitute the sulphuric acid used as contact, or condensing agent, in conjunction with glacial acetic acid and acetic anhydride in the manufacture of cellulose esters, on account of its high splitting action on cellulose. The halogen acetic acids have been suggested, but their action is very slow, even when employed in very large quantity. JOE O. ZDANOWICH, of London, England, has found that when these acids are formed in the acetylating mixture in the presence of cellulose their action is more energetic. Thus 20 g. of cellulose is added to a mixture of 60 c.c. of acetic anhydride and 110 c.c. of glacial acetic acid. While stirring, a current of chlorine gas is introduced, either at ordinary temperature or at 60 to 70 deg. C. After about two hours' time, either at this temperature or at the ordinary temperature, ten or twelve drops of sulphuric acid is introduced and the mixture is stirred until it changes into a clear, colorless, very viscous solution, which can be used for films, artificial silk, varnishes and the like, or can be precipitated, and treated and used in the usual way. (1,347,801; July 27, 1920.)

Electrolytic Pickling Process for Copper.—In order to avoid loss of ductility, copper is often worked while hot and in this state it oxidizes very readily. The removal of the oxide scale by pickling in sulphuric acid produces a solution of copper sulphate, the economical recovery of which presents a problem due to losses by leakage and accidents during operation. JOHN COULSON, of Wilkinsburg, Pa., proposes to make the copper body to be pickled the cathode in an electrolyte of dilute sulphuric acid, a lead-containing tank serving as the anode. The arrangement of the apparatus is such as to permit the articles being treated to be attached to the negative pole of the source of electric current before entering the electrolyte in order to prevent, from the outset, electrolytic action of the current upon the metallic copper. The copper oxide is, however, reduced to metallic copper by nascent hydrogen evolved from the electrolyte at the cathode. This process reduces the oxide very rapidly. In order to recover, from the electrolyte, the copper which is present in the form of copper sulphate, he provides a third or auxiliary electrode which may also be electrically connected to the negative terminal of the source of electrical energy. Copper from the electrolyte is deposited upon this auxiliary electrode and is thus recovered. (1,347,897; assigned to Westinghouse Electric & Mfg. Co.; July 27, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Association of Iron and Steel Electrical Engineers

Following is the program for the fourteenth annual convention of the Association of Iron and Steel Electrical Engineers, to be held at the Hotel Pennsylvania, New York, Sept. 20 to 24:

MONDAY, SEPT. 20

9 a.m.—Registration.

10:30 a.m.—Business session (for members only). Reports of committees. Election of officers.

2 p.m.—Papers: "Practical Education of Steel Mill Electricians," W. A. Cornwell; "Relation of Standardization in Electrical Equipment to Safety," Walter Greenwood.

TUESDAY, SEPT. 21

10 a.m.—Papers: "Power Transmission for Industrial Plants," D. M. Petty; "Underground Transmission," A. L. Freret.

2 p.m.—Excursion.

WEDNESDAY, SEPT. 22

10 a.m.—Papers: "Some Considerations in the Determination of Auxiliary Drives," Gordon Fox; "Report of Electrical Development Committee for 1920, E. S. Jefferies, chairman.

2 p.m.—Papers: "The Reversing Electric Mill Considered From the Standpoint of Tonnage," K. A. Pauly.

7 p.m.—Annual Banquet. Arrangements have been made to accommodate 1,000 guests. Ladies are especially invited.

THURSDAY, SEPT. 23

10 a.m.—Papers: "Centralized Turbine Generating Stations for Steel Mills," T. E. Keating; "Current Limit Reactance," R. H. Keil.

2 p.m.—Papers: "Report of Electric Furnace Committee for 1920," E. T. Moore, chairman.

FRIDAY, SEPT. 24

10 a.m.—Papers: "Standardization Committee Report," W. T. Snyder, chairman.

2 p.m.—Excursion.

Industrial Research on Black Pigments Used in the Rubber Industry

The Rubber Trade Laboratory (235 Plane St., Newark, N. J.) announces that an industrial research will soon be started to determine the importance and relative value of the various black coloring agents used in the rubber industry.

The investigation will include the gas blacks, lamp-black, graphite, bone black and powdered coal, on the one hand, while another series of tests will be made on the pitch hydrocarbons made by treatment of gilsonite, asphaltum, petroleum residues, coal tar and stearine pitch or candle tar. Most of these hydrocarbons have become known in the rubber trade as "mineral rubber," although this is a misnomer.

The purpose of the investigation is to accumulate data which will stimulate the use of these products in

the field of rubber and plastic compounds. All users of these materials are invited to write to Dr. Frederic Dannenrath, director of the laboratory, concerning information they may have on the use of the products. It is known that many users have encountered difficulties in manipulating some of these products, and it is therefore hoped that chemists and superintendents will feel free to send to the Rubber Trade Laboratory such questions as have arisen. Collaborators and consumers are assured that this will not place them under any financial obligation to the laboratory.

Last of Surplus Gas Sold

With the recent sale of 150 tons of phosgene, the Chemical Warfare Service has disposed of practically all of its surplus gases. A sufficient reserve is being kept to be ready for use in case of an emergency. General A. A. Fries, the chief of the Chemical Warfare Service, hopes to be able to carry through a plan which will allow the sale of 25 per cent of the reserve gases each year. The gases sold are to be replaced by new gas manufactured by the Chemical Warfare Service. This will allow manufacture to proceed on a small scale, sufficient to provide training and opportunities to apply improvements. General Fries hopes to get permission to adopt the same procedure as is permitted in the Quartermaster Corps, which allows money obtained from sales of materials to revert to the funds of the corps for repurchase of fresh supplies. At present the receipts from all sales made by the Chemical Warfare Service are paid into the Treasury.

General Fries Announces Policy as to Patents

After careful consideration of the whole subject of patenting processes and devices developed in the Government service, General A. A. Fries, chief of the Chemical Warfare Service, has reached the conclusion that the Government should be entitled without charge to full benefits of such development. The employee responsible for the development would be allowed to take out a patent and reap the full benefits of its use by the public or by other governments.

General Fries points out that whether or not the United States keeps abreast with other nations in the matter of gas research depends on stimulating chemists of the Chemical Warfare Service to do their utmost. By following the policy outlined, he believes the public will obtain all the benefits from the patents that could reasonably be expected, and the inventor will not be denied a handsome reward if his discovery is of sufficient commercial value.

German Government to Release Nitrogen Supplies

According to a cablegram from Berlin, of recent date, it is planned by the government to release 30,000 to 50,000 tons of nitrogen, which has been made by the Haber process from air, to be exported duty free. The prices charged to German domestic fertilizer consumers will be reduced by the receipts of sales made abroad.

To Name Consulting Chemists

Brigadier General Amos A. Fries, head of the Chemical Warfare Service, is having difficulty in obtaining his consulting staff. While these places are honorary, General Fries insists on appointing no one who will not take the time to bring helpful thoughts and suggestions to the service. Connection with a Government bureau in a consulting capacity frequently has degenerated to the point where the bureau confers the honor and hears nothing further from its consulting engineers.

General Fries believes that there are distinguished chemists in the United States who will take an active interest in the affairs of his bureau. In laying the proposition before those who are asked to serve in that capacity, he makes it clear that he will expect frequent suggestions from them. If they will submit problems, he will furnish the young chemists to follow them up.

Prize for Method for Hardness Determination

Sir Robert A. Hadfield has placed in the hands of the Institution of Mechanical Engineers, 11 Great George St., Westminster, London, S. W. 1, England, the sum of £200, the income therefrom to be awarded at the discretion of the Council as a prize for the description of a new and accurate method of determining the hardness of metals, especially of metals of a high degree of hardness.

Competitors should familiarize themselves with the ordinary tests of hardness, such as are described in the Report of the Hardness Tests Research Committee (*Proceedings of the Institution of Mechanical Engineers*, 1916, pp. 677-778). What is desired is the description of a research for or an investigation of some method of accurately determining hardness, suitable for application in metallurgical work in cases in which present methods partially fail.

Recommended Specifications for Green Paint—Semi-Paste and Ready Mixed

Circular 97 of the U. S. Bureau of Standards contains specifications for green paint—semi-paste and ready mixed—with special reference to chrome green paint, either in semi-paste pigment ground in linseed oil or ready mixed. The specification covers the general conditions and the maxima and minima of useful, harmful or neutral constituents and methods of sampling, and the details as to the laboratory examination and analysis. The detailed methods of preparing the reagents to be used are also given. The standard was prepared under the auspices of the Bureau of Standards and submitted to large numbers of representative paint manufacturers, and was also recommended by the United States Interdepartmental Committee on Paint Specification Standardization.

Courses in Chemical Engineering

The Bureau of Education has just issued a leaflet describing "Opportunities for the Study of Engineering at American Higher Institutions." This is prepared to assist foreigners desiring to enter technical collegiate work in the United States, but affords also a valuable list of the institutions in this country where 4-yr. courses in various branches of engineering are conducted. Those where a chemical engineering course is

given, leading to a degree, generally Bachelor of Science in Chemical Engineering, are shown in the following table, together with a statement of the total engineering enrollment of the institution—i.e., the enrollment including civil, electrical, mechanical and others, as well as chemical engineering. However, this list does not include institutions where there are given chemical courses not classed as chemical engineering:

Institution	Total Engineering Enrollment
Alabama Polytechnic Institute, Auburn, Ala.....	543
University of Alabama, University, Ala.....	301
University of Arkansas, Fayetteville, Ark.....	177

Chemical Warfare Display Interests Public

The chemical warfare display, which was a part of the so-called shows given by the First Division on its journey from Camp Taylor, Ky., to its new home at Camp Dix, N.J., proved to be the most attractive feature of these entertainments. The use of colored smokes, signal rockets and flame throwers gave the public its first opportunity to see how chemical warfare is conducted. Stokes mortars were used to throw phosphorus and thermit bombs. This feature of the entertainment also proved very interesting to the crowds who watched the maneuvers.

War on Rats With Poison Gas

Rat extermination by the use of the poison gases of warfare is believed to be feasible under certain conditions, as a result of experiments conducted by the Chemical Warfare Service. The experiments were undertaken at the request of authorities at Gulf ports, where the occurrence of bubonic plague has made rat extermination imperative.

In one of the experiments a small cylinder of a mixture containing 30 per cent phosgene and 70 per cent chlorine gases was permitted to escape so as to spread over an area of 900 sq.ft. in which there were fifteen rats. In fifteen minutes the phosgene had been dissipated and in thirty minutes the chlorine could no longer be detected. All of the rats in the area were dead. The cost of the gas was 40c. and in thirty minutes the area could be frequented with entire safety by human beings.

As a result of this and other experiments, it is believed that an important new use has been found for these war gases. The fact that they are heavy and sink into depressions under docks and into cellars, sewers and other places which harbor rats is expected to solve the most serious problem that has confronted rat extermination by the methods heretofore used.

The use of irritating gases in breaking up crow roosts in the forest reserves also is being tried by the Forest Service. The existence of these roosts frequently makes it almost impossible to cultivate agricultural lands in their vicinity. The crows are very persistent in clinging to their established nesting places. It is believed that war gases can be used effectively in combating that pest. Experiments are also in progress looking to the use of gases in fighting grasshoppers and locusts.

Authorized to Buy German Dyes

The Government has decided to exercise its option on German impounded stocks of dyestuffs and has authorized the Textile Alliance, Inc., to purchase these stocks in the interest of the American consumer. The full official statement, issued by the War Trade Board Section of the Department of State, is as follows:

The United States Government, through the War Trade Board Section of the Department of State, has, in the interest of the people of the United States, authorized the Textile Alliance, Inc., of New York City, to undertake, *without profit to itself*, the following action in connection with Reparation dyes:

(1) To purchase certain dyes, being the final apportionment of impounded stocks covered by inventories of German manufacturers as of Aug. 30, Sept. 5, 19 and 27, 1919, in order that certain dyes which are not manufactured in this country and which are included in these impounded stocks might not be lost to the United States with detriment to American interests.

(2) To purchase dyes from the present existing stocks manufactured by Germany between the dates of Feb. 1, 1920, and June 30, 1920, both inclusive, in order that certain dyes which are not manufactured in this country and which are included in these stocks might not be lost to the United States with detriment to American interests.

(3) If found to be necessary and advisable to purchase such dyes as may be required and ordered through it by American consumers from future daily production of German manufacturers for the four and one-half year period commencing July 1, 1920.

(4) The authority of the Textile Alliance, Inc., to resell to American consumers the dyes acquired as above provided is subject to strict provisions regarding selling price and manner of sale for the purpose of insuring fair and equal treatment to all consumers who may wish to avail themselves of the opportunity offered.

The Government has decided to exercise its option upon German impounded stocks and has authorized the Textile Alliance, Inc., to purchase these stocks in the interest of the American consumer. Under existing regulations of the War Trade Board Section no dyes from these stocks may be imported by the Textile Alliance, Inc., which are either manufactured here or for which suitable substitutes are manufactured here on reasonable terms as to price, quality and production. No consumer will be allowed to receive more than a six months' supply of any dye at any one period from this source. Practically the same understanding is in effect regarding the daily production of the German factories from Feb. 1 to July 30, 1920.

Regarding the subject of future daily production, the Department of State has received information which would indicate that for some time to come the German factories will not be in a position to supply all expected requirements of the Allied and Associated countries and to fill Government orders emanating from these sources. If these indications are correct it would appear that unless this Government indicated a desire to exercise its option on future daily production and should render available machinery which would make it possible for American consumers, if they so desire, to obtain colors from this source, the American consumer might not be able to get such German dyes as he required. The consumer should clearly understand that he is not obligated or even advised to place orders through the machinery made available by the Government. If he believes that German dyes may be obtained from unofficial sources he may, subject to the then existing import regulations, either order such dyes as he needs direct from the German manufacturer or through such agent or agency as he may designate.

If the consumer, however, cannot obtain or believes he cannot obtain dyes by other means the Government can exercise its option on the subsequent daily production of the German factories and the Textile Alliance, Inc., can transmit his orders for purchase from official sources.

Experiment With Steel Plate for Canning Purposes

In an effort to determine the best type of base steel plate for use in making tinplate for canning purposes, the chemists of the American Canners' Association are directing an extensive series of experiments, in which they have the co-operation of the American Can Co. and the Granite City Enamel & Stamping Co.

Tests are being made under commercial conditions of the effects of fruit acids on the various types of steel plate. Previous experiments have shown that the weight of tin with which the steel is coated makes slight difference in the resistance of the can to the corrosion of the acids.

Experiments are being made, among others, with a copper-bearing plate killed with silicon, and with titanium-bearing plate.

In this connection, attention is called to the fact that the amount of tin which will produce a toxic effect is not well established. The tin which is dissolved into the contents of a can of acid-bearing food is for the most part in an insoluble condition and probably is not absorbed by the system.

Water Conservation Committee of Engineering Council Offers Services to Power Commission

The water conservation committee of Engineering Council has offered its services to the Federal Power Commission in an advisory capacity on technical matters. Calvert Townley is the chairman of the committee. Other members are Charles T. Main, H. Hobart Porter, M. O. Leighton, Allen Hazen, Arthur P. Davis, Arthur E. Morgan and F. W. Scheidenhelm.

Civil Service Examinations

The United States Civil Service Commission announces open competitive examinations to fill various vacancies in the departments as listed below:

Assistant examiner, Patent Office.
Metallurgical laboratorian.
Laboratory aid.
Laboratory assistant, intermediate grade, \$1,080 a year.
Laboratory assistant, junior grade, \$1,000 a year.
Senior aid, \$900 a year.
Associate physicist qualified in physical metallurgy, \$2,000-\$2,800.
Assistant physicist qualified in physical metallurgy, \$1,400-\$1,800.
Assistant metallurgist (Bureau of Mines), \$2,000-\$3,000.
Catalytical chemist, \$3,000-\$4,000 a year.
Assistant catalytical chemist, \$2,000-\$3,000 a year.
Junior catalytical chemist, \$1,600-\$2,000 a year.
Chemist, \$3,000-\$4,000 a year.
Associate chemist, \$2,000-\$3,000 a year.

Further information may be had by writing to the Civil Service Commission, Washington, D. C.

Old Hickory Powder Plant Bids Postponed

The Director of Sales of the War Department announces that the date for receiving bids for the Old Hickory powder plant, near Nashville, Tenn., has been postponed from Sept. 2 to Sept. 30. This postponement was found necessary because of the large number of inquiries received and the magnitude of the proposition.

Old Hickory, which is a great modern plant and industrial town, was constructed for the manufacture of smokeless powder and explosives, but its several units are readily adaptable to many industries including chemical, rubber goods, such as auto tires; pulp and paper mills, sugar refinery, coking and coke byproducts, food, both evaporated and concentrated; iron and steel foundries, fibrated products, such as asphaltum shingles; aluminum, wood box or refrigerator manufacture, cellulose and photographic film manufacturing and a number of other minor industries, such as an ice plant or cold-storage warehouse.

Lead and Zinc Experiment Station

Lead and zinc problems will be studied at a new Bureau of Mines mining experiment station, which probably will be located at Rolla, Mo. The exact problems which will be taken up at the new station will not be determined until after a conference in St. Louis on Oct. 9 between officials of the bureau and representatives of the lead and zinc industries interested.

The laboratories probably will be located at Rolla, but the business office of the station will be in St. Louis. The name of the station will be the Mississippi Valley Experiment Station. At this writing the Secretary of the Interior has not approved the location of the station, but it is regarded as practically certain that he will have no objection to the selection of Rolla as a site for its laboratories.

C. W. S. Needs \$10,000,000 Appropriation

Fully \$10,000,000 will be required during the next fiscal year to carry on the work of the Chemical Warfare Service on a scale commensurate with the needs of the national defense, in the opinion of chemists who are following the work of the Service. Of that amount it will be advisable, it is estimated, to expend as much as \$2,000,000 for research.

C. W. S. Will Need More Officers

The need of the Chemical Warfare Service in the matter of officers will not be met when the results of the recent examination for commissions are announced. Although more than 200 appeared for the examination, a considerable number failed to pass the physical examination or were disqualified for other reasons. Only about 100 completed the examination. It is certain that a considerable percentage will fail to make the requisite grades. The results of the examination have not been announced but, judging from similar examinations which have been held in the past, those failing to make passing grades vary from 60 to 80 per cent. Ninety-five officers are needed for duty with the Chemical Warfare Service. A very high standard has been required in the examinations.

Personal

A. N. JOHNSON will leave the Portland Cement Association Oct. 1 to take up new duties as dean of the Engineering School and director of engineering research at the University of Maryland, College Park, Md.

PAUL D. V. MANNING has joined the chemical staff of the International Coal Products Co. Newark, N. J. He formerly was with the Chile Exploration Co.

MORRIS METCALF has been appointed president and a director of the International Steel Corporation, 51 Chambers St. N. Y., a subsidiary of the American International Corporation.

KENNETH P. MONROE has resigned as chemist in the color laboratory, United States Bureau of Chemistry, Washington, to accept a research position in the Jackson Laboratory of E. I. du Pont de Nemours & Co., Wilmington, Del.

Dr. R. B. MOORE, chief chemist of the Bureau of Mines, has returned to Washington after an extended trip to the Western experiment stations of the Bureau of Mines.

Dr. E. F. NORTHUP has resigned his professorship at Princeton University to devote his entire time to the business of the Ajax Electrothermic Corporation, Trenton, N. J.

H. B. PULSIFER, who was formerly professor of metallurgy at the Montana School of Mines and state metallurgist, will be an assistant professor of metallurgy at Lehigh University, Bethlehem, Pa., commencing with the academic year 1920-21.

DAVID B. REGER, of Morgantown, W. Va., is on leave of absence from the West Virginia Geological Survey for the next few months and will devote that time to consulting work in petroleum and coal. He has just completed a month's trip to the prospective oil fields of Montana.

HARRY B. RIFFENBURG, formerly assistant professor of chemistry and chemical engineering at the Agricultural and Mechanical College of Texas, resigned on Sept. 1 to accept a position as junior chemist in the quality of water division of the water resources branch of the U. S. Geological Survey, Washington D. C.

Dr. LUDWIK SILBERSTEIN, formerly of Adam Hilger, Ltd., London, is now associated with the research laboratory staff of the Eastman Kodak Co. Dr. Silberstein is known for his mathematical papers dealing with electro-magnetism, optics, theory of relativity, projective geometry, spectrum theory, etc.

F. L. STACK has left the Cia. de Santa Gertrudi at Pachuca, Mexico, to join the staff of the Chile Exploration Co. in New York.

Dr. WALTER F. TAGGART, for many years professor of organic chemistry at the University of Pennsylvania, has been elected to succeed Dr. Edgar Fahs Smith, who resigned last June as Blanchard professor of chemistry at

that institution. Prof. Taggart is now head of the chemical department of the university.

G. M. WILLIAMS, who has been for a number of years a specialist in the cement investigations of the Bureau of Standards, has resigned to accept an assistant professorship in civil engineering at the University of Saskatchewan. Mr. Williams has been particularly engaged in the work of cement protection in regions where alkali waters prevail, having had an active part in the joint investigations of the Reclamation Service, the Department of Agriculture and the Bureau of Standards. It is expected that the Canadian work of this sort which is under way will receive Mr. Williams' active attention for some time to come, in connection with his university activities.

Book Reviews

SCIENCE AND LIFE. Aberdeen addresses by *Frederick Soddy*, M. A., F. R. S.: Dr. Lee's professor of inorganic and physical chemistry, University of Oxford; lately professor of chemistry, University of Aberdeen. 229 pp. New York: Dutton & Co., 1920.

This book is a collection of articles published and addresses made during Prof. Soddy's incumbency of the chair of chemistry at Aberdeen, and it includes the following subjects: Chemistry and Life; Chemistry and National Prosperity; Science and the State; The Future of Science and What Bars the Way; The Evolution of Matter; The Conception of the Chemical Element as Enlarged by the Study of Radioactive Change; Matter, Energy, Consciousness and Spirit; To the New Launch and the Ideals of a Science School. It concludes with an appendix in which the method of administering the Carnegie Trust for the universities of Scotland is subjected to fearless and lively criticism, and a report of the controversy that followed it.

The several essays are rather loosely put together, and there is a slight measure of repetition in them; but this is no fault. Prof. Soddy is a believer in the mission of science; many of the addresses were made during the war, and he spoke from the very depths of his soul, with no effort to hide the emotion which prompted him to issue his call. He tells with marked eloquence the gifts that science has made to humanity, and then he asks what we have done with these gifts. "The strong," he says, "have fed and grown fat upon a large and ever larger share of the manna (from science). Initial slight differences of strength and sagacity have become so emphasized by the virile stream that the more successful are becoming monstrously so, and the unsuccessful less able to secure a full meal than before the shower began." This, it would seem, might be the beginning of radical political propaganda, but it is not. The burden of his complaint is not against political conditions; these do not seem to worry him. His complaint is that we do not know enough; that our education is faulty. He blames our reactionary method of education. "Is there," he asks, "a single practical branch of human thought or knowledge which has been left untouched; nay, more, which has not been altered to its very foundations by the progress of science?" And the reply is, "The education of those to whom, for the most part, is entrusted the happiness and the destiny of nations ceases where it should begin!" He insists that science must not only be taught, but understood, if we are to meet the great obligations of the future.

"The wealth of a country," he says, "is in its matter and energy—matter, the passive resister that in the raw state will not do anything you want it to do; and energy, both animate and inanimate, which is forever trying to do what you do not want it to do, and needs to be controlled. So man found the world, and so, largely till the beginning of the last century, he left it, moralizing and philosophizing eternally about himself and leaving a vast legacy of these elegant accumulations for the 'education' of his children." And he declares we must break the entail of dead languages.

"Let us glance at the change that has come over the

world with regard to the relations of man to energy and matter. Instead of being between the two as between a steam hammer and an anvil, man has climbed to the controlling gear and has his hand upon the valve. And the hands on this valve are the hands of the chemist and the physicist, and their executive officer, the engineer."

He recognizes the possibility of developing power from breaking down atoms of the heavier elements and he even hopes that with the immense capacity for use and destruction that will come with this achievement it may not be too soon at hand. For we are not ready to wield such power. We are not yet good enough.

The book is of special interest to men of science, because it brings out their immense burden of responsibility. He says that the elevation of human ideals and the inspiration of character has not progressed to keep pace with the growth of physical power at hand. For power is everything. We live on it, developing it very much as a steam engine develops it from fuel. When we get our power in immeasurable quantities we shall have such capacity to do harm that it may be we are better off without it. It would be well also for the educator to read the book. If he is a classicist it may worry him, but he will be unable to resist the demand to ask himself whether he is making his own work worth while.

The chapters on radioactivity are beautifully written, and, coming from Prof. Soddy, are authoritative.

ELLWOOD HENDRICK.

SURVEYING. By *W. Norman Thomas*. 536 pp. 18 chapters. London: Edward Arnold; New York: Longmans, Green & Co.

The latest surveying science as practiced in England is amply presented. While this text is not in the same class from an engineering viewpoint as the leading standard American treatises, nevertheless it can be read with profit by our surveyors who have the desire to import new ideas and incorporate them in their practice.

WALLACE SAVAGE.

Current Market Reports

The Iron and Steel Market

Pittsburgh, Sept. 10, 1920.

It has become obvious that the peak has been passed in iron and steel demand and in prices, but no early cessation is to be expected in furnace and mill activity, nor are prices likely to decline in the near future.

Apparently it required the passing of the midsummer period to show conclusively that the market lacked fundamental strength. July and August are always very dull months in the iron and steel markets, hence the dullness in the bimonthly period just ended attracted much less attention than it would have attracted at any other time in the year. If the season of year were the governing influence, the passing of time would have brought an increase in activity, but the actual condition is one of stagnation.

EFFECT OF NORMAL RAIL TRAFFIC RESTORATION

A question that was a puzzling one a few weeks ago has now been answered, what would be the effect upon business, and upon steel demand in particular, of a restoration of rail traffic conditions to something like a normal basis, whether that would stimulate business by making it easier to do business, to produce and consume, or would put a damper on business by causing consumers to depend more upon their stocks. It may be difficult to establish precisely the connection between the improvement in rail traffic conditions and the present state of the iron and steel markets, if indeed there is any important connection, but at any rate two things have occurred, the rail situation has become almost normal and the iron and steel markets have become patently dull.

The condition is simply one of abstention from buying. Consumers are content with the material that is already due them on purchases and are indisposed to make additional commitments. Here and there some demand exists for early deliveries, but the total tonnage is not large and the material is wanted simply to "piece out."

CANCELLATIONS OF STEEL ORDERS

Much reference is made to cancellations that have occurred, or are likely to occur, of steel orders. The situation in this respect is much like what has obtained in the past after a great market movement. There are cancellations, but they involve no large tonnage in proportion to the total on mill order books. Each arises from some special condition obtaining with the buyer, so that the cancellations that have occurred are by no means typical or illustrative of a general condition. In the main the material that has been ordered is actually required to carry out engagements the buyer has made.

NO DECLINING TENDENCY IN PRICES

There is no general declining tendency in prices of either pig iron or steel products. Some developments might be cited as indicating declines, but they would not be a real criterion. There have been several different markets, first the Steel Corporation market, at the Industrial Board prices that became effective March 21, 1919, and then several different markets among the independents. Some independents sold to regular customers at prices that have changed scarcely at all since the advance culminated early in the year. Other independents sold at approximately all they could secure, but only to regular customers. Others still made no distinction between strangers and those who had been regular customers. In this last-named market some declines might be found, but that is of no consequence. The producers that have maintained more or less steady prices are adhering still to those prices and possibly they are a shade stiffer than they were.

Except as to one matter, the whole steel market presents an appearance strikingly similar to conditions that have obtained at various times in the past when there had been an active buying movement with advancing prices. There is the same quiet market, the same maintenance of prices and the same willingness of buyers to accept deliveries on old contracts while they will not make additional commitments. The one exceptional feature is that the United States Steel Corporation, which makes about 44 per cent of all the steel, has no connection with the situation. It did not advance prices, and it is sold, in proportion to capacity, probably at least twice as far as are the independents. The corporation experiences few if any cancellations.

Just as has been the case at similar junctures in the past, the mills are indisposed to reduce their prices. Little if any business would be attracted, and the filling of the business now on books would be jeopardized more or less.

OUTLOOK IS FOR FULL OPERATION TO END OF YEAR

The only important question at this time is how long the momentum will carry the situation. The mills are operating as full as they can and have been shipping not only their current output but much of the material accumulated in the four months April to July, when it was impossible, on account of rail traffic conditions, to ship all the output. The various experiences of the past have been that a stagnant market is not followed quickly by lessened production. The mills run on their orders and the momentum carries them for quite a while. At the moment the outlook is that there will be substantially full operation to the end of the year, and quite possibly through the winter. The prices of independents may not decline for months, and when they do decline they will probably decline rapidly.

THE PIG IRON MARKET

It has required only a very short time to make it plain that the recent advance in pig iron in various districts was not justified from any conservative viewpoint. Pig iron, being made to sell, is not benefited by a paper price, and the \$50 level to which pig iron was pushed in several

districts is a price on paper but a price at which little iron has been sold or is likely to be sold. Pig iron was already too high in relation to steel products and in relation to pre-war prices. Apart from that, some developments may be mentioned. The production of merchant pig iron increased by about 7 per cent from July to August, and to a rate that has been exceeded for only a few weeks at any time in a year and a half, while there are some idle furnaces ready to go into blast if they can secure coke, but they require the coke at a price much below that at which there would be left a good margin of profit on pig iron sold at \$50. Another development is that two districts, Chicago and Birmingham, have not followed the advance. Chicago remaining at \$46 and Birmingham at \$42. That is not because the producers in those districts were unable to force their prices up, but because their judgment was that it was best not to do so. Even with the stiff advance in freight rates Birmingham iron could get into Pittsburgh and beat valley iron by over \$2 in the delivered price, whereas in the past few years Birmingham iron has rarely been able to get into Pittsburgh.

Two other developments bearing upon the future of pig iron prices may be mentioned. The Steel Corporation has some pig iron production at Milwaukee that is sold as merchant iron, and the corporation has just set a price of \$39, furnace, on its fourth quarter deliveries, these being confined, of course, to regular customers. The corporation also has some merchant production in the Birmingham district, on which its price has not gone above \$38, Birmingham, and it is now announced that on Oct. 1 two more furnaces will be put into the merchant class, as their output will no longer be needed for the steel works.

The Chemical and Allied Industrial Markets

New York, Sept. 10, 1920.

Two weeks have gone by since the last market report in these pages, yet conditions have changed but little. Prices are no firmer; in some lines there has been a decline, while buying is practically at a standstill.

Spot supplies are mostly of those items which have been less active than the others in the past, and holders are consequently still finding difficulty in disposing of this material even with the concessions being granted. *Caustic potash* still remains firm around 28c. per lb., with very little obtainable for spot demand and producers pretty well sold up for some time to come. On the other hand, *caustic soda* and *soda ash* are somewhat weaker. Although former prices of \$5.60@\$6 per cwt. for the former and \$3.20@\$3.60 per cwt. for both grades of the latter still prevail, nevertheless those who do not seem to agree with these prices are remaining quiet. *Copperas* and *barium chloride*, two recently active items on the list, are now in better supply and quantities of the former can be obtained around \$2 per cwt., although \$2.25 seems to be the more average price, while *barium chloride* has come to \$130, compared with a former low level of \$150 per ton. *Arsenic* continues rather dull, with very little business recorded, at 14@16c. per lb. for the white grade and 17@19c. for the red. *Bleaching powder* maintains the firm tone which has been noticed for some time and is obtainable only in small lots at \$7@7.50 per cwt., which is 50c. better than the last listing. The intention of the comment on the above items is to indicate that tendency of chemical prices at present is not upward.

COAL-TAR PRODUCTS

All that has been said in the previous paragraph applies to this market and to avoid repetition it is sufficient to say that the condition is little more acute in this case. There is small room for doubt that the crudes would be more active if they were in better supply, as the demand for these continues brisk, but producers are handicapped under present labor conditions and are contracted for a considerable length of time in advance. The opposite is true of the intermediates. Supplies are greater than requirements at present and buyers, realizing this situation, are holding out for lower prices. Among the intermediates to come down during the period was *dimethylaniline*, which dropped to

80@90c., compared with the former quotation of \$1@1.05 per lb. *Beta naphthol*, technical, was also affected by this inactivity and dropped off 5c. per lb., from 85@95c. to the present listing of 80@85c. per lb. In line with the others *paranitraniline* is weaker, being available at \$1.10@1.15 per lb., with the possibility of still lower prices in large quantities, compared with the previous firm quotation of \$1.10@1.20 per lb.

NAVAL STORES

Turpentine started on the decline about a week back and has been dropping steadily since then. Current quotations range around \$1.49, against the previous quotation of \$1.55 per gal. The slackening of foreign demand is responsible for this condition, which it seems will prevail a while at least. Savannah, which influences the local market, is quoted at \$1.48 and is on the decline, being supported by the local buying, which in itself is not very heavy.

VEGETABLE OILS

This market is very much weaker than it was two weeks ago. No interest is being displayed by buyers even at the present low levels. Crushers are stocked up and are unable to dispose of their supplies. Noticeable declines occurred in *chinawood oil* in barrels, f. o. b. Pacific coast, listed at 14½@16c. per lb. *Linseed* is also considerably weaker, being quoted at \$1.22 per gal. as the general quotation, while it is rumored sales have gone as low as \$1.10 per gal., for which level buyers seem to be waiting.

The Baltimore Market

Baltimore, Md., Sept. 8, 1920.

Purchasing of raw fertilizer materials on the local market for the past few weeks has been practically at a standstill. This has been due in part to the manufacturers' inability to get cars for shipping the finished products, also the general weaker tone in the market for many raw materials.

Now that the new freight rates have gone into effect, the local trade generally expects a greater supply of cars and a consequent speedier movement of mixed goods and raw materials. It is generally felt that the bearish condition is due to the tight money situation, rather than an excess supply or lack of demand.

Since our last letter a fire occurred at the plant of the Standard Guano Co., Curtis Bay, this city, which resulted practically in the complete loss of the bone mill, tankage house and a large stock of raw materials; this loss has been estimated at \$250,000. Fortunately, the acid plant and adjoining properties were uninjured.

ACID PHOSPHATE

Acid phosphate continues to be strong in demand, with the market showing no weakness. Bulk acid phosphate, run of pile, is being nominally quoted at \$20 per ton, basis 16 per cent A. P. A., f. o. b. Baltimore. Sales for spot parcels have been reported at somewhat higher figures. A number of recent inquiries for spot goods have failed to result in business because of the sellers' inability to get cars for shipment. The labor situation at the mines does not seem to have been appreciably improved, and as a consequence the raw rock shortage continues and a generally firm price for acid phosphate for spring is expected.

NITRATE OF SODA

The nitrate of soda market for nearby deliveries continues to work lower. Spot parcels, Southern ports, are being offered at \$3.65, and in some cases sellers are soliciting bids. Spot parcels may be had locally around \$3.75, and it is believed that delivery up to Jan. 1 could be had around the same figure. Importers are quoting nominal for forward deliveries at \$3.80 Atlantic ports. Reselling of nitrate by Japan has been effected on rather a large scale; purchases made by local manufacturers were on a basis of ex vessel Pacific port; the prices paid, however, figured closely in line with the quotations given here.

POTASH

The demand for potash on the local market is quite limited at this time, and a number of resale lots of various

grades of foreign salts are being offered for spot and nearby deliveries. Nominal quotations for August, September, October, arrival Atlantic ports, are as follows: Muriate potash, \$2.35 per unit; manure salts and kainit, \$1.95@2.05 per unit K₂O; for November forward sellers are generally asking a premium of 10 to 15c. per unit. Domestic potash is being quoted nominally at \$2.25 per unit f. o. b. mines for delivery November forward.

SULPHATE OF AMMONIA

A number of resale parcels of sulphate of ammonia from Japan are still in evidence. The last offerings noted were at \$5.55 per cwt., bulk, basis Baltimore rate of freight.

FISH SCRAP

Menhaden fishing on the Chesapeake Bay during the past few weeks has been generally poor. The fish have been running uniformly low in oil, and as a consequence the fish factories are greatly disappointed in the results obtained so far this season. The production of scrap has been sold ahead at a uniform price of \$7.50 and 10c. f. o. b. factories.

Due to the shortage in production and the steady demand for scrap, no weakening in this market is expected for the immediate present.

The Chicago Market

Chicago, Sept. 8, 1920.

In practically all lines the local chemical market is apparently in the doldrums. Instead of being surprised and disappointed at this condition, all parties concerned are sufficient students of economy to realize that it is inevitable and are complacent in the knowledge that they have so disposed their resources as to be able to get through this stagnant period with no real financial difficulty.

Sharp observers early in the spring saw that in the flood of orders being booked in all manufacturing lines a great many duplications and inflations were creeping into the swollen back order files, and that cancellations and a scaling down of orders must necessarily occur. The present slackness of trade is felt to be the natural reaction from the super-prosperity of the spring season, and as the chemical industry furnishes the basic raw materials in many lines, this slackness is naturally most keenly evident in the chemical trade.

One good feature of the current depression is the elimination of the numerous "vest pocket manipulators," dealers in chemicals whose stock in trade consisted of a list of obtainable supplies, whose participation in the trade tended only to increase the difficulties of legitimate buyers and sellers, to the profit of the speculators alone.

All consumers are today marking time—buying only sufficient materials to keep production up to the necessary mark, and in many lines that mark has been placed considerably lower than it was a few weeks ago. The price recessions on many lines are sharp, but quotations are still above what is felt to be the real intrinsic value of the commodities concerned, so that lower levels may be expected before business again strikes a normal stride.

HEAVY CHEMICALS

Trading is negligible. Those items which are firmly held in first hands remain steady in price, but those of which any great supply is in the hands of re-sellers are uncertain. With the exception of bleaching powder, the alkalis are showing little activity and are not strongly held. *Bleaching powder*, being very scarce and in need by the users, is worth whatever the customer can be compelled to pay. Small lots are being sold at prices ranging from 7@8c. per lb *Caustic soda*, under slack demand and improved supply, is offered at 5c. per lb. on spot, and it is probable some shading is being indulged in. *Soda ash* and *sal soda* are in a similar position, current quotations being slightly lower at 5c. and 2c. per lb., respectively, for sales from stock. No great activity can be expected in this class of material until makers announce contract prices for next spring.

But few items of interest are noted in the remainder of

the heavy chemical line. *Salt cake* is not available in sufficient quantity to supply all demands, though contracts are being filled. Trades in spot goods are running up to \$50 a ton in car lots. *Arsenic*, as indicated in the last report, is off a cent to 14c. per lb. on the *white* and 18@18½c. per lb. on the *red*. *Copper sulphate* (blue vitriol) is firm at 9c. in cars and *copper carbonate* is still quoted at 27c. by both first and second hands with but few transactions noted.

Alcohols of all grades are unchanged in price while *formaldehyde*, under influence of a strong Eastern market, is quoted at 55c., with no great amount of sales. Holders and users of *glycerine* seem to differ in their opinion as to its worth, with a poor market at 28c. for c.p. grade as the result.

COAL-TAR PRODUCTS

* Retrenchments in the textile industry are having their effect in keeping interest in color products at a low ebb. With the exception of *aniline oil* and *aniline salt*, no fluctuations of moment have been noted. These two items, in a very weak market, registered further declines and are easily obtainable at 25@26c. for the oil and 35½@36c. for the salts. Improved demand for oil has brought quotations up to 28c., but the salt continues as low as or even lower than before. Predictions of higher prices are heard, but it is difficult to find any facts to substantiate them. Prices on coal-tar crudes and acids are level, but with little trading being indulged in.

VEGETABLE OILS

Trade in all items of the list is very dull. Soap makers, paint makers and consumers of edible oils alike express themselves as satisfied to produce only sufficient finished product to fill actual orders and in many instances have sufficient raw material on hand to supply their needs for some time to come. In the face of a falling market no one can find justification for keeping up a heavy reserve stock, hence actual trading is at an exceedingly low level. *Cottonseed oil* last week reached a sufficiently low level to invite some investment. Prices are therefore fairly firm at 10½@11½c. per lb. on prime summer yellow and 15½@15¾c. per lb. on refined, deodorized. *Red oil*, under pressure of a lack of buyers, is given a nominal quotation of 13@13½c. with but few sales recorded, and *corn oil* excites no interest at the current quotation of 9c. Some buying by consumers is noted in *coconut oil* at 13@13½c. per lb. in sellers tanks, f. o. b. coast, and at 16@16½c. f. o. b. Chicago for Manila grade. The refined grade is 1c. higher. But little interest is displayed in *soya bean oil*, current transactions being reported at the unchanged price of 9½c. per lb. f. o. b. coast.

Linseed oil remains of uncertain value, the effect of low quotations on futures being very keenly felt. Holders of spot stocks decline to do business at less than \$1.40 per gal., so that few actual transactions are being made.

Offers of *linseed oil* for future delivery at low prices have affected spots to such an extent that current quotation in tank cars, f. o. b. Chicago, is \$1.15 per gallon. In barrels the price is 7c. higher. As futures are offered at still lower figures, the low prices have failed to induce heavy buying.

NAVAL STORES

Gradually falling prices, accompanied by a practice of hand-to-mouth buying by principal consumers, has made the local market in *turpentine* and *rosin* weak. *Turpentine*, under a plentiful supply, is off to \$1.48@1.55 for barrels in car load lots, f. o. b. Chicago. In quantities of from one to twenty barrels, quotation is 7c. higher. The prevailing weakness has also affected *rosins*, which three weeks ago were quoted at \$16 per barrel in l. c. l. quantities on all grades. Today \$14@14.25 is quoted on WW grade with darker grades from 25c. to 35c. cheaper. Owing to insistent demand, market on pine oil remains firm at \$1.90 per gal. This is one item of the line that needs no stimulation of foreign buying to maintain strength, as the best efforts of the producers are inadequate to supply the needs of our own country.

Brass, heavy	cents per lb.	9.50
Brass, light	cents per lb.	7.00
No. 1 clean brass turnings	cents per lb.	8.50
No. 1 comp turnings	cents per lb.	12.50
Lead, tea	cents per lb.	5.00
Lead, heavy	cents per lb.	7.00
Zinc, scrap	cents per lb.	5.00

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by 1 in. and larger, and plates 1/2 in. and heavier, from jobbers' warehouses in the cities named:

	New York	Cleveland	Chicago
	Current	One Year Ago	One Year Ago
Structural shapes	\$4.58	\$3.97	\$3.47
Soft steel bars	4.73	4.12	3.37
Soft steel bar shapes	4.73	4.12	3.37
Soft steel bands	6.43	5.32	4.07
Plates, 1/2 to 1 in. thick	4.78	4.17	3.67

	Carlota	Less Carlota
Potassium bitartrate (cream of Tartar).....lb.	\$0.52 - \$0.56	\$0.57 - \$0.58
Potassium bromide, granular.....lb.
Potassium carbonate, U. S. P.....lb.	50 - 55	56 - 60
Potassium carbonate, crude.....lb.	20 - 25	26 - 28
Potassium chlorate, crystals.....lb.	17 - 17 1/2	18 - 20
Potassium hydroxide (caustic potash).....lb.	27 - 28	29 - 33
Potassium iodide.....lb.	3.35 - 3.60
Potassium nitrate.....lb.	17 - 17 1/2	19 - 21
Potassium permanganate.....lb.	75 - 80	85 - 95
Potassium prussiate, red.....lb.	85 - 95	1.00 - 1.05
Potassium prussiate, yellow.....lb.	32 - 36	35 - 40
Potassium sulphate (powdered).....ton	\$240.00 - 255.00
Rochelle salts (see sodium potas. tartrate).....
Sal ammoniac (see ammonium chloride).....
Salt soda (see sodium carbonate).....
Salt cake.....ton	48.00 - 50.00
Silver cyanide (nominal).....oz.	1.25 - 1.60	62 - 62
Silver nitrate (nominal).....oz.
Soda ash, light.....100 lb.	3.20 - 3.50
Soda ash, dense.....100 lb.	3.55 - 3.65
Sodium acetate.....lb.	10 - 15	20 - 25
Sodium bicarbonate.....100 lb.	2.50 - 2.25	3.00 - 3.50
Sodium bichromate.....lb.	22 - 24	26 - 27
Sodium bisulphate (nitric cake).....ton	7.00 - 8.00	9.00 - 11.00
Sodium bisulphite (powdered, U.S.P.).....lb.	0.81 - 1.0	10 - 11
Sodium borate (borax).....lb.	0.9 - 1.0	11 - 12
Sodium carbonate (soda ash).....100 lb.	2.00 - 2.10	2.15 - 2.25
Sodium chlorate.....lb.	11 - 12	12 - 14
Sodium cyanide, 98-99 per cent.....lb.	25 - 30	32 - 35
Sodium fluoride.....lb.	18 - 19	19 - 20
Sodium hydroxide (caustic soda).....100 lb.	5.60 - 5.70	5.75 - 6.00
Sodium hyposulphite.....lb.	0.3 - 0.4
Sodium molybdate.....lb.	2.50 - 3.00	3.25 - 4.00
Sodium nitrate.....100 lb.	3.00 - 3.25	3.75 - 4.00
Sodium nitrite.....lb.	16 - 18	19 - 20
Sodium peroxide, powdered.....lb.	32 - 35	35 - 40
Sodium phosphate, dibasic.....lb.	0.31 - 0.41	0.41 - 0.5
Sodium potassium tartrate (Rochelle salts).....lb.	39 - 40
Sodium prussiate, yellow.....lb.	23 - 27	31 - 32
Sodium silicate, solution (40 deg).....lb.	0.11 - 0.11	0.2 - 0.21
Sodium silicate, solution (60 deg).....lb.	0.24 - 0.3	0.4 - 0.5
Sodium sulphate, crystals (Glauber's salt) cwt.	1.60 - 1.70	1.75 - 2.50
Sodium sulphide, crystals.....lb.	0.4 - 0.44	0.41 - 0.5
Sodium nitrate, powdered.....lb.	15 - 18	19 - 20
Sulphur chloride red.....lb.	0.8 - 0.9	10 - 10
Sulphur, crude.....ton	16.00 - 20.00
Sulphur dioxide, liquid, cylinders.....lb.	0.9 - 1.0	10 - 12
Sulphur (sublimed), flour.....100 lb.	3.80 - 4.35
Sulphur, roll (brimstone).....100 lb.	3.40 - 3.90
Tin bichloride (stannous).....lb.	42 1/2 - 44	45 - 46
Tin oxide.....lb.	55 - 65
Zinc carbonate, precipitate.....lb.	16 - 18	19 - 20
Zinc chloride, gran.....lb.	13 - 13 1/2	13 - 17
Zinc cyanide.....lb.	45 - 49	50 - 60
Zinc dust.....lb.	12 - 13	13 - 14
Zinc oxide, U. S. P.....lb.	17 - 25
Zinc sulphate.....lb.	0.31 - 0.31	0.4 - 0.6

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....lb.	\$1.40	\$1.50
Alpha naphthol, refined.....lb.	1.60 - 1.70
Alpha naphthylamine.....lb.	50 - 52	54
Aniline oil, drums extra.....lb.	30 - 33	33
Aniline salts.....lb.	35 - 40	40
Anthracene, 80% in drums (100 lb).....lb.	90 - 1.00	1.00
Benzaldehyde (f.o).....lb.	2.00 - 2.10	2.10
Benzidine, base.....lb.	1.35 - 1.40	1.40
Benzidine, sulphate.....lb.	1.15 - 1.25	1.25
Benzoic acid, U.S.P.....lb.	85 - 90	90
Benzoate of soda, U.S.P.....lb.	80 - 90	90
Benzol, pure, water-white, in drums (100 gal).....gal	38 - 40	40
Benzol, 90% in drums (100 gal).....gal	36 - 38	38
Benzoic chloride, 95-97%, refined.....lb.	35 - 40	40
Benzoic chloride, tech.....lb.	25 - 35	35
Beta naphthol benzoate (nominal).....lb.	3.50 - 4.00	4.00
Beta naphthol, sublimed (nominal).....lb.	85
Beta naphthol, tech (nominal).....lb.	80 - 85	85
Beta naphthylamine, sublimed.....lb.	2.25 - 2.40	2.40
Cresol, U. S. P., in drums (100 lb).....lb.	18 - 19	19
Ortho-cresol, in drums (100 lb).....lb.	21 - 22	22
Cresylic acid, 97-99%, straw color, in drums.....gal	1.15 - 1.20	1.20
Cresylic acid, 95-97%, dark, in drums.....gal	1.05 - 1.10	1.10
Cresylic acid, 50% first quality, drums.....gal	65 - 75	75
Dichlorobenzol.....lb.	0.8 - 1.0	1.0
Diethylamine.....lb.	1.50 - 1.60	1.60
Dinitrobenzol.....lb.	80 - 85	85
Dinitrochlorbenzol.....lb.	32 - 35	35
Dinitrophenol.....lb.	45 - 55	55
Dinitrophenol.....lb.	40 - 45	45
Dinitrotoluol.....lb.	40 - 45	45
Dip oil, 25% tar acids, car lots, in drums.....gal	38 - 40	40
Diphenylamine (nominal).....lb.	80 - 85	85
Fluoride (nominal).....lb.	2.00 - 2.25	2.25
Monophenyl-nediamine.....lb.	1.25 - 1.30	1.30
Monochlorobenzol.....lb.	18 - 20	20
Monochlorobenzol.....lb.	2.00 - 2.40	2.40
Naphthalene crushed, in bbls. (250 lb.).....lb.	19
Naphthalene, flake.....lb.	19
Naphthalene, balls.....lb.	75 - 85	85
Naphthalonic acid, crude.....lb.	14 - 19	19
Nitrobenzol.....lb.	40 - 50	50
Nitro-naphthalene.....lb.	18 - 25	25
Nitro-toluol.....lb.	3.25 - 4.25	4.25
Ortho-amidophenol.....lb.	15 - 20	20
Ortho-dichlor-benzol.....lb.	80 - 85	85
Ortho-nitro-phenol.....lb.	25 - 30	30
Ortho-toluidine.....lb.	30 - 35	35
Para-amidophenol, base.....lb.	2.50 - 3.00	3.00
Para-amidophenol, HCl.....lb.	2.50 - 3.00	3.00
Para-dichlor-benzol.....lb.	0.8 - 1.2	1.2
Paranitraniline.....lb.	1.10 - 1.15	1.15

Para-nitro-toluol.....lb.	1.35 - 1.50	1.50
Paraphenylenediamine.....lb.	2.50 - 2.65	2.65
Paratoluidine.....lb.	2.00 - 2.25	2.25
Phthalic anhydride.....lb.	60 - 70	70
Phenol, U. S. P., drums (dest.), (240 lb.).....lb.	12 - 20	20
Pyridin.....gal.	2.00 - 3.50	3.50
Resorcin, technical.....lb.	4.25 - 4.50	4.50
Resorcin, pure.....lb.	6.25 - 6.75	6.75
Salicylic acid, tech., in bbls. (110 lb.).....lb.	50 - 52	52
Salicylic acid, U. S. P.....lb.	50 - 60	60
Salol.....lb.	90 - 1.00	1.00
Solvent naphtha, water-white, in drums, 100 gal.....gal.	33 1/2 - 35 1/2	35 1/2
Solvent naphtha, crude, heavy, in drums, 100 gal.....gal.	23 - 26	26
Sulphanilic acid, crude.....lb.	32 - 35	35
Toluidine.....lb.	1.70 - 2.50	2.50
Toluidine, mixed.....lb.	45 - 55	55
Toluol, in tank cars.....gal.	35 - 40	40
Toluol, in drums.....gal.	38 1/2 - 40 1/2	40 1/2
Xylidine, drums, 100 gal.....lb.	50 - 65	65
Xylol, pure, in drums.....gal.	47 1/2 - 50 1/2	50 1/2
Xylol, pure, in tank cars.....gal.	45 - 48	48
Xylol, commercial, in drums, 100 gal.....gal.	32 1/2 - 35 1/2	35 1/2
Xylol, commercial, in tank cars.....gal.	30 - 35	35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....lb.	\$0.36 - \$0.39	\$0.39
Beeswax, refined, light.....lb.	37 - 38	38
Beeswax, white pure.....lb.	63 - 68	68
Carnauba, No. 1 (nominal).....lb.	90 - 95	95
Carnauba, No. 2, regular (nominal).....lb.	85 - 86	86
Carnauba, No. 3, North Country.....lb.	35 - 36	36
Japan.....lb.	17 - 18	18
Montan, crude.....lb.	25 - 26	26
Paraffine waxes, crude match wax (white) 105-110 m.p.....lb.	0.9 - 0.91	0.91
Paraffine waxes, crude, scale 124-126 m.p.....lb.	0.91 - 1.0	1.0
Paraffine waxes, refined, 118-120 m.p.....lb.	11 - 11 1/2	11 1/2
Paraffine waxes, refined, 125 m.p.....lb.	12 1/2 - 13	13
Paraffine waxes, refined, 128-130 m.p.....lb.	13 - 15	15
Paraffine waxes, refined, 133-135 m.p.....lb.	16 - 17	17
Paraffine waxes, refined, 135-137 m.p.....lb.	17 1/2 - 18 1/2	18 1/2
Stearic acid, single pressed.....lb.	20 - 21	21
Stearic acid, double pressed.....lb.	22 - 23	23
Stearic acid, triple pressed.....lb.	24 - 25	25

NOTE—Paraffine waxes very scarce.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oil in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....gal.	\$2.15
Pine oil, pure, dist. dist.....gal.	1.80
Pine tar oil, ref., sp. gr. 1.025-1.035.....gal.	48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....gal.	35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....gal.	85
Pine tar, ref., thin, sp. gr. 1.080-1.060.....gal.	36
Turpentine, crude, sp. gr. 0.900-0.970.....gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....gal.	35
Pine wood creosote, ref.....gal.	52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Resin B-D, bbl.....280 lb.	\$14.60
Resin E-L, bbl.....280 lb.	14.50
Resin K-N.....280 lb.	14.50
Resin W-G-W-W.....280 lb.	14.50
Wood rosin, bbl.....280 lb.	15.00
Spirits of turpentine.....gal.	1.49
Wood turpentine, steam dist.....gal
Wood turpentine, dist. dist.....gal
Pine tar pitch, bbl.....200 lb.	8.50
Tar, kiln burned, bbl. (500 lb).....bbl.	14.50 - 15.00	15.00
Retort tar, bbl.....500 lb.	15.00 - 15.50	15.50
Rosin oil, first run.....gal.	72
Rosin oil, second run.....gal.	75
Rosin oil, third run.....gal.	92

Solvents

73-76 deg., steel bbls. (85 lb.).....gal.	\$0.40
70-72 deg., steel bbls. (85 lb.).....gal.	38
68-70 deg., steel bbls. (85 lb.).....gal.	37
V. M and P. naphtha, steel bbls. (85 lb.).....gal.	29

Crude Rubber

Para—L'priver fine.....lb.	\$0.29 - \$0.31
L'priver coarse.....lb.	19 - 20	20
L'priver caucho ball.....lb.	20 - 22	22
Plantation First latex crepe.....lb.	30 - 35	35
Ribbed smoked sheets.....lb.	28 - 30	30
Brown crepe, thin, clean.....lb.	26 - 28	28
Amber crepe No. 1.....lb.	28 - 30	30

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.....lb.	\$0.16 1/2 - \$0.18
Castor oil, AA, in bbls.....lb.	19 - 20	20
China wood oil, in bbls. (f.o.b. Pac. coast).....lb.	14 1/2 - 16	16
Cocconut oil, Ceylon grade, in bbls.....lb.	15 - 16	16
Cocconut oil, Cochon grade, in bbls (nominal).....lb.	17 - 17 1/2	17 1/2
Cora oil, crude, in bbls.....lb.	12 - 13	13
Cottonseed oil, crude (f.o.b. mill).....lb.	0.00 - 0.11	0.11
Cottonseed oil, summer yellow.....lb.	12 1/2 - 13 1/2	13 1/2
Cottonseed oil, winter yellow.....lb.	17 1/2 - 18 1/2	18 1/2
Linseed oil, raw, car lots (domestic).....gal.	1.25 - 1.28	1.28
Linseed oil, raw, tank cars (domestic).....gal.	1.22 - 1.25	1.25
Linseed oil, boiled, car lots (domestic).....gal.	1.33 - 1.35	1.35

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

PHOENIX—The Arizona Gypsum Co., 213 West Washington St., will build a 2-story gypsum plaster plant. Estimated cost, \$40,000. Work will be done by day labor.

Colorado

DENVER—The Concrete Steel Co., 42 W. 17th Ave., New York City, will build a 1-story, 200x200-ft. steel fabricating shop here. Estimated cost, \$200,000. Work will be done by day labor.

Connecticut

SEYMOUR—The Seymour Mfg. Co., 87 Franklin St., has awarded the contract for the construction of a 1-story foundry addition to the H. Wales Lines Co., 134 State St., Meriden. Estimated cost, \$25,000.

STAMFORD—Richards & Co., Inc., Ludlow St., has awarded the contract for the construction of a 1- and 3-story factory on Canal and Ludlow Sts. to the J. W. Ferguson Co., 602 West 110th St., New York City. Estimated cost, \$75,000.

Florida

KEY WEST—The Bureau of Yards & Docks, Navy Dept., Washington, D. C., plans to build a distillation plant here.

Illinois

CENTRALIA—The Township High School Bd. has awarded the contract for the construction of a 2-story, 130x130-ft. high school to the G. E. Tillman Constr. Co. A chemical laboratory will be installed in same. Estimated cost, \$100,000.

EAST ST. LOUIS—The Eagle-Picher Lead Co., Ry. Exch. Bldg., St. Louis, Mo., has awarded the contract for the construction of a factory to the Wimmer Contg. Co., Victoria Bldg., St. Louis, Mo. A chemical laboratory will be installed in same. Estimated cost, \$600,000.

EAST ST. LOUIS—The Monsanto Chemical Wks., 1800 South 2d St., St. Louis, Mo., has awarded the contract for the construction of 7 factory buildings to the Wimmer Contg. Co., Victoria Bldg., St. Louis, Mo. Estimated cost, \$400,000.

GRANITE CITY—The Bd. Educ. had plans prepared for the construction of a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, \$225,000. W. B. Ittner, Bd. Educ. Bldg., St. Louis, Mo., archt. Noted Aug. 4.

HERRIN—The Bd. of Educ. has awarded the contract for the construction of a 2-story, 130x142-ft. high school to P. Cordani. A chemical laboratory will be installed in same. Estimated cost, \$123,600. J. W. Kennedy, East St. Louis, archt. and engr.

MCLAN—The Bd. Educ. has awarded the contract for the construction of a 46x102-ft. high school to J. C. Newlin, Bloomington, Ill. A chemical laboratory will be installed in same. Estimated cost, \$100,000. J. Howard Baker, secy.

Indiana

INDIANAPOLIS—The Milan Tire & Rubber Co., c/o Myron Wilson, Hotel Cleveland, Cleveland, Ohio, plans to build a 3-story rubber factory. Estimated cost, \$350,000. Carter-Richard-Griffith Co., Illuminating Bldg., Cleveland, Ohio, archts. and engrs.

MICHIGAN CITY—The Amer. Iron & Steel Corp. plans to build a 1-story steel plant consisting of a 250-ton blast furnace, 6 open-hearth furnaces and a 12-mill sheet steel plant, etc. Estimated cost, \$50,000,000. L. L. Sick, Engineers' Bldg., Cleveland, Ohio, dir.

PRINCETON—City Council will soon award the contract for the construction of a sewage disposal plant. Estimated cost, \$41,850.

Iowa

WATERLOO—The Bd. Educ. has awarded the contract for the construction of a school to H. A. Maine Co. A chemical laboratory will be installed in same. Estimated cost, \$800,000.

Kansas

TOPEKA—The city is having plans prepared for the construction of a water purification plant. Estimated cost, \$400,000.

Kentucky

LOUISVILLE—The Ewald Iron Co., 224 North Clay St., plans to build an addition to foundry. Estimated cost, \$3,000,000. H. B. Hickman, pres.

Maine

BANGOR—The Keyes Fibre Co., Waterville, plans to build a 40-ton capacity, electrically operated mill.

Maryland

BALTIMORE—The Baltimore Brick Co., 708-710 Maryland Trust Bldg., will soon award the contract for the construction of a 1-story brick drier and brick kiln.

BALTIMORE—The Bd. of Awards, c/o City Register, will soon award the contract for the construction of a sludge digestion tank, pipe lines, etc., at the sewage disposal works on the shore of the Back River here. A. E. Christhill, engr. Noted Aug. 25.

BALTIMORE—The Johns Hopkins University is having plans prepared for the construction of a 2-story chemical laboratory. Estimated cost, \$150,000. Carrere & Hastings, 52 Vanderbilt Ave., New York City, engrs.

BALTIMORE—The Prest-O-Lite Co., Inc., 30 East 42d St., New York City, has awarded the contract for the construction of a 1-story, 25x50-ft. acetylene plant in connection with the 3 proposed acetylene buildings here to the West Constr. Co., Foster and 13th Aves. Estimated cost, \$75,000. Noted June 23.

Massachusetts

BROCKTON—The city has awarded the contract for the construction of filter beds to the Geo. Howard & Sons Co., 153 Main St. Estimated cost, \$155,207. H. S. Crocker, city engr. Noted Sept. 1.

FALMOUTH—The Standard Oil Co. of New York, 50 Congress St., Boston, has awarded the contract for the construction of a 1- and 2-story oil plant to Hardy & Streeter, 95 Milk St., Boston. Estimated cost, \$30,000.

HARVICH—The Standard Oil Co. of New York, 50 Congress St., Boston, has awarded the contract for the construction of a 1-story oil plant to Hardy & Streeter, 95 Milk St., Boston. Estimated cost, \$30,000.

HYANNIS—The Standard Oil Co. of New York, 50 Congress St., Boston, has awarded the contract for the construction of a 1-story oil plant to Hardy & Streeter, 95 Milk St., Boston. Estimated cost, \$35,000.

NEW BEDFORD—The Sassaquin Sanatorium plans to build a 1-story, 38x70-ft. laboratory here.

SPRINGFIELD—The Forging Service Corp., 318 Main St., will soon award the contract for the construction of a 1-story, 45x125-ft. forge shop on Switzer Ave. Estimated cost, \$20,000.

WAKEFIELD—Hoywood Bros. and the Wakefield Co., 206 Central St., Gardner, has awarded the contract for the construction of a 1-story factory addition to the Leighton Mitchell Co., 99 Chauncey St., Boston. Estimated cost, \$75,000.

WARE—The Ware Coated Paper Co., South St., has awarded the contract for the construction of a 1-story, 70x100 ft. paper factory on Cummings St. to P. H. Provencal, 127 North St. Estimated cost, \$40,000.

Michigan

HOUGHTON—The Michigan College of Mines, College Ave., has awarded the contract for the construction of a 2-story chemical building to Herman Gundlach, Leopold Bldg. Estimated cost, \$125,000. Noted May 19.

MONROE—The Monroe Auto Equipment Co., East 1st St., plans to build a 1-story, 90x200-ft. foundry. Reed M. Dunbar, archt.

SAGINAW—The American Safety Navigation Co., c/o Managing Secy. Bd. of Commerce, is having plans prepared for the construction of a 1-story factory for the manufacture of aluminum life rafts, etc., and a 6-story office building. This is first unit of a \$10,000,000 plant.

Missouri

GRANT CITY—The City Clerk will receive bids until Sept. 21 for the construction of a disposal plant including a Imhoff tank, filtering material, etc. Black & Veatch, Mutual Bldg., Kansas City, engrs.

ST. LOUIS—The Bridge & Beach Mfg. Co., 503 South 1st St., has awarded the contract for the construction of 17 buildings on Union and Brown Aves. to the Fruin Colonn Contg. Co., Merchants' Laclede Bldg. A small chemical laboratory will be installed in same. Estimated cost, \$800,000.

ST. LOUIS—Lindenwood College, 3715 McCouland St., has awarded the contract for the construction of a 4-story, 104x168 ft. college building to the Sutherland Constr. Co., Syndicate Trust Bldg. A chemical laboratory will be installed in same. Estimated cost, \$350,000.

ST. LOUIS—St. John's Hospital, Euclid St. and Parkview Pl., has awarded the contract for the construction of a hospital addition on Euclid St. to the Rodman Bldg. & Constr. Co. A chemical laboratory will be installed in same. Estimated cost, \$175,000.

ST. LOUIS—The Magnus Metal Co., 4153 Clayton Ave., has awarded the contract for the construction of a 1-story foundry on present site to the Wimmer Contg. Co., Victoria Bldg. Estimated cost, \$60,000.

New Jersey

BRIDGETON—The Illinois Glass Co. plans to build a glass factory. Estimated cost, \$3,500,000. Alex. Godfrey, genl. mgr.

NEW BRUNSWICK—The Western Sulphur Co. plans to construct a fertilizer plant. Estimated cost, \$150,000. J. G. Lipman, State Agricultural College, pres.

TRENTON—The Luzerne Rubber Co., Muirhead Ave., has awarded the contract for the construction of a 1-story, 80x80-ft. rubber plant on Muirhead Ave. to the Karno Smith Co., Broad St. Estimated cost, \$15,000.

TRENTON—The Mutual Pottery Co., Clinton Ave., has awarded the contract for the construction of a pottery plant to Stone & Webster, 120 B'way, New York City. Estimated cost \$500,000. Noted May 4.

TRENTON—The Puritan Rubber Mfg. Co., Perrine Ave., plans to construct a 1-story rubber plant. Estimated cost, \$7,000.

New York

BROOKLYN—C. A. Benoit, Jerome Ave., will soon award the contract for the construction of a 3-story dye factory on Ave. I. Estimated cost, \$200,000.

BUFFALO—Pratt & Lambert, Inc., 79 Tonawanda St., has awarded the contract for the construction of a 4-story, 55x100-ft. factory for the manufacture of varnish to the John W. Cowper Co., Fidelity Bldg. Estimated cost, \$75,000.

North Dakota

MARMARTH—The Bd. Educ. will soon award the contract for the construction of a 2-story, 61x91-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. Noted Aug. 25.

Ohio

BENTLEY (Columbus P. O.)—The city received bid for the construction of an extension to the sewage disposal plant from the Sheets Constr. Co., 1468 Pennsylvania Ave., \$5,600.

CHAGRIN FALLS—Ernest McGeorge, engr., 1900 Euclid Ave., Cleveland, will soon award the contract for the construction of a 2-story, 60x120-ft. paper mill addition for the Adams Bag Co., Chagrin Falls. Estimated cost, \$100,000. Noted July 7.

CLEVELAND—The Atlantic Fdry. Co., East 75th St. and Morgan Ave., has awarded the contract for the construction of a 1-story, 21x100-ft. foundry addition to the Bolton Pratt Constr. Co., Columbia Bldg. Estimated cost, \$10,000.

CLEVELAND—The Bd. Educ. is having plans prepared for the construction of a 3-story high school at Woodland Hills. A chemical laboratory will be installed in same. Estimated cost, \$2,000,000. W. R. McCormick, East 6th St. and Rockwell Ave., archt.

CLEVELAND—The Cleveland Camshaft Co., 6520 Carnegie Ave., has awarded the contract for the construction of a 1-story, 39x11-ft. heat treating plant to the Stevens Iron Works Co., 4300 Perkins Ave. Estimated cost, \$15,000.

CLEVELAND—The Concrete Steel Co., 12 B'way, New York City, will build a 1-story, 200x200-ft. steel fabricating shop here. Estimated cost, \$20,000. Work will be done by day labor.

CLEVELAND—The Concrete Steel Co., Guardian Bldg., plans to build a 1-story, 70x200 ft. factory on Bora Rd. Estimated cost, \$75,000. W. Bright, mgr.

CLEVELAND—The A. S. Gilman Co., 623 St. Clair Ave., has awarded the contract for the construction of a 2-story, 90x119-ft. factory addition to the Myers-Kuhn Constr. Co., 210 Metropolitan Bldg. Estimated cost, \$50,000.

CLEVELAND—The Natl. Carbon Co., West 117th St. and Madison Ave., plans to build a 1-story factory addition. Estimated cost, \$150,000. P. R. Magee, engr.

COLUMBUS—The Capital City Products Co., West First Ave., is having plans prepared for the construction of a 2-story, 100x165-ft. factory addition. Estimated cost, \$100,000. Bossett & Trisselt, Central Natl. Bank Bldg., archts.

COLUMBIA—The Cleveland Trinidad Paving Co., Grand Theatre Bldg., is having plans prepared for the construction of a 1-story, 100x175 ft. asphalt plant on Dublin Rd. Estimated cost, \$60,000.

HOLMESVILLE—The High School Bd. plans to build a 2-story, 63x76-ft. high school. A chemical laboratory will be installed in same. T. E. Crawford, clk.

SPRINGFIELD—The Bd. Educ. will receive bids until Sept. 21 for the construction of a 2-story, 110x128 ft. high school on Malden Lane. A chemical laboratory will be installed in same. Estimated cost, \$225,000. O. D. Hind, 8 East Broad St., Columbus, archt.

Oklahoma

LAWTON—The city has received preliminary report for the construction of a sewage disposal plant and pumping station. Estimated cost, \$200,000. V. V. Long & Co., 1300 Concord Bldg., Oklahoma City, consult. engr.

PURCELL—The city plans an election to vote on \$382,000 bonds to construct a filtration plant, etc. Johnson and Benham, Firestone Bldg., Kansas City, Mo., engr.

STIGLER—The city has received preliminary report for the construction of waterworks extensions including water purification plant, etc. Estimated cost, \$35,000. V. V. Long & Co., 1300 Concord Bldg., Oklahoma City, consult. engr.

Pennsylvania

ERIE—The Bd. Educ. will soon award the contract for the construction of a high school. A chemical laboratory will be installed in same. W. B. Itner, Bd. Educ. Bldg., archt.

KITTANNING—The Kittanning Iron & Steel Co. is having plans prepared for the construction of a 1-story steel plant addition. Estimated cost, \$100,000. Arthur G. McKee Co., 2122 Euclid Ave., Cleveland, Ohio, engr.

PHILADELPHIA—Rinald Bros., 1142 Hancock St., will soon award the contract for the construction of a 2-story, 16x55-ft. varnish building on Grove and Wharton Sts. Penchert & Wunder, 1415 Locust St., archts. and engr.

Tennessee

CHATTANOOGA—The Cole Eng. Co. of Philadelphia, Pa., has purchased a site here and plans to build a factory for the manufacture of lubricating steel on same.

CHATTANOOGA—The DuBois Rubber & Tire Co. plans to construct a factory for the manufacture of rubber products.

Texas

DALLAS—The city is having plans prepared for the construction of a water purification plant for the White Rock Reservoir. Estimated cost, \$350,000. G. D. Fairtrace, City Hall, engr.

DUBLIN—The Keystone Refining Co. has awarded the contract for furnishing equipment for the proposed refinery here. Estimated cost, \$400,000.

Vermont

BELLOWS FALLS—The Liberty Paper Co., Inc., has awarded the contract for the construction of a 3-story factory to the Guarantee Constr. Co., 140 Cedar St., New York City. Estimated cost, \$130,000.

HARTFORD—The International Paper Co., 15 Milk St., Boston, Mass., has awarded the contract for the construction of a 2-story paper factory to the H. P. Cummings Constr. Co., 14 Prospect St., Ware, Mass. Estimated cost, \$50,000.

Virginia

HAMPTON ROADS—The Bureau Yards & Docks, Navy Dept., Washington, D. C., plans to build a distillation plant here.

MONTPELIER—The School Bd., c/o J. W. Hall, Supt. of Public Schools, Ashland, is in the market for chemical laboratory equipment.

Washington

YAKIMA—The Puritan Rubber Co., 16-17 Wilson Bldg., plans to build a 60x250-ft. factory for the manufacture of tires, tubes, etc. Estimated cost, \$250,000. W. L. Lanning, Wilson Bldg., engr.

Wisconsin

BURLINGTON—The city plans to build a sewerage system including a septic tank. Estimated cost, \$75,000. C. H. Tubbs, engr.

BUTTE RIVER—Edward Ross, Phillips, will soon award the contract for the construction of a 1-story, 60x250-ft. veneer plant on Main St. Estimated cost, \$100,000.

FOND DU LAC—The Bd. Educ. will soon award the contract for the construction of a 3-story, 66x260-ft. high and vocational school. A chemical laboratory will be installed in same. Estimated cost, \$350,000. Childs & Smith, 61 East Van Buren St., Chicago, archts. Noted July 16.

MILWAUKEE—The Sewerage Comm. plans to build a fine screen building including equipment. Estimated cost, \$325,000.

SAUKVILLE—George Sulman & Sons Co., 337 1st St., Milwaukee, has awarded the contract for the construction of a 2-story, 57x119-ft. leather factory on Main St. to John Schramka, Port Washington. Estimated cost, from \$15,000 to \$50,000.

SHERBOGAN—Juhl & Smith, archts., Indig Bldg., will soon award the contract for the construction of a 2-story, 70x100-ft. foundry for the Columbia Rubber Mills, 178 16th St., Milwaukee. Estimated cost, from \$50,000 to \$75,000. Noted Aug. 11.

Wyoming

DODGE—The city voted \$75,000 bonds for the construction of a water supply system and filtration plant. Geo. T. Prince, c/o Prince, Nixon Co., Omaha, Neb., consult. engr.

Canada

WELLAND—The Joseph Stokes Rubber Co. has awarded the contract for the construction of a 1-story rubber mill and power plant on Johns and Bernard Sts. to the Karvo Smith Co., Broad St. Bank Bldg., Trenton. Estimated cost, \$100,000.

Manitoba

WINNIPEG—The Dominion Oxygen Co. will soon receive bids for the construction of a plant for the manufacture of oxygen for welding purposes. Estimated cost, \$100,000.

Nova Scotia

WINDSOR—T. B. Akins, Windsor, and Wright & Jodrey, Wolfville, are interested in a company which is having plans prepared for the construction of a small pulp mill, etc. Estimated cost, \$250,000.

Ontario

SUDBURY—The International Nickel Co. will soon receive bids for the construction of a rolling mill. Estimated cost, \$3,000,000.

NEWMARKET—The city has awarded the contract for the construction of an outfall sewer and activated sludge plant to Currant & Briggs, Orillia. Estimated cost, \$34,000. E. A. James Co., Ltd., 36 Toronto St., Toronto, engr. Noted Jan. 7.

FORT ARTHUR—The Provincial Paper Mills, Ltd., of Toronto, plans to construct a paper mill here.

Prince Edward Island

CHARLOTTETOWN—Bruce Stewart & Co. will receive bids for the construction of a 60x120-ft. plant for the manufacture of gasoline engines.

Quebec

ALLARD FALLS—The Manouay Pulp & Paper Co. will soon receive bids for the construction of a plant here. Frank L. Moore, Newton Falls Paper Co., Watertown, N. Y., is interested.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1920 convention and exhibit at Columbus, Ohio, the week of Oct. 1.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1920 annual meeting will be held in the Engineering Societies' Building, from Dec. 7 to 10 inclusive.

AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS will hold its 14th annual convention at the Hotel Pennsylvania, New York City, Sept. 20 to 21, 1920.

THE CHEMICAL WARFARE POST of the American Legion will hold its next meeting Sept. 22, at 8 p.m., in the conference room of the Grand Central Palace, New York City.

ELECTRIC FURNACE ASSOCIATION will hold a meeting Oct. 6, at Columbus, Ohio, the subject of which will be "Refractories."

ENGINEERING COUNCIL will hold its next meeting in Chicago Thursday, Oct. 21, 1920.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SIXTH) will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE RUBBER SECTION of the National Safety Council will consider safety problems of especial interest to the rubber industry at a section conference to be held Sept. 29 to Oct. 1, in connection with the national session of the Council to be held in Chicago.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12, 1920.

The Cost of Hospitality

IF FORTUNE favored you with attendance at the Chicago meeting of the American Chemical Society week before last you probably were impressed with the generous hospitality and the cordial goodfellowship that marked that happy occasion. From Northwestern University on the north to Chicago University on the south and among the industrial plants in the environs of the city there was open house for visiting chemists. Careful forethought was given to every detail and a suitable setting was provided for every function. The program proceeded with clocklike precision. At no recent convention within our recollection, confined to a single city, was there a better opportunity for social intercourse as well as exchange of technical information. The entertainment was in good taste, and personal preference was anticipated in great variety. If there was a hitch anywhere it was not evident to the visitor.

We wonder, however, whether those who enjoyed all that was offered had a lively sense of what was involved in preparation for the event: the detailed work of committees, the co-operation of varied interests, the conferences, the devotion of time and money. We may take for granted the personal service and sacrifice involved in preparing for a great meeting of scientists, but the financial burden is likely to be overlooked and not appreciated. Certainly \$20,000 would not cover the cost of entertainment and hospitality afforded at Chicago. Somebody has to pay for special trains, dinners, orchestras, operettas, organ recitals and all the trimmings that go to make up a successful convention. Undoubtedly the most distasteful job was that of the finance committee, which had to solicit funds from companies which, in many cases, had only a remote interest in the convention and whose ability to contribute constituted the best reason for approaching them.

In the light of these considerations the Council of the Society is to be commended for resolving that at future meetings the attendants shall bear a share of the cost of their entertainment. The mechanism whereby this is to be accomplished is not decided upon, but the principle is fair. We can go further and question whether, after all, it is necessary to provide entertainment on such a scale that it becomes a burden. As the Society foregathers at one city after another a commendable spirit of rivalry not only leads each successive local organization into emulation of the plans of its predecessor but creates a desire to "go one better," thus adding another limitation to the centers that are able and willing to act as occasional hosts to the parent organization. From every point of

view it seems as though less stress should be laid on the formal entertainment of guests and more on the facilities and natural attractions of possible convention centers. Delightful as the social features are, they may add too much to the cost of hospitality.

The First Meeting of American Engineering Council

ANNOUNCEMENT is made elsewhere in this issue of the first meeting of American Engineering Council of the Federated American Engineering Societies. It will be an important occasion in the history of American engineering, and the national capital will be a fit setting for it.

We have followed with more than ordinary interest the development of this organization, which is an earnest attempt to provide a vehicle for expression of engineering thought and for impressing that kind of thinking on public affairs, municipal, state and national. Of the value of engineering opinion on public affairs we are thoroughly convinced, and we are committed to the necessity of making the composite engineering thought of this country articulate. The war brought the engineer and kindred technical men out of their professional seclusion and aroused in them a modest sense of importance in the general scheme of things. The consciousness thus created must now be fostered for at least two good reasons: recognition of engineers as a powerful and intelligent group of citizens, and the benefit which will result to the country from their participation in the conduct of its affairs. The effect will be cumulative. Intelligent participation will lead to public recognition of the profession; and that public recognition, in turn, will foster the spirit of professional solidarity and consciousness that will encourage further public service.

The principal need at this time is an active instrument for accomplishing these aims and purposes. The work of the Organizing Conference in Washington last June resulted in the creation of the Federated American Engineering Societies. Its constitution calls for representation of constituent societies in American Engineering Council, which, in turn, shall function through an elected Executive Board. It is for the formal organization of the Council and its Executive Board that the forthcoming Washington meeting is called.

The Federation is now an established, going concern. Since it was organized last June, five societies, national and local, have joined, making it the largest engineering society in the world. Delegates from the member societies—American Society of Mechanical Engineers, American Institute of Electrical Engineers, Technical Club of Dallas, Cleveland Engineering Society and Detroit Engineering Society—will comprise and organize American Engineering Council. Between now and November

18, when the meeting will be held, as many as possible of the fifty-seven societies which participated in the Organizing Conference last June, should take action on membership in the Federation so that they can send delegates to the opening session. The success of this movement is not going to reside in the participation of the large national societies alone, but in the large number of local, state and regional organizations that can represent engineers from every part of the country. On these bodies we urge immediate and favorable action. Two months remain in which to inform their members of the movement, stimulate interest and hold a referendum.

We are unwilling to believe that, if the aims and purposes of the organization are placed intelligently before engineers generally, they will fail to give it cordial support. And we are equally certain that in joining the movement every society will be rendering an incomparable service to engineering. From now to November 18 should be a campaign period for membership in the Federated American Engineering Societies.

Keeping the Two Schools of Chemists Apart

AT THE semi-annual luncheon of the Harvard Alumni Chemists Association during the A.C.S. meeting at Chicago, Dr. WILLIAM J. HALE voiced the opinion that the chemical department of the college and graduate school should confine itself to pure science and not allow industrial interest to divert the attention of the students. Granting the need of sound scientific training, we might report Dr. HALE'S remarks without any comment, but the situation really calls for a little illumination.

Back in the '50s when Professors COOK and HORSFORD taught at Harvard College and Lawrence Scientific School, respectively, the students of the one were not allowed to attend the lectures of the other. That they should have been denied the privilege was a great misfortune, especially for Professor HORSFORD'S students, because the latter cared little for teaching and devoted almost his entire attention to phosphoric acid technology. Ever since, it has been the experience of the university that the best teachers usually have been those who have not had their attention divided between industry and science, who did not seek the financial reward of the former but were content with the honor attached to the latter. This has had important exceptions, the faculty of the graduate school of engineering being the most notable. Recently it has been decided to place industrial chemistry in the Harvard Engineering School and professional industrial chemists will be invited to join the faculty on a part-time basis.

Professor PAUL G. BAXTER has been appointed director. He is a great teacher, being a leader in the instruction of quantitative analysis. The future success of the industrial course depends on two things: Teaching engineers must be enlisted of the caliber now serving in the mechanical, civil, sanitary, metallurgical and electrical departments, able men, such as MARKS, DAVIS, SWAIN, HUGHES, WHIPPLE, SAUVEUR and KENNELLY. Next this new department must be tied up with and get co-operation from the chemical, physics, mathematics, economics and English departments. All policies such as Dr. HALE advocates should be limited in execution, the college laboratories never being allowed to become the hired workshops of industry or the playground of would-be chemical philosophers. Chemical engineers

must be well founded in pure science and their attendance should be welcomed in the chemical courses. It does not seem right that the engineering school should be forced to establish a department of its own, though it did so in mathematics, but by reason of the large numbers requiring specialized mathematics.

Steering An Even Course

THE War Trade Board has announced that it "does not feel it advisable to take active steps to place upon the market foreign-made drugs which would compete with those of domestic manufacture, and therefore will not exercise its option upon impounded stocks of chemical drugs of German manufacture or upon stocks of chemical drugs manufactured during the months of January, 1920, to June, 1920, inclusive." In choosing this course the Board avoids the Scylla of encouraging competition with domestic industry.

Moreover, to reassure us that we are not to run upon Charybdis, which guards the other side of the entry to our port of established chemical industry, we also read that undue aloofness in international trade is not to be expected. The Board says: "This Government will, however, retain its right to participate in allotments from future daily production of chemical drugs which may be manufactured by Germany during the next four and one-half years, in view of the possibility that a need in this country may arise at some future time for certain chemical drugs which may at that period be unobtainable from domestic sources."

The principles which guide to these decisions are right and rightly applied here. The only question which can disturb us is whether there will be enough facts always at hand to permit intelligent decision upon each new case which will arise. The industries must see that there is no lack of such information, both with respect to industrial needs and regarding the demonstrated ability of industry to fill these demands.

What About It Next Time?

THE War Department has just announced a summary of the causes of injury resulting in admission to American Expeditionary Force hospitals during the war period. Gas was the most frequent cause of injury, having occasioned almost 90,000 hospital cases, or over one-third of the total. The chemist can well ask what will happen next time, when the practice of gas warfare will doubtless begin from the outset and continue even more vigorously than it was practiced at any stage of the recent hostilities. It seems that this situation alone should be ample demonstration of the need of continued support for the Chemical Warfare Service not only by chemists but also by the General Staff of the Army, which as yet does not seem to have "seen the light."

It is to be hoped that both offensive and defensive preparations by this arm of the service will be developed to the full. We have no desire to develop our military forces to the point where, like Germany's, it will wag the entire economic life and international relations of the country, but they were at least prepared—so prepared in materials and methods that two allied soldiers had to give their lives to kill one Hun.

The Peace Treaty And Germany's "Ability"

EXTENDED reference to the moral and political questions involved in the Treaty of Versailles is not especially called for in these columns, but discussion of the engineering, metallurgical and economic matters bearing upon fulfillment by Germany of the treaty's terms is strictly in place. As everyone knows, there is heated debate in many quarters as to Germany's "ability" to carry out the terms imposed. From most of this debate knowledge of what engineering has accomplished and recognition of how industries have grown are conspicuously lacking.

There is the question of Germany's ability to furnish certain tonnages of coal. This matter is sagely discussed on the basis of the quantity of coal Germany was producing before the war. There is no reference to the quantity of coal lying beneath Germany's soil or to the number of men that can be transferred from the prosecution of strictly private affairs in Germany to the equipment and operation of coal mines and to the provision of the necessary transportation. It is an engineering or industrial fact, however, that a country can increase its production of coal and its capacity to produce coal. There is the case of the United States, for example. Fifteen years ago, in 1905, we produced 315 million net tons of bituminous coal, which was a large output for the time, being a 12 per cent gain over the previous record, made a couple of years earlier, so that it is fairly citable as a measure of the state of affairs in the United States in 1905. If we had been signing a peace treaty in 1906 requiring us to furnish coal to the victors, the 315 million tons would have been used by the statesmen as the measure of our ability. Now, however, we have the United States Geological Survey reporting that in the week ended Aug. 21 last we produced 11,048,000 net tons of coal, and that the average operation of the mines was 60 per cent, this being in reference to mine capacities based on an eight-hour day. Working an average of 4.8 hours a day, our mines actually produced coal at the rate of 575 million tons a year, or an 83 per cent gain in fifteen years, while our capacity, if we pulled ourselves and our railroads up to the point of eight-hour operation, would be just three times our output of fifteen years ago.

That is the viewpoint of engineering and industry rather than of statesmen and those who defend or criticize them. Germany's production of coal had actually increased by 18 per cent in ten years before the war, but that was a matter of business. It was not the measure of ability to produce or to increase productive capacity. In the same period the production of iron ore by Germany and Luxemburg had increased by 69 per cent. That increase was due to the fact that the increase was desired.

As inappropriate as the disregard of engineering and industrial possibilities is the importance attached to the redistribution of the Minette iron ore deposits. It is even alleged by some that the mental attitude of the men in the respective countries will prevent the iron ore being used to advantage. Of course Europe cannot be repaired physically if mental attitudes are allowed to stand in the way, but what is physically necessary to be done must be done. The whole space circumscribed by the ore mines, coal mines and blast furnaces involved in the peace treaty is astonishingly

small from the viewpoint of what the American industry does. Thirty, fifty, seldom more than a hundred miles! We transport iron ore from the Mesaba Range a thousand miles to Pittsburgh, and bring ore from Cuba and Chile to Pennsylvania.

Time may be required for the necessary equipment to be provided and for business arrangements to be made, but the iron ore and coal are in the occupied territory, some blast furnaces are there and others can be built. The things necessary will have to be done. The Treaty of Versailles might be all right or all wrong—neither of which it is—but an American engineer would be far from holding up his helpless hands if he had to get out the necessary quantities of ore and coal asked for. Give him time to organize the task along sound engineering principles, and the job would be merely a routine matter.

Steel Treathers, Bon Voyage!

PHILADELPHIA entertained the first meeting of the amalgamated heat treating societies last week, and the occasion gave gratification to its sponsors. A few scientifically inclined men working in hardening and tool rooms realized the advantage of interchanging experiences only a few years ago, yet the movement, started in so small a way, has gathered great impetus within the past year or two, and the technical meetings, industrial exhibits and other features of this convention were quite worthy of a long-established society.

As pointed out by ALBERT E. WHITE, the president, the outstanding opportunity of the new society is to replace the rule-of-thumb methods inherited from an ancient and honorable craft by the scientific control made possible by researches into physical metallurgy. Primarily, of course, it will do its share in this big task of education by exchange of information in the local and national meetings; an intelligent and inquisitive state of mind, if it can be thus aroused, will go forward by its own volition. In addition, steel maker and steel treater can be brought closer together. This new society is not greatly interested in the metallurgical and mechanical operations in the steel mill; it primarily wants to know how to distinguish good steel from bad, and then institute the proper methods of working stock metal into highly fabricated articles of unexceptionable endurance and quality. Yet the steel maker should know the steel-treater's requirements so he can furnish the raw material; on the other hand reciprocal knowledge is necessary so that the hardener may not try to develop properties not latent in his available raw material. Shop men, from foremen to apprentices, should also utilize the new society as a meeting ground. Most of the shop men are still craftsmen, practicing an art rather than applying a science. Foremen and managers can most easily dispel prejudice and ignorance, develop enthusiasm and enlist co-operation in the solution of vexatious economic problems of production by joining the artisans and technicians man to man in the technical sessions of this society.

Truly the newly amalgamated American Society for Steel Treating has picked out a limitless and inspiring field of action—education. Its influence for good should be immeasurable. Unquestionably we voice the thoughts of all men interested in making good steel better when we say heartily, "Godspeed!"

Chicago Meeting of the American Chemical Society

An Account of the Social and Technical Features of the Sixtieth Meeting—Council Meeting—Addresses at the General and Industrial Division Meetings—Synopsis of Papers on Physical and Inorganic Chemistry, Cellulose, Sugar and Dyes

THE sixtieth general meeting of the American Chemical Society was held in Chicago, Sept. 6 to 10. Headquarters was maintained at the Congress Hotel, where several general lectures and the banquet were held. The technical sessions were held in the lecture rooms of Chicago University, while the social functions were given at Northwestern University. This scattered the meeting's activities over a rather wide area, but it was deliberately done in an attempt to adapt the various parts of the program to the most favorable environment. The lecture rooms of Chicago University afforded the best atmosphere and facilities for scientific talks, while the campus of Northwestern University could not be excelled for the social features which formed such an important part of this meeting.

Council Meeting

The Council met at 4 p.m. Monday at the University Club, about eighty-five councillors attending and President NOYES in the chair.

The date of the spring meeting was fixed for the week of April 25, 1921. The proposal of the Chemical Society of London to enable members of the American Chemical Society to subscribe for the annual record of the Progress of Chemistry prepared by the Chemical Society and the Society of Chemical Industry

was referred to the secretary and the editor of *Chemical Abstracts* to arrange for subscriptions and deliveries.

Whether to hold the fall meeting in Pittsburgh or New York was left with the president and secretary with power to act. It is desired to make the meeting a joint one with the Canadian Chemical Society and the British or Canadian members of the Society of Chemical Industry in case this is possible, but this may only be concluded after a conference.

The invitation of the Federation of American Engineering Societies to attend its next meeting and to initiate plans for co-operation was declined. The resolution declining the invitation was unanimously recommended by the Advisory Committee, and the short discussion that followed was, with one exception, favorable to the resolution, and it passed. It was held that the Society should offer the Federation aid and encouragement in any manner it could, but that the fields of chemists and engineers were distinct and separate and that more and better work can be accomplished without interlocking the several organizations.

The editors of the various journals were re-elected, and vacancies on the associate boards were filled. The former editors of the Society's journal were severally elected to the post of editor emeritus.

The Pharmaceutical Division was changed in name

to the Division of Chemistry of Medicinal Products, with a view to making a clearer distinction between this Division and that of Biological Chemistry.

Dr. PARSONS reported informally on the meeting of the International Union of Pure and Applied Chemistry in Rome and was requested to give his report in full, already published in the *Journal of Industrial and Engineering Chemistry*, at the General Meeting on Tuesday morning.

It was resolved that the president appoint a committee of thirteen members, with Dr. Charles H. Hertzy as chairman, to represent the Society in co-operating with the Chemical Warfare Service of the U. S. Army in whatever manner they may be able. It is to consist of three members each representing research, development, production and physiological subjects.

The question brought over from the last (St. Louis) meeting whether or not the Society should meet but once a year at a general assembly, while other joint meetings of various sections be arranged according to geographic sections, brought forth extended discussion. It was lost by a large majority.

A resolution was introduced and unanimously adopted to the effect that hereafter it shall be expected of members and guests attending general meetings to bear a share of the cost of their entertainment, on the ground that the burden of expense assumed by the local sections which act as hosts is greater than is fair to ask of them.

ANNUAL DUES FIXED AT \$15

At 6:30 the Council dined as guests of the Chicago Section at the University Club, and after dinner continued in the dining room to consider the final question at issue, which proposed such change in the bylaws as to make the annual dues \$15 instead of \$10. There was considerable division of opinion, and for a time the air was thick with amendments, but President Noyes, after splitting them up into their component parts, succeeded in getting the views and votes of the councillors on every phase of the question, and in the end it was resolved by a large majority that the dues should be \$15 under the original resolution. The privilege of full membership and subscription to one of the society's journals for \$6 was extended to include graduate students as well as students; and under another resolution it was decided to allow students and graduate students a discount of one-third, making the net cost of membership and all three journals \$10, as before, instead of \$15. The definition of a student for the purpose of the two last resolutions was referred to the president for determination.

General Meeting

At the General Meeting in the Gold Room of Congress Hotel Dr. JULIUS STIEGLITZ, the Honorary Chairman, made an address of welcome, and so did JOSEPH R. NOEL, vice-president of the Chicago Chamber of Commerce. Mr. Noel said that in reducing the cost of the necessities of life chemists were humanitarians, and that the reduction of costs was the great problem of the day. President W. A. NOYES responded by emphasizing the obligations of chemists in reconstruction, observing that achievement is only possible in case they work together and unite in their efforts.

Secretary PARSONS made his report as requested at the Council Meeting on the meeting of the International Union of Pure and Applied Chemistry in Rome. As this

has already been printed in full details will not be given here except that the Union has resolved to meet in Poland in 1921, and that martial conditions may prevent this. The members would like very much to hold an annual meeting in the United States, but the current rates of exchange make the undertaking too expensive. It is planned to have general meetings once every three or four years in the place of the former triennial International Congresses of Applied Chemistry, of which the last was held in New York in 1912. An interesting note made by Dr. Parsons was the disposition of Europeans in international conclave to discuss details in general meeting rather than to refer them to special committees according to American usage.

The General Addresses were made by THOMAS E. WILSON, president of Wilson & Co., packers, and Dr. A. S. LOEWENHART, head of the department of pharmacology at the University of Wisconsin.

CHEMISTRY IN THE PACKING INDUSTRY

Probably no man eminent in business affairs has been so unhappily bespangled by the advertising writer as Mr. Wilson, and it was a great pleasure to find that despite the scarehead "studies" of him he is a gentleman at once simple in speech and habit, clear in vision, concise in his statements and persuasive in argument. He gave an outline of the incidence of chemistry in the packing industry, which he said had had its beginning and development within the life of the present generation. When he first went into the stock yards (and according to "Who's Who," that was in 1890), there was no such thing as a chemical laboratory there. The first laboratory was opened by H. W. Schmidt, now of Cincinnati, and the undertaking was generally regarded as a foolish experiment. The first thing Mr. Schmidt did was to install a vacuum pan to make extract of beef. It was not a laboratory apparatus, nor was making beef extract a laboratory operation, but Schmidt kept it there in order to show a credit from the operation of his laboratory in the only language that was effective. The profit on beef extract made it "pay" the while he was able to continue in research, and finally to achieve results.

In the early stages the packers were merely butchers on a large scale, and they could not offer for a live steer more than they could get for the beef. Today the sum realized for the beef is much less than the price paid for the animal that furnishes it. Chemistry has made this possible. The establishment of Wilson & Co. started a few years ago with but one chemist; today it employs nearly a hundred, and these are divided into analysts, research chemists, chemical engineers and commercial or business chemists. The co-ordination of science and technology in the packing industry made it possible to do what would otherwise have seemed impossible when the call came in February, 1918, to furnish 300,000,000 lb. of pork products per month for three months on pain of losing the war. There was actually shipped 9,000,000,000 lb. in February, March and April of that year, at a time when the country was in large part snowbound and the railways were nearly broken down.

Chemical research and control have enabled the packing industry to operate on a very low margin of profit. During the fiscal year of 1919 just closed the five large packers did a business of \$3,521,000,000 and made profits of \$34,500,000. They handled 40,000,000 head

of live stock at a profit of 89½c. per head, the profit on the turnover being less than one cent on a dollar.

Mr. Wilson pointed out that whereas we have heretofore striven for volume the time has arrived when we must conserve what we have and strive for improvements. It sounds well enough to say that they use everything in the pig except the squeal, but the fact remains that there is still great work to do in the science and more particularly in the chemistry of the industry of packing, that many fields are still undeveloped for lack of adequate research, and that it is the business of the men of today to attack them. Speaking for the industry with which he is connected, he said there are great opportunities open to the chemist, and he believes that there are in other lines as well. In conclusion he urged chemists to offer their work to business men in a language that business men can understand. He was sure that this could be done, and he hoped chemists would master the art of doing it.

CHEMISTRY IN BIOLOGY

Dr. Loewenhart followed with a discussion of chemistry in biology. Biology, he said, rests on three systems: chemistry, physics and on one part which is pure biology. The only process in biology that yields energy is oxidation, and after a discussion of oxidation in respiration he noted that fats, hydrocarbons and proteins oxidize at 37 deg. C. within the body, while outside it they are stable at this and higher temperatures. The explanation of the fact is found in oxidizing enzymes, of which the chemistry is at once very complex and very interesting, as well as full of unanswered questions. Why, for instance, does dextroglucose oxidize within the body, and why does not lævoglutose do the same thing? Again, oxalic acid and carbon monoxide will oxidize without the body, but within it they will not. All recent work on slow oxidation shows a great difference between it and combustion. It also shows that interference with biological oxidation starts different series of processes within the body which yield entirely different end products from those reached by normal processes. Such disturbances are caused by various chemicals and by temperatures that are abnormal. Another interesting question has to do with the relation of internal oxidation to the stimulation of an organ.

An important note is the similarity of oxidizing enzymes to organic peroxides. Most important antiseptic agents are oxidizing agents, and these are useful when they are not interfered with by proteins. Certain such organic oxidizing substances, if injected intravenously, increase the production of anti bodies, and decrease the inflammation, while remaining unaffected by the proteins. Therefore organic peroxides are very important, and new and better methods of preparing them are needed, as well as are new organic peroxides. Indeed, Dr. Loewenhart issued what was in effect a call for new organic peroxides from chemists, in the hope that they may aid in the conquest of disease. They must not be too active, and yet they must be active enough. And they should be water-soluble.

The notion still seems to prevail that there is a specific cure for every disease. It dies hard, but it is hoped to overcome the superstition in time. Now some excellent drugs were in use apparently before the beginnings of history—as we have it—and some began in religious ceremonies in connection with sacrifices to various deities. The co-operative study of drugs and

WALK BY THE LAKE, NORTHWESTERN UNIVERSITY CAMPUS

their effects, however, has had the surprising result that due to the activities within the Chemical Warfare Service we are better informed of the effects of a number of new substances than we are of medicines that have been in use over two thousand years. It was the co-operation of chemists, biologists and physiologists that made this possible.

In addition to his call for more organic peroxides, the speaker made a plea for real chemical training for those who are about to study medicine. It is, he held, almost impossible to superimpose chemistry upon the practitioner of medicine if he has not had the training beforehand; and he could even say the same thing of biologists. He has known only one who, having neglected chemistry in his academic years, went back and got it. Whoever would engage in research should first study chemistry.

TUESDAY AFTERNOON AND EVENING AT EVANSTON

At the conclusion of Dr. Loewenhart's masterly address the members ate an early luncheon and took special trains for Evanston, where the meeting continued on the campus and within the gymnasium of Northwestern University. Right here we desire to say—and we are likely to repeat it elsewhere—that the Chicago Section as hosts provided a rare welcome and entertainment for the members and guests of the American Chemical Society. In generosity, in careful and intelligent planning, and in grace, in charm, and—to apply an old meaning to a familiar word—in elegance, it has probably not been equalled in the history of the society. It would be hard to find a lovelier spot than the Northwestern campus on the lakeside. It was decorated with the colors of many universities and colleges, and few who were present will ever forget the beauty of the vision as they walked about before the afternoon session began in the Patten gymnasium. While the orderly arrangement could not have been brought about without complete team work on the part of the committee, it would be unfair to omit the special praise due to Dr. W. Lee Lewis, chairman of the Chicago Section and professor of chemistry at Northwestern University. There was not a hitch or a failure in the whole program. The only criticism that could possibly be

made was the heavy expense with which the Chicago Section burdened itself whereby it gave far and away more in the way of special trains and other pleasant conveniences than the Society could ask for or expect.

DR. TALBOT'S ADDRESS

At 3 o'clock President Noyes called the meeting to order, and Dr. HENRY B. TALBOT, of the Massachusetts Institute of Technology, delivered an address on "The Relation of Educational Institutions to the Industries."

Dr. Talbot believes that men of business have too little understanding of the responsibilities, the obligations and the opportunities of the professors. Occasionally business men appear at colleges and universities and occasionally they lecture, but usually they fail in this because they lack the talent of exposition. It is easy enough to talk about hand-in-hand work and co-operation between industries and educational institutions, but as soon as we undertake a realization of this we find that it means considerable change of routine, and often it involves expense. Therefore the effort is likely to be abandoned at about this point.

Now the community has a right to demand that young men shall be trained in abstract science and in public affairs no matter what their profession or occupation is to be, and this holds especially true of those who are about to enter industry. The present performance does not seem wholly adequate, and yet the speaker believes that the indictment lay less against the training and instruction than against the attitude of graduates.

In the monograph on technical education prepared by C. R. Mann for the Carnegie Foundation the requirements were set down in what was deemed to be the order of their importance. Here character, initiative, leadership and responsibility and a long list of native attributes were listed before technical knowledge, which stood seventeenth instead of first. Colleges cannot select their raw materials; they must make their selection from what comes to them. Character may be developed in a measure by the supervision of student activities, but the process is not always effective. In regard to the quality of leadership it often happens that the best young men are debarred by the self-assertion of others who are far less worthy. There are schools of business and engineering administration that are designed to provide training for leaders, but while the form is new

and it has promise, a difficulty lies in the selection of the right young men for these courses.

The atmosphere of a works is not and cannot be produced in a college. What the college tries to do is to arouse enthusiasm and eagerness to learn. The greater the effort a student makes to get his education, the greater as a rule is his appreciation of it. It is to be regretted that this ratio of appreciation to effort does not apply so frequently if the appreciation is expected of the student, in consequence of the efforts of his parents.

The speaker described the five-year course at the Institute of Technology that leads to the M.S. degree in connection with work done at the General Electric Works at Lynn, the Eastern Manufacturing Co. at Bangor, the Lackawanna Steel Co. at Buffalo, the New England Gas & Coke Co. and the Merrimac Chemical Co. at Everett. This course has already been described and discussed at length. It is open only to men of superior type who have already made good, and it has the distinctive advantage of revealing the practical value of "all that theoretical stuff," while it also trains men to handle others. There has been no trouble with the foremen and workmen in the works. They like it. The trouble is that many of the best young men cannot afford the five years.

Dr. Talbot made a plea for industries to take on for summer months the best students who are striving for the best education they can get but who are inhibited by the expense. It offers an excellent opportunity to get a line on a good man. Of course they are immature and occasionally they may be in need of a measure of forgiveness, but if we look back upon our own student days the chances are that we shall find traces of green paint there too. He made an urgent appeal for vacation positions in industrial works for good students.

Another point of contact which he believed might be developed with profit is the use of professors in research, not for problems of daily improvement and administration which are best worked out in the factory laboratory, but for special problems of a more abstract nature for which special training is necessary. He believed that this would also be of peculiar value to teachers, and that an occasional summer in the works would be of advantage all around. He concluded by an appeal to make use of members of college staffs as consultants, at all events until the supply of chemists is greater.

WALTER A. PATRICK, of Johns Hopkins, spoke briefly on the adsorption of vapors by silica gel, a special grade manufactured by the Davidson Chemical Co. of Baltimore being used. It was found that vapors of liquids of a high boiling point were more strongly adsorbed than those of low. Adsorption decreased with rise of temperature until the critical temperature was reached, where no adsorption took place. Full details of the theory and applications of adsorption were recently read before the A.I.C.E. and will soon be published in this journal.

The President was authorized to appoint a committee to revise the general programs of meetings of the Society with a view to providing more time for divisional papers.

As trustee of the body having in charge the collection and publication of physical and chemical contents Dr. JULIUS STIEGLITZ announced that this work was an obligation undertaken by the chemists and physicists of America and that the funds for the prosecution of it

SCENE ON NORTHWESTERN UNIVERSITY CAMPUS

were not yet collected. He urged upon members the need of providing funds for this purpose without delay.

It was also resolved to record the sincere regret of the Society that the dye bill failed to pass the Senate in the last Congress and that the urgent need of affirmative action in regard to it be taken at the earliest moment he communicated to the national legislature.

Entertainment and Reception

At the conclusion of Prof. Patrick's address the combined entertainment and reception began—from 4:30 to 10:30 at night. There was a concert by the Chicago Band on the lawn. About the campus at various tables punch was served by ladies of Evanston under the charge of Mrs. L. V. Redman and Mrs. W. L. Lewis. In the pool of the gymnasium, Tom Robinson, swimming instructor at Northwestern, gave an exhibition of swimming by his pupils, consisting of Evanston boys and girls that was as pretty a show as one could wish to see. It was more than that, it was a sight of memorable beauty to watch those lithe young bodies swimming and playing and racing—almost like so many

asking too much to expect one to leave. At 6 a supper was served by the ladies of Evanston at tables arranged for alumni of the various universities and their wives, and by 7:15 the great hall of the gymnasium was filled again. Here twenty-five members of the Chicago Symphony Orchestra led by Osbourne McConathy gave a beautiful concert at once popular and distinguished. Then followed some good chorus singing by everybody present, led by Mr. McConathy, and after a few monologues there followed Gilbert and Sullivan's old operetta, "Rox and Cox." The singers were well-known professionals, and the performance, with the Symphony Orchestra, went without a hitch and was delightfully rendered to its rollicking, cheerful end. Then special trains carried the visitors back to Chicago.

The Banquet

The banquet was held on Thursday evening in the Gold Room of the Congress Hotel. Dr. W. LEE LEWIS, chairman of the Chicago Section, presided, and he proved to be a witty toastmaster. The speakers were Raymond F. Bacon, Charles H. Herty, William A. Noyes,

SIXTIETH CONVENTION AMERICAN CHEMICAL SOCIETY BANQUET, CONGRESS HOTEL, CHICAGO, SEPT. 9, 1920

seals. There was also an organ recital in Fisk Hall by Hugo Goodwin, and of course there had to be a baseball game on the campus in which the Chicago Chemicos under Dr. L. V. Redman challenged All the World which (i.e., All the World) was led by Dr. Charles H. Herty. Dr. Edgar F. Smith was umpire.

While all these activities were in progress there was a dance provided on the second floor of the gymnasium, and here again we cannot forbear to mention the distinguished quality of the hospitality of the Chicago Section. Mrs. Redman and Mrs. Lewis had secured the presence of the young women of the best Evanston society to meet the chemists and the only objection raised by those present was that it was all too short.

From 4:30 to 5:30 a visit was made by a number of the more technically minded to the Evanston Filtration plant, but there was abundant excuse for all who did not go, because there was so much doing on and around the campus and it was so engaging withal that it was

Harrison E. Howe, William R. Moss, an attorney of Chicago, and Otto Eisenschiml. Listed among the speakers was Miss Margery Maxwell, soloist of the Chicago Grand Opera Company, who sang selections from operas and songs occasionally between courses, and interspersed among speeches afterward. Miss Maxwell's contributions had the same quality of eminent distinction that characterized the complete entertainment provided by the Chicago Section.

The speeches were short. Dr. BACON advised chemists to make themselves proficient as business men. Dr. NOYES emphasized the need of team work and ideals of service. Dr. HERTY made a plea for the dye bill. Major HOWE made a plea for better tools, among which the most important was the publication of tables of physical and chemical constants. Mr. MOSS wanted chemists to speak so that they could be understood by those who are not chemists, and Dr. EISENSCHIML told some profitable tales.

General Meeting, Industrial Division

CHARLES BASKERVILLE, of the College of the City of New York, reported that he has found several solvents for gaseous phosgene, among them gasoline, benzene and ethyl acetate, which dissolve about an equal weight of the gas at ordinary temperatures. These solutions do not have high vapor pressures, so may be transported with safety within ordinary closed containers. On exposure to the air the liquid and dissolved gas evaporate. By suitable distillation and rectification, the phosgene can be recovered from the solution in a pure state. The solutions of phosgene may find application as a rodent exterminator and offer a method of legally meeting the present railroad restrictions on the shipment of this poison gas.

ELECTROMETRIC METHOD FOR DETECTING SEGREGATION OF DISSOLVED IMPURITIES IN STEEL

EDWARD G. MAHIN, of Purdue University, gave an account of an electrometric method for detecting segregation of dissolved impurities in steel. If the hypothesis that steel acts to some extent as a solvent for segregation materials is correct, the electrode potential of the metal should be altered in the regions immediately surrounding the inclusion. It is not possible to determine this point by the usual method involving immersion of the specimen in an electrolyte, but a method was devised for exposing microscopic areas of metal surface to an electrolyte, so that the micro-electrode thus formed could be connected with a standard calomel half-element and the emf. of the system measured by the compensation method.

SODA-LIME FOR INDUSTRIAL PURPOSES

ROBERT E. WILSON, director of the Research Laboratory of Applied Chemistry, M.I.T., gave two papers. The first, on soda-lime for industrial purposes, was an outgrowth of work done in the C.W.S. for military use. Industrial soda-lime must have greater activity and capacity. It need not be so hard nor contain an active oxidizing agent, both of which requirements seriously limited the efficiency of military soda-lime. The factors determining the type of lime and the percentage of caustic soda solution to use were found to be the most important variables.

The flow of viscous oils through pipes, a crude asphalt base and a refined high boiling point paraffine base oil being used, was next discussed and Poisenille's formula found to hold, in the following form:

$$P = \frac{0.000668 \, z \, l \, v}{d^5} \quad \text{or} \quad \frac{0.000273 \, z \, Q \, l}{d^4}$$

where P = pressure drop in lb. per sq.in.

z = relative viscosity to water at 68 deg. F.

l = length of pipe in feet.

v = velocity of flow in feet-seconds in pipe.

d = inside diameter of pipe in inches.

Q = flow in gallons per minute.

A log log chart for converting Saybolt, Redwood and Engler time for efflux to relative viscosity was given having co-ordinates z /sp.gr. and seconds. The points (18, 100) and (1,500, 8,000) determined the Saybolt line. The pressure drop through a 90 deg. elbow in equivalent lengths of straight pipe in units of pipe diameter lengths was plotted against the ratio v/z .

H. K. BENSON reported that rosin extraction has been under a heavy handicap due to the retention of the solvents by the wood to an extent of as high as 25 gal. per cord. Two solvents offer more economical extraction costs, 5 per cent ammonium hydroxide and 70 per cent denatured alcohol solutions. When resinous wood of pulp size is treated with eight times its weight of 5 per cent ammonium hydroxide for ten hours, 94.5 per cent of the rosin is extracted. The ammonia extract decomposes slowly in the air at ordinary temperatures, and at 90 to 100 deg. C. is rapidly and completely decomposed, yielding ammonia vapor and finely divided humus in suspension. Ammonia extracted wood chips can be completely de-ammoniated by steam distillation. Denatured alcohol at 70 per cent strength is as efficient a solvent for rosin as ammonia, benzene, or gasoline.

REPORTS BY OTHER INVESTIGATORS

H. C. HOWARD, of the B. F. Goodrich Co., reported that certain arrangements of rubber balls were found very effective vibration absorbers.

HUGO SCHLATTER, of the Hercules Powder Co., confirmed Senderen's experiments on the action of aluminum sulphate in the manufacture of ether. Lead sulphate, broken porcelain, etc., were found to have the same action in aiding the formation of the vapor phase.

HARRY McCORMACK reported that benzene in motor fuel mixtures could readily be determined by bromene absorption. Evidently it is assumed that the petroleum fractions contain no double bonds, which does not seem justified.

W. D. COLLINS, of the U. S. Geological Survey, reported that the package committee recommended 500-g. containers for chemicals. R. M. WILHELM's report on standard thermometers and F. W. SMITHERS' specification on sulphuric acid were given.

O. L. BARNER, of Columbus, Ohio, spoke on the recovery of industrial vapors with activated charcoal. This material has been greatly improved since the close of the war and has much greater absorbing capacity than gas mask charcoal. It has proved excellent for the recovery of ammonia, sulphur dioxide, spent acid vapors, and solvents such as ethyl ether, gasoline, toluene, benzene, carbon tetrachloride, chloroform.

H. V. MAIN, formerly engaged in the manufacture of metallic arsenic with the Hoskins Process Development Co., described a nose dust respirator. Australian lamb's wool pads are held firmly over the nostrils by means of a guard made of packing rubber.

O. R. SWEENEY, of the University of Cincinnati, reported that a marked increase in the initial rate of hydrogenation of cottonseed oil with cobalt catalysts was found when over 10 per cent of hydrogenated fat was present. This indicated that the product of the reaction had some undetermined role in the reaction itself.

CHARLES L. PARSONS gave an account of a special study, which he had recently made while in Europe, of the application made there of ammonia oxidation for the production of oxides of nitrogen to be used in the manufacture of chamber sulphuric acid. In Germany this method was used almost exclusively, while in England about thirty plants have adopted it. About 20 per cent saving was obtained and such impurities as chlorine were not accumulated in the chambers, as in the ordinary niter process.

Physical and Inorganic Chemistry

R. H. BOGUE discussed the hydrolysis of sodium silicates, showing that the resistance to hydrolysis increases with the amount of silica in the compound.

H. H. WILLARD and R. K. MCALPINE made a final report on the revision of the atomic weight of antimony using carefully purified and fractionally distilled tribromide. The value obtained, 121.77, is considerably higher than the one given in the international table.

LOUIS KAHLENBERG showed how certain crystalloids like lithium chloride, silver nitrate or cane sugar could be separated from other crystalloids, including sulphur, camphor or naphthalene, using pyridine as solvent and a vulcanized rubber membrane. Any of the last three mentioned would be separated from any of the first three by passing through the membrane. In a similar manner it has been possible to separate certain colloids from certain crystalloids by having the colloids pass through the membrane.

HARRY N. HOLMS and W. C. CHILD described the action of gelatine in securing emulsions of water in kerosene. The stability of the emulsions was greatest for a definite viscosity which could be obtained either by using pure gelatine, by using less gelatine with a coagulating agent like sodium sulphate or by using more gelatine with a peptonizing salt of the type of sodium iodide.

Using electrometric titration, W. S. HENDRIXSON has been able to show that on titrating potassium dichromate against hydriodic acid there was no evidence of any superoxidizing power. Air has no effect on this titration.

W. D. HARKINS pointed out that the generalization of the ratio of one electron to two positive charges in the nuclei of most of the atoms would hold for that isotope of lithium having an atomic weight of 6.

ARTHUR E. HILL has found that silver perchlorate, a strong electrolyte, when shaken with water and benzene, is found to the very slightest extent in benzene in spite of its appreciable solubility, 25 g.p.l., in that solvent. This indicates that it exists as entirely different molecular species in the two solvents. On using solid salt in excess it is possible to cause the separation of a layer of liquid in this system. W. D. BANCROFT pointed out the probable existence of a large number of similar cases.

D. A. MACINNES, by multiplying together the ionic transport number, the equivalent conductance and the viscosity for solutions of the chlorides of hydrogen, potassium, sodium and lithium, obtained a constant value at 0.2 normal and 1 normal concentrations.

A. F. O. GERMANN has studied the cryoscopy of the systems of boron trifluoride with hydrogen sulphide, phosgene, sulphur dioxide, nitric oxide and hydrogen chloride. In each case one molecule of the trifluoride combined with one molecule of the other and in some cases evidence was obtained of the existence of an unstable compound between one molecule of boron trifluoride and seven molecules of the other.

ELLIOT Q. ADAMS pointed out a number of peculiarities of the actinium series which indicate that it may be of independent origin. A new name for the inert emanations of these three series, radon, actinon and thoron, was proposed.

A report was given of the progress of Dr. ACREE in the study of the hydrogen electrode with F. A. ELLIOT and Miss A. D. DUSHAK. By the use of combined

hydrogen-calomel electrodes the contact potential for solutions of potassium chloride has been determined and found to check the calculated value rather closely. To secure greater accuracy, more than one electrode can be used.

S. E. SHEPPARD and F. A. ELLIOT have found that the gold number has no connection with the quality of a gelatine. The great care in the making of gold hydrosols in order to secure a gold particle of uniform size was emphasized.

H. B. WEISER and ALLEN GARRISON have been studying the oxidation of phosphorus. When the current of air or oxygen is increased the rate of oxidation is decreased. On the other hand any increase in amount of phosphorus vapor increases the amount oxidized.

F. DANIELS has made a study of the thermal decomposition of nitrogen pentoxide and finds it to be a molecular reaction. From the velocity of the reaction the heat of the reaction had been calculated. According to the quantum relation using this reaction heat the pentoxide of nitrogen should be decomposed by infra-red light, $\lambda = 1.15 \mu$. Actually, however, blue light of much higher frequency is required. A possible explanation of this is that there is an induction period till some tetroxide is formed, after which the reaction goes more rapidly. It is possible that the lower oxide absorbs the blue light and re-emits it in the infra-red.

H. S. TAYLOR is carrying out some important studies on catalytic hydrogenation at Princeton University. The mechanism at the surface of the nickel catalyst has great technical interest.

In the study of the hydrogenation of benzene it had been found that at 180 deg. C. the formation of cyclohexane is complete, but at 300 deg. dehydrogenation sets in and carbon is formed. Dr. TAYLOR and G. DOUGHERTY showed that at 200 deg. an equilibrium is secured with 92 per cent cyclohexane. The velocity of the reaction does not fit the mass action law for three molecules of hydrogen, but does fit it for one molecule. In a similar way it had been noted that the reaction velocity for the oxidation of carbon monoxide in contact with quartz glass is proportional to the square root of the carbon monoxide concentration. These results tend to show that a catalyst may considerably alter the mechanism of a reaction. The final result, however, is probably not affected.

Cellulose Symposium

The program of the Division of Industrial and Engineering Chemistry opened on Wednesday morning with a second Cellulose Symposium, which had been organized in accordance with a vote passed at the St. Louis meeting. That the interest in the subject justified the action was demonstrated by the fact that nearly 200 members were present at the meeting.

REGENERATING BOOKSTOCK

The first two papers were directly in line with the motto of the Chicago meeting, "Increased Production Through Chemistry." The first of these was "Regenerating Bookstock," by CHARLES BASKERVILLE and CLARENCE M. JOYCE. The possibilities were pointed out of regenerating the chemically prepared pulp to be found in old magazines and books rather than using it for boxboard, roofing paper, etc. A new patented process for doing this was presented which consists in mechanically loosening and drawing apart the fibers

with as little tearing as possible. The ink is then "lifted" by treatment with borax, soap, kerosene and pine-oil. The pigment particles of the ink thus loosened are carried away in a subsequent washing.

RECOVERING NEWSPRINT

In the second paper, entitled "Recovering Newsprint," CHARLES BASKERVILLE and RESTON STEVENSON presented a novel method for completely de-inking newsprint stock containing a large percentage of ground-wood, with a minimum production of yellow color. The method depends on the use of American fullers earth suspended in the alkaline solution used for pulping and lifting the ink. The oils of the ink are adsorbed by the earth and the solid particles of ink adhere to it. The fullers earth is then washed away through a fine screen, leaving the pulp free from pigment and binder, and as clean as when first made.

CELLULOSE CONTENT OF VARIOUS COMPOUND CELLULOSES

In discussing "The Cellulose Content of Various Compound Celluloses," Prof. LOUIS KAHLENBERG presented results of experiments in which the cellulose content of various compound celluloses had been estimated by the ferric chloride hydrolysis method. Twelve different woods, nine straws, nine nutshells and two barks were investigated. Where comparable results have previously been published, the present results are of the same order of magnitude.

THE CONSTITUTION OF CELLULOSE

The most important paper of the symposium was on "The Constitution of Cellulose," by Prof. HAROLD HIBBERT. About an hour was devoted to the presentation of this paper and the considerable discussion which it aroused. Formulas which have previously been proposed by Tolens, Cross and Bevan, Green, Vignon and others were first briefly considered and the facts pointed out which any structural formula for cellulose should explain. The new formula which Dr. HIBBERT proposed explains all of these and some others. The formula follows:

A characteristic feature of the new formula is the presence of a primary alcohol group which the recent work of Denham and Woodhouse and of Pictet has shown to be present. Up to the present, work on the constitution of cellulose has been carried out chiefly along the lines of (1) "Hydrolysis," (2) Xanthogenate Reaction, (3) Acetolysis, (4) Methylation. The author has started work on the direct synthesis of cellulose by synthesizing

and outlined a method on which he is working for the

synthesis of mono-molecular cellulose. A new formula for starch was also proposed and the application of the new formulas was indicated in explaining the formation of dextrose, starch and cellulose in plants.

THE ACID HYDROLYSIS OF SUGARCANE FIBER AND COTTONSEED HULLS

In the absence of the authors, E. C. SHERRARD and G. W. BLANCO, the next two papers were presented by Dr. HAWLEY. In the first one, on "The Acid Hydrolysis of Sugarcane Fiber and Cottonseed Hulls," it was shown that by one method of treatment bagasse gave about 27 per cent xylose and cottonseed hulls 14 per cent; by a second method, bagasse gave 21 per cent figured on the dry fiber basis, and of this 57 per cent was obtained crystalline. It was pointed out that pentose sugars influence the equilibrium which is established in the conversion of cellulose to hexose sugars by hydrolysis. When present in sufficient quantity, they entirely prevent the formation of fermentable sugars. Attention was called to bagasse as a promising source of xylose or furfural.

HYDROLYZED SAWDUST AS A CATTLE FOOD

In the second paper "The Preparation and Analysis of a Cattle Food Consisting of Hydrolyzed Sawdust," results were presented indicating that a cattle food with a very considerable food value can be prepared by hydrolyzing Eastern white pine sawdust with sulphuric acid of 1.8 per cent concentration for twenty minutes at 120 lb. steam pressure. The average of twenty-nine cooks showed a yield of 18.85 per cent total sugars. The indications are that there are other digestible ingredients which have food value besides the sugars. Feeding experiments seem to justify further work and this is now being conducted.

A COMPARISON OF WOOD CELLULOSE AND COTTON CELLULOSE

Another contribution from the Forest Products Laboratory was "A Comparison of Wood Cellulose and Cotton Cellulose," by S. A. MAHOOD and D. E. CARLE. Samples of wood cellulose and cotton cellulose which had been subjected to various conditions of cooking and bleaching were analyzed to determine first, the best conditions for high yield of purified cellulose, and second, to determine points of similarity of difference in cellulose from wood and that from cotton. Munition linters were taken as standard and suggestions were offered for improving the yield of similar cellulose from wood. Acid cooking or acid and alkaline cooking are more effective for this purpose than alkali cooking. It was pointed out that since the results showed that cellulose from wood was a different chemical aggregate from cellulose from cotton, the practice of checking wood cellulose according to the specifications for cotton is questionable.

The next paper on the program had to be omitted owing to the inability of Dr. HUGH P. BAKER to be present at the symposium.

CELLULOSE MUCILAGE

In a paper entitled "Cellulose Mucilage," which was presented in abstract owing to the author's absence, Dr. JESSIE E. MINOR pointed out that recent work of Schwalbe and Becker confirms her theory that reactive,

insoluble, colloidal hydrocellulose is pure cellulose which has adsorbed dextrines formed by the hydrolysis of some of the cellulose itself. These dextrines thus adsorbed catalyze further hydrolysis, as does also hemi-cellulose or acid treatment of the pulp prior to beating. Use is made of this phenomenon in making parchment paper. The adsorbed dextrines assist in holding size, dye, coating, etc., but impregnation with metal weakens the strength of the resulting paper.

CELLULOSE SECTION TO BE FORMED

Following the formal papers, consideration was given to the advisability of forming a Cellulose Section, a number of those present taking part in the discussion. It was the unanimous opinion that both the importance of the cellulose industries in this country and also the interest in the subject manifested at the two symposia were sufficient to justify the formation of a Cellulose Section, and it was voted that the necessary steps should be taken for the formation of such a section.

Section of Sugar Chemistry

C. E. COATES, discussing the subject of "Refining Raw Sugars Without Bone Black," explained the important economic development which would be possible through the use of Louisiana sugar factories as refineries during the period of the year when not active for direct cane campaign. The use of bone black methods of refining in these plants is inexpedient, as the required extra investment would be considerable.

This author presented a large number of results from his own experience where various systems of operation had been attempted. Sulphatation, sulphitation, carbonation and direct filtration processes were all discussed. Yields were presented for these various processes under different circumstances, showing that with careful control returns which compare favorably with some refinery practice can be obtained.

Important results were reported particularly on the use of activated char. This material as prepared from rice hulls and other sources lends itself to frequent revivifying by washing and several reburnings at longer intervals. In one case thirty successful uses of certain samples of char seem to be entirely feasible. The use of kieselguhr was also discussed in this connection.

APPLICATION OF CLARIFIERS

W. D. HORN reported on the application of the Dorr classifier and the Williamson clarifier. The former apparatus, commonly used as a thickener for metallurgical slimes, lends itself also to the separation of insoluble materials from cane juices. A system of continuous subsidence and decantation of the clear liquor is accomplished, it is claimed, with very little inversion, the production of a clear juice, and a large fuel saving. The Williamson clarifier operates with violent aëration of the warm solution and subsequent skimming from the surface of the liquid in shallow pans of the scum thus collected. The skimming permits siphoning off of clear liquors and is reported to be very satisfactory.

SUGAR INDUSTRY OF FRANCE

T. H. MURPHY, discussing the sugar industry of France, reported interesting figures regarding the present status. Before the war 213 factories had sufficient output to permit exports of 80,000 tons per year. The present output of sixty rather small factories leaves a

deficit requiring import of 400,000 tons. It is reported that 142 factories were 85 per cent destroyed, particularly by removal of the copper equipment and the electrical apparatus and machinery. The damage is estimated by this author at \$89,000,000. Reconstruction is inevitably slow because of the very special equipment needs of the factories.

SUGARS IN BACTERIOLOGICAL WORK

E. H. EITEL discussed the application and availability of certain rare sugars for bacteriological work. These are applied particularly for the differentiation between different classes of bacteria, affording an important field where co-operation of chemist and bacteriologist is essential.

LABORATORY METHODS

Laboratory methods received considerable attention, especially by a group of papers presented by F. J. BATES and his associates in the sugar laboratories of the Bureau of Standards. C. A. BROWNE reported on a graphic method for estimating reducing sugars in the presence of sucrose. His charts will permit correction for dextrose figures between zero and 250 mg. in the presence of sucrose ranging from zero to 5 g. The same author discussed fully the chemical, physical, mycological and entomological characteristics of imported cane sugars.

He pointed out that the trend at present is to produce 96 deg. test sugar. There is some 98 to 100 deg. test imported for direct use and slight indication that more of this will be imported, especially if care and cleanliness are exercised in preparation of material suitable for direct consumption.

CHANGES IN SUGARS DURING REFINING

Discussing the changes in sugars during refining, A. F. BLAKE treated the relationship of Clerget values to plant processes and stages. He pointed out the importance of true sucrose determination in order to secure reliable information for plant and refinery control. The true percentage of sugar is not usually computed from polarization figures and one may be misled if this is not done, with serious consequences.

Division of Dye Chemistry

New Naphthalene Dyes, by A. S. WHEELER. When naphthalene is sulphonated to a disulphonic acid in the 1-5 position, then treated with NaOH and oxidized, a product called juglone is produced, and this, treated with bromine or with chlorine, gives a series of red, yellow and brown dyes that are very beautiful on silk. The colors range according to mordants—which are necessary only for shade—from red to brown and yellowish bronze. He suggested further coupling with azo compounds.

Applications of Maleic and Fumaric Acids and Their Salts in the Textile Industry, by J. H. CARPENTER, of The Barrett Co. These are now available in commercial quantities, and their uses are indicated as mordant assistants in chroming, in wool printing, in silk dyeing and finishing, increasing luster, and in certain blacks on cotton and in mercerizing. The acids are oxidation products of benzene in which vanadium is used as a catalyst.

The Education of the Research Chemist, by R. E. ROSE, of the du Pont company. The author pointed out that the dye industry of the United States represents

a large-scale experiment with men not experienced in the industry. He traced the education of the men so taken over in general, and expressed the belief that the educational system of the country was the best available to develop ingenuity, energy, etc., but that it was less effective in preparing for advanced research. Many failures were due to the fact that men experimented first and thought afterward, while the opposite is the rule of research. Another defect was the tendency to get quick results by hitting the high spots. Then all the valleys have to be laboriously filled out. Often, too, in industrial laboratories the quantities used in experiment were so large as to delay results. He was urgent in favor of training in history, English, etc., and a better grounding in the principles of physics and chemistry in preference to technology courses.

Dr. DERRICK, of the National Aniline Co., pointed out the peculiar value of group work in research, holding that two good men working together and helping each other are worth more than four good men working alone.

There followed several papers from the Color Laboratory of the Bureau of Chemistry at Washington on photo-sensitizing dyes, and one by C. R. SENSEMAN which bore on the production of resorcinol, as did also a paper by HENRY MCCORMICK, of Chicago, called "The

Extraction of Resorcinol From the Alkali Melt." Another paper by E. E. BRUNSKILL, of the Cincinnati Works (formerly Ault & Wiborg), discussed the Analids of Beta Oxy-naphthonic acid.

The Qualifications of Organic Chemists was presented by L. CROSSLEY, chief chemist of the Caco Works, in which he, like Dr. Rose (and both Drs. Crossley and Rose have had wide experience as professors of chemistry before entering into industry), felt that so-called utilitarian work was of least value, while training in general principles in those studies which are necessary for the meditations of thoughtful men was of leading importance.

The same author, together with C. B. OGILVIE and G. S. SIMPSON, described a circulating burette provided with temperature control for making quantitative analyses of amines and noting the variations in shade produced by the decomposition of coupled products. Also an agitator for long-continued stirring of volatile liquids. Dr. Crossley also called attention to the explosion hazard of naphthalene vapors in the presence of SO₂.

Reports of the meetings dealing with Leather, Fuels, Fertilizers and Rubber, and an account of the visits to the various industrial plants will be published in subsequent issues.

First Meeting American Society for Steel Treating

First General Meeting of Amalgamated Societies Held in Philadelphia—Exhibit of Heat-Treating Equipment—Excursions to Many Important Industrial Plants—Abstracts of Some Technical Papers Presented

DURING the past few months, a movement toward the amalgamation of the Steel Treating Research Society—the pioneer organization of technical men in hardening rooms—and the younger and more vigorous American Steel Treaters' Society has been effected. Overtures for this desirable step were commenced by Prof. A. E. WHITE, of the University of Michigan, who easily convinced the influential men in each society that much duplication of effort could be avoided, needed funds conserved, and better progress made in all respects should these two organizations cease their sharp competition for support. As a disinterested third party, he was thus responsible for the merger which was finally confirmed by an overwhelming letter ballot of each society. It was therefore fitting that he should be unanimously elected president of the new society, the American Society for Steel Treating, at its first meeting, held last week in Philadelphia. T. D. LYNCH, of the Westinghouse Co., and T. E. BARKER, of the Miehle Printing Press & Mfg. Co., are vice presidents, while W. H. EISENMAN, the energetic secretary of the American Steel Treaters' Society, will occupy the same, but enlarged position. Directors are HOWARD J. STAGG, Halcomb Steel Co.; E. J. JANITZKY, Illinois Steel Co.; W. C. PETERSON, Packard Motor Car Co.; and FRANK FAHY, consulting engineer, New York.

A very creditable exhibition of apparatus used in heat treating was held by the society at the Commercial Museum. Many firms manufacturing tool and alloy steel; furnaces, refractories and fuel burning equip-

ment; pyrometers and physical testing machines; quenching oils and carbonizing compounds displayed their lines, and were visited by many society members and guests. Some of the exhibits contained full-sized equipment in operation, a fact which influenced the comfort of the occasion materially. A dozen large gas furnaces produce more or less noise and considerable heat; the heat could be endured by most of the men—it felt like home—but the noise detracted very materially from the technical sessions: often it was absolutely impossible for the speakers to be heard by those at the rear of the hall. Yet despite this regrettable fact, the eight technical sessions were quite well attended and the papers were followed with extreme attention. Several of the more interesting contributions are abstracted on the following pages.

Messrs. SAUVEUR, RICHARDS and VAUCLAIN formed the attractions at the banquet. Dr. RICHARDS spoke on "The Ancient and Honorable Art of Steel Treating" and cited evidence to support his view that iron and steel were discovered even earlier than bronze. By virtue of his skill in making tools and weapons the smith and armorer have always held a most honorable position among craftsmen. Dr. RICHARDS, together with Prof. SAUVEUR, ventured the hope that the new society would add much luster to the ancient prestige by adding newly discovered science to the heat-treaters' equipment. Prof. SAUVEUR even went further in citing the fact that whereas steel-metallurgy has been revolutionized in the last three centuries by the labors of a galaxy of French

and English masters, the efforts of Americans have largely been confined to the introduction of grand labor-saving devices, and the procurement of tremendous tonnage. Yet the new society, in emphasizing quality as its prime aim, should have a great influence in the future development of substantial advances in steel metallurgy; an advance which is pacing civilization.

Some of the Technical Papers

HEAT-TREATING SMALL ALLOY STEEL PARTS

A method of heat-treating small high-carbon or chromium-vanadium steel parts in quantity for maximum hardness and strength was described by R. L. GILMAN, of the Standard Steel & Bearing Co. He uses three rotating tube furnaces, connected in series, with the necessary quenching tanks and conveyors between, so that the operation is continuous and requires no manual labor. The furnaces are gas fired, with automatic regulation for close temperature control. Parts are charged into the cold end of the carburizing furnace at the rate of 150 lb. per hr., together with crushed charcoal. These work their way forward so that at the end of 30 min. they attain a low red heat. A mildly carburizing atmosphere is maintained by illuminating gas from municipal mains. Gradually the pieces attain about 1,600 deg. F., and at the end of two hours drop out of the end of the furnace into circulating oil. A conveyor quickly removes them at a smoking heat to boiling soda solution for cleaning, and thence to the hardening furnace at a uniform temperature. This furnace is heated to a considerably higher temperature (1,750 deg.) than the piece attains, owing to its short stay—6 or 7 min. is sufficient for $\frac{1}{8}$ -in. work to reach the hardening temperature superficially. Quenching and annealing follow, a similar furnace practice being used. Small pieces of correct shape, such as many bearing parts, may be safely treated in this manner, which gives extreme uniformity of surface hardness and finish. Subsequent operations may proceed with sufficient precision and speed to pay amply for the long carburization period.

HEAT-TREATMENT OF CHROMIUM-NICKEL STEEL SPINDLES

Details of the heat-treatment given chromium-nickel steel spindles for automatic screw machines were given by H. B. SMITH and F. J. OLCOTT, of the New Britain Machine Co. S.A.E. Steel 3440 (Fig. 1) is delivered in $5\frac{1}{2}$ -in. rounds, and forged to $3\frac{1}{2}$ in. at temperatures from 2,000 to 1,600 deg., giving the microstructure of Fig. 2 after air cooling. Four thousand pounds of forgings

is then loaded into a car-type furnace at 600 deg. F., and in twelve hours is heated to 1,600 deg. Doors are then opened and the charge removed after it has cooled to 600. Annealing is done in a similar furnace. Seven hours is required to reach 1,380 deg.; the furnace is then sealed, and in four hours has dropped to 600 deg., when the charge is removed. Maximum allowable Brinell hardness is 200, and the structure is as shown in Fig. 3. After machining into a hollow tube $3\frac{1}{2} \times 32$ in., with $\frac{1}{8}$ -in. walls, the spindle is hardened in a lead pot, 8 in. diameter by 54 in. deep, containing 450 lb. lead at 1,400 deg. F. One spindle is immersed, lowering the lead to 1,375, which temperature gradually increases, reaching 1,400 in 10 min., when the spindle is oil quenched. Drawing is done in an electric furnace at 400 deg. F., automatically controlled to within 7 deg. plus or minus, 80 min. being required. Fig. 4 reproduces the structure; minimum hardness is 418. Finish-grinding with a soft wheel, slow feed and plenty of water will produce no soft spots, in fact total rejections over a period of two years amount to but 1 in 700. Hardening warps some pieces as much as 0.05 in. out of line; this is corrected under a press, but is a feature which requires further study for its elimination.

HARDENING TRACTOR WORMS

J. L. MCCLOUD described some interesting results obtained at the Ford Motor Co. in the routine of hardening tractor worms. As a result of preliminary work on rather an extensive scale, they became convinced that the best combination of machining qualities, high physical properties, ease in heat treatment and grinding could be had from oil-hardening gear stock (carbon 0.42 per cent, Mn 0.85, Cr 0.90, Ac 1,450 deg. F., Ar 1,280 deg. C.). By the use of a continuous furnace the annealing and normalizing time was reduced from 12 hr. to 2 $\frac{1}{2}$ hr.; the furnace, although only three times as large as the intermittent type, handles six times the work, or 1,900 lb. per hr. Normalizing consists in bringing the steel to 1,575 deg. F., where it remains long enough to relieve all forging strains and to place all carbide in solution; then it is cooled at a definite rate just below Ar, then quenched in boiling water. Machinability is found to be a function of the Brinell hardness, which is therefore held between 179 and 207. After finishing, the gear is heated in a salt bath (50 per cent Na₂CO₃, 37 $\frac{1}{2}$ per cent NaCN and 12 per cent NaCl). It requires 10 min. to reach 1,540 deg. C.; after remaining 6 min. longer it is quenched in oil; the resulting Brinell hardness is about 500, both at edge and center. Its ductility, however, is low—the elastic limit and ultimate are prac-

Fig. 4. Finished spindle.

tically the same. If now the hardened steel worm is plunged into another salt bath at 1,470 deg. F. for 12 min., its temperature at the center will reach 1,375 deg. F.; upon second quenching the hardness in the tooth section will still be 500 but at the center it is reduced to 340, while the ductility is immeasurably improved (e. l. 60,000 lb., ult. 100,000+ lb.).

QUENCHING MEDIUMS

V. E. HILLMAN, metallurgist of the Crompton & Knowles Loom Works, discussed "The Efficiency and Applications of Various Quenching Mediums." He defined the main useful characteristics of oil to be five: First, the hardening efficiency, measured by the Brinell number of a coupon after quenching from a proper temperature; second, the quenching uniformity, or the production of substantially equal hardness despite material variations in oil temperature; third, the viscosity, which as it increases, increases the difficulty of circulation and reduces the hardening efficiency; fourth, the flash point, which must be high from a safety standpoint; and fifth, the permanency under constant use. While practically all oils when used as quenching baths act in the same way when new, when maintained at a uniform temperature, and when used as a still bath, animal oils in general have a good hardening efficiency, but deteriorate rapidly in use and vary much in quality shipment to shipment. Vegetable oils also give good hardness, but are liable to deteriorate through oxidation. Mineral oils, while subjected to some fractional distillation in continuous quenching duty, are excellent in service not too severe. Compounded oils of good repute are on the market which overcome many of these difficulties.

PEACE-TIME USES OF WAR-TIME LESSONS

A clear account of some "Lessons Learned in the Manufacture of Munitions and Ordnance That Can Be Applied to the Peace-Time Pursuits of Industry" was given by F. V. LARKIN, head of the department of mechanical engineering, Lehigh University. Tracing the manufacture of projectiles and gas cylinders from the furnace to the finished state, he remarked that if the furnace operators will compile an accurate history of every open-hearth heat, many mysterious "off-heats" may be easily explained and become much less frequent. Proper attention to pouring, giving a smooth, clean surface on the ingot, followed by careful rolling-mill practice will reduce chipping or grinding of surface defects in the blooms down to zero. Pyrometric control of forge furnaces gives more uniform heat, reducing wear on tools and the number of rejections. Heat treaters should know enough about pyrometers to regard them as aids in their work rather than telltales. Time was demonstrated to be an important factor here—continuous furnaces were operated on the stroke of a gong, effecting remarkable results in volume and quality of production. Turning to the human side of the work, Prof. LARKIN emphasized that with the right spirit in a new organization, the existence of unknown trade secrets is a spur to accomplishment rather than a handicap, and he knew of no secret process which could not be bettered by proper study and execution. Specifications, too, if properly drawn and fairly met, cannot but work to the advantage of the workmen, establishment and product. Never ask a customer whether a product will do. Know that it is right, and then he will have to take it.

MANUFACTURE OF STAINLESS STEEL ARTICLES

Certain metallurgical features of the manufacture of stainless steel articles were given by W. H. MARBLE, manager of the American Stainless Steel Co. An analysis of C 0.20 to 0.40 per cent, Cr 13 per cent, Si 0.30 per cent and Mn 0.50 per cent has been all but standardized. Carbon must be above 0.20 per cent for necessary hardness, yet not above 0.40, else difficulty will arise in forging. Silicon tends to neutralize the hardness of carbon, yet enough should be present to insure soundness. Chromium is the essential element furnishing the peculiar resistance to corrosion, tungsten and nickel being sometimes added for an increasing luster in polish. Freedom from corrosion is independent of the surface shape and smoothness as long as it is clean and not cold-worked. In practice, however, a polished surface insures cleanliness. Stainless steel is manufactured much like high-speed steel. Ingots are box-annealed at 1,380 deg. F., air-cooled, reheated to 2,100 deg., and hammered carefully, never allowing the temperature to drop below 1,650 deg. F. Cooling after forging gives hard material, the higher the uninterrupted cooling the harder. Rough forgings are now re-annealed at 1,380 deg. F., using all the precautions necessary for high-grade steel; furnace-cooled to 1,100, and then air-cooled—resulting in Brinell hardness, 200. After machining and finishing the piece may be hardened from 1,750 in air, oil or water, depending upon the intricacy of the shape, and tempered at a suitable heat, varying from 280 deg. F. for knife blades to 1,100 deg. F. for exhaust valves. One early trouble in using this material in the cutlery trades occurred here, since the temper colors appear at approximately twice the temperature indicated by plain carbon steels.

HELICAL SPRINGS FOR HEAVY DUTY

Unusual springs of particularly heavy duty are required to transmit the power from a motor-driven quill, through a flexible coupling to the driving wheels of heavy electric locomotives. T. D. LYNCH, of the Westinghouse Co., presented a tentative specification for manufacture of such helical springs, or indeed, for higher grade locomotive springs than those now available.

He favors an analysis as follows:

Carbon	0.50 to 0.60
Manganese	0.60 to 0.80
Silicon	1.90 to 2.20
Phosphorus	0.04 Max.
Sulphur	0.04 Max.

It should be made by crucible or electric furnace, cast in 9-in. ingots with smooth surface, free of surface blemishes. Such steels must be reheated very slowly; rolling temperature is 1,100 deg. C. After careful reduction to 3-in., the billet is cooled, cropped thoroughly, and any surface defect chipped or ground out. Reheat to 1,100 deg. C., roll to size (in this case 1 in. \pm 0.025), shear, cool, inspect and carefully bundle so that no scratch or nick may mar the finished surface. In spring making, the rods are coiled on a hot mandrel after heating to 925 deg. C. Allow no water to come in contact with spring or mandrel; notch for length at a dull red heat, cool slowly and uniformly. All operations should guard against producing the slightest surface damage. Recommended heat treatment: preheat to 700 deg. C., soak at 900 deg. C., quench in light oil; draw in salt bath at 455 deg. C., and finally clean in a hot soda wash, followed by an oil dip to prevent corrosion. Bri-

nell hardness should be between 375 and 450; structure troostitic or troosto-sorbitic; tensile strength 200,000 lb. per sq.in. or more. The specification covering reaction under load depends upon the use to which the spring is to be put.

HIGHLY RESISTANT ALLOY STEEL

CHARLES M. JOHNSON, director of research department, Crucible Steel Co., described the "Properties and Microstructure of Heat-Treated Non-Magnetic, Flame-, Acid- and Rust-Resisting Steel." The analysis was not given, but the statement was made that the carbon was 0.3 to 0.4, and micrographs of ingot structure indicate it to be a complex alloy which reverts to a homogeneous solid solution upon annealing at 1,300 deg. C. (Brinell 160), and upon very long-continued tempering—a matter of days—allows an excess constituent to divorce itself and become spheroidized. It is quite non-magnetic—its residual magnetism after charging did not exceed four lines per sq.cm. It resists staining and rusting remarkably; the resistance to corrosion being compared with other well-known steels as follows, the figures representing loss in grams per sq.in. in 24 hr.:

	Glacial Acetic	10% H_2SO_4	32% HNO_3	19% HCl
New steel....	6.1	3.2	0.4	
Monel metal...	0.7	1.3	soluble	
High Cr-Si steel	0.0	soluble	0.5	
38 per cent Ni steel	13.8	4.1	soluble	19.0
High Cr steel...	0.7	soluble	0.1	soluble

Approximate physical results on the new steel are as follows:

	E. T.	T. H.	Elong.	Reduc.	Brinell
Heated 5 in. at 2,400 F.	90,000	120,000	30	45	230
Quenched in oil from 2,000 F.	60,000	110,000	50	60	200

Although the metal can be forged, rolled or sheared in thicknesses 0.1 to 1 in., and is machinable, it offers a maximum resistance to prolonged heating at temperatures up to 2,000 deg. F. and is cut by the oxy-acetylene torch with the utmost difficulty.

BLADES FOR POWER SHEARS

Aside from the hand and machine tools required in their extensive shops, a modern steel plant requires much tool-stock for shear blades and pneumatic chisels, the latter for chipping surface defects from high-grade billets. GEORGE PORTEOUS, of the Minnesota Steel Co., called attention to the fact that a high-grade open hearth steel analyzing C 0.90 to 1.00, Mn 0.30 to 0.40, Si 0.02, P 0.01, S 0.03, can be used successfully for such service with better economy than crucible or alloy steels costing at least four times as much. He described in his paper precautions to be observed in the forging and hardening of pneumatic tools, drills, taps and reamers. Fig. 5 shows some of the tools, as well as two pairs of shear blades, the larger for billets and the smaller one for rounds. A pair of the latter were exhibited and were in excellent shape, even after having cut 20 tons of cold 1½-in. rounds of 1.20 carbon, 0.70 manganese steel. These blades are carefully forged, furnace annealed at 1,475 deg. F., machined and hardened at 1,450 deg. by quenching in water to harden the surface, then transferring the still hot piece to oil. Drawing temperature is 490 to 500 deg. F. If the bolt line through the center of the blade is kept tough by protecting with bolts, washers and strips during the heat-treating operations, as shown at the right of Fig. 5, no breaks at this weak section will occur either during fabrication or service.

FIG. 5. TOOLS MADE OF OPEN-HEARTH STEEL.

CYANIDE HARDENING DUE TO NITROGEN

G. R. BROPHY and S. B. LEITER, of the General Electric Co., have discovered that whereas pearlite due to carbon and pearlitic structure due to nitrogen are indistinguishable after picric or nitric acid etching, STEAD's cupric reagent darkens the former very slightly but turns nitride black. Using this test, cyanided cases were found to contain much nitrogenized material. They therefore conclude that absorption of nitrogen is responsible for the properties of articles case hardened in cyanide, as well as the carbon, which latter had formerly been thought the preponderating cause. If a bar containing 0.04 per cent carbon be immersed four hours, the resulting surface will analyze only 0.33 per cent carbon, yet it will easily resist a file. Quenched 30-point steel Brinells 207, but the cyanided bar is hard to file even after annealing. Further confirmation of the authors' ideas is found in the fact that if a cyanided case be ground off, the rod is still very brittle, and remains so after ordinary annealing.

Acknowledgment

Through an oversight in the article on "Problems of the Petroleum Industry," by William A. Hamor, page 425 of the Sept. 8 issue, we failed to acknowledge the courtesy of the Petroleum Iron Works Co., Sharon, Pa., in supplying the author with photograph reproduced in Figs. 2, 3 and 4, illustrating stills and agitators manufactured by that concern.

Studies in Evaporator Design*—IV

An Investigation of the Boiling Points of Salt Solutions—Critical Examination of the Vapor Pressure and Temperature Data Given in the Literature, Checked by Determinations—Charts and Tables on Salt Solutions

By W. L. BADGER AND E. M. BAKER

AS A part of the extensive program of research, undertaken in the Evaporator Experiment Station of the University of Michigan, on heat transmission in evaporators and the various factors affecting evaporator design, a study is being made of the loss in effective temperature drop between heating steam and boiling liquid, due to excess boiling point of the solution being evaporated. To this end it has been found necessary to attempt to collect all possible data on vapor pressure-temperature curves at varying concentrations of the more important chemicals recovered from solution in the industries, and where information is not available or is of doubtful value, to determine the necessary data in this laboratory. This paper particularly concerns an investigation of such curves for sodium chloride, and a critical review of such data contained in the literature.

ELEVATION OF BOILING POINT WITH SALT CONCENTRATION

In the design of an evaporator installation, it is necessary to know the "excess boiling point" of the solution being evaporated in each effect, at the temperature and pressure existing in that effect, in order to be able to calculate the heating surface required in any given case. This so-called "excess boiling point" is merely the elevation of the boiling point of the solution over the boiling point of pure water at the given pressure. The difference between the temperature of the steam supplied to the evaporator, t_1 , and the temperature of the vapor coming from the solution, t_2 , may be divided into three parts:

- Loss of effective temperature drop due to the excess boiling point of the solution.
- Loss of effective temperature drop due to the effect of hydrostatic head.
- Temperature drop available to cause heat transference from the steam to the boiling solution.

Hence, the available or effective temperature drop may be much less than the total temperature drop, since $c = (t_1 - t_2) - (a + b)$.

For example, a saturated solution of NaCl will boil at 108.7 deg. C. under a pressure of 760 mm. mercury, while water boils at 100 deg. C. If steam at 115 deg. C. were used to cause evaporation of water, and also of a saturated NaCl solution, in evaporators operating under 760 mm. pressure, there would be an effective temperature drop (neglecting for the moment the hydrostatic head losses) across the heating surface of only 6.3 deg. C. in the case of the salt solution, as compared with 15 deg. C. in the case of water or a solution that does not have an excess boiling point. Moreover, the heat transmission per degree temperature drop per square meter of heating surface will be much less the smaller the temperature drop.¹ The excess boiling

point represents a loss of temperature drop, which means loss of evaporator *capacity*, not of thermal efficiency of the set of pans.

DIRECT DETERMINATIONS REQUIRED

While the literature shows a large number of determinations of elevation of the boiling points of aqueous solutions, many of these are for dilute or only moderately concentrated solutions, or are at atmospheric pressures. On critical examination, many of the values given are found to differ widely. Hence this laboratory has undertaken the rather ambitious program of exam-

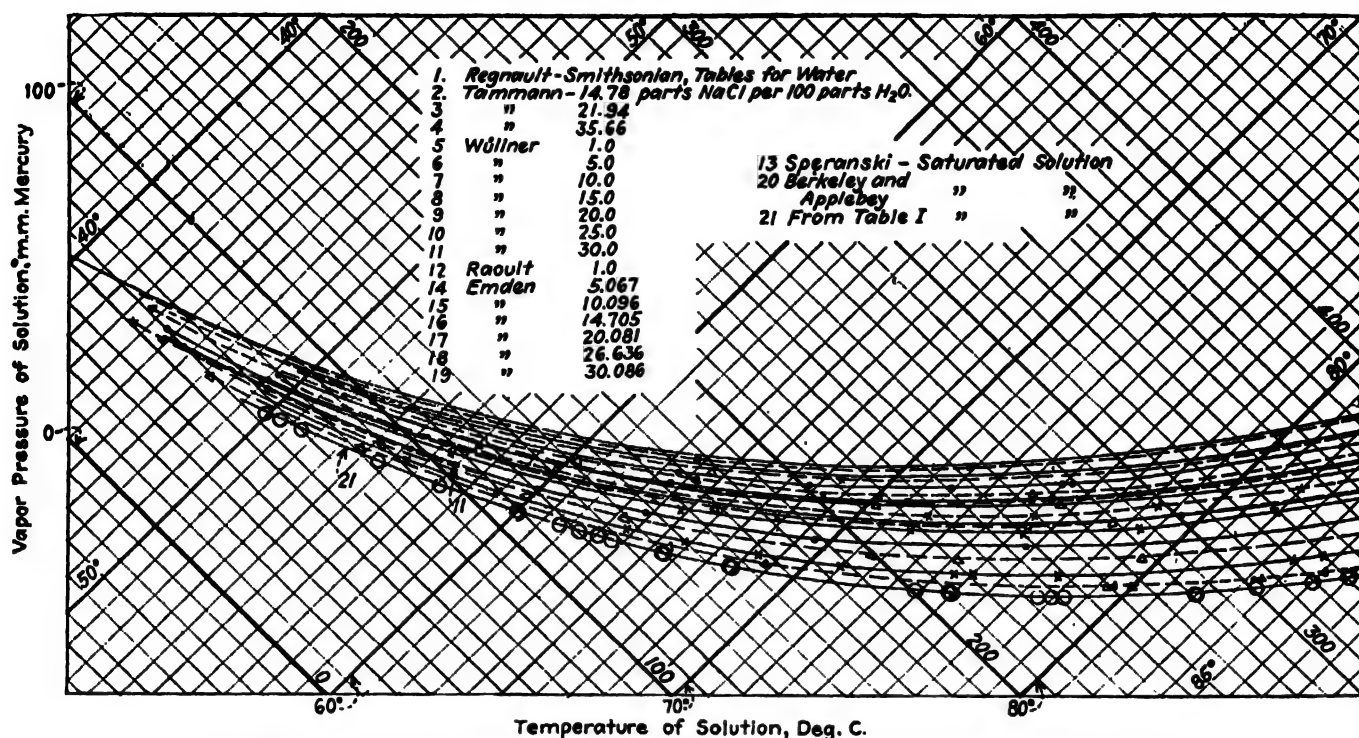

FIG. 1. BOILING-POINT APPARATUS

ining the values given in the literature, and of making such determinations as may be necessary to prepare tables of sufficient range and accuracy for the purpose of evaporator design.

*Read before the American Institute of Chemical Engineers, Montreal, June 29, 1920.

¹See "Studies in Evaporator Design—I," CHEM. & MET. ENG., vol. 23, No. 6, Aug. 11, 1920, p. 237. The relation of temperature drop and temperature level to heat transference in the vertical tube evaporator.

CURVE 1. VAPOR PRESSURE OF NaCl SOLUTIONS AT VARIOUS TEMPERATURES

The first problem to be studied has been the excess boiling point of sodium chloride solutions. This was taken up with the intention of later testing our theories by actual test on salt pans regularly in operation.

It should be pointed out here that it is impractical to calculate elevation of boiling point or depression of vapor pressure from the physicochemical considerations. Many of the laws, as Raoult's, hold rigidly only for ideal solutions. Equations and formulæ have, however, been advanced which attempt to take into consideration all the factors involved, but these, at least from the engineering standpoint, are impractical. It is evident that for exact application of such formulæ a knowledge of the degree of dissociation of the solute and of association of the molecules and ions of the solute with the solvent must be known over the entire range of concentrations and pressures. Much of the theoretical work has attempted to establish a quantitative relationship between the boiling points of solutions and osmotic pressure. Some excellent work of Dr. Orin E. Madison on the theory of osmosis, not as yet published,¹ shows that such relations cannot be expected to hold rigidly in the case of electrolytes. It therefore seems unprofitable to go into a theoretical discussion of these factors in this paper, but a bibliography of articles dealing with this question and methods of determining boiling points is appended.

The direct determination of the vapor pressure of the solution under the desired conditions of temperature and pressure either by the static or ebullistic methods is far more satisfactory than an attempt to get at it from theoretical considerations or empirical formulations.

The work on sodium chloride was therefore divided into two parts: first, a determination of the boiling point of saturated sodium chloride solution over the temperature range 50 deg. C. to the boiling point at 760 mm. pressure, to supplement the values found in the literature, and second, a critical study of the values given for the boiling points (or vapor pressures) of

salt solutions of various concentrations over the range of temperatures and pressures employed in evaporator practice.

BOILING POINT APPARATUS

Several types of boiling point apparatus were experimented with, but the apparatus finally used is shown in Fig. 1. The drawing is nearly self-explanatory. A saturated solution of sodium chloride, together with an excess of salt, was placed in the 2-l. flask A, which was protected from radiation and air currents by a layer of asbestos $\frac{1}{2}$ in. thick, molded onto the flask. The solution was heated by the small electric heater B. The amount of heat input, or rate of boiling, was regulated by varying the current by means of an external resistance in series with the heater. The vapor passed up around the thermometer through the tube C, which was also protected with asbestos covering, except at the point where temperatures were being read, thence to the trap D and the condenser E. All condensed water was returned to the flask at the base of the heater by the tube F. By thus steam-jacketing the thermometer, the steam correction to the reading taken was reduced to 0.12 deg. C. for the maximum correction for the temperature of the emergent stem. The vacuum was measured by the U manometer M which communicated directly with the flask, thus measuring the pressure at a point very near the thermometer bulb. The importance of this precaution is well shown by E. von Rechenburg.² The vacuum was maintained and regulated by means of an ordinary laboratory water jet vacuum pump. In this way it was possible to hold the vacuum steady within 1 to 2 mm. for periods of over 30 min., during which a number of simultaneous readings of vacuum and temperature could be taken. The vacuum readings were corrected for the temperature of the mercury, before subtracting from the barometer to give the absolute pressure. The thermometer used for the readings below 100 deg. C. was graduated in tenths of degrees, and the thermometer

¹By personal communication.

²J. prakt. Chem., vol. 79, p. 475.

CURVE I (CONTINUED). VAPOR PRESSURE OF NaCl SOLUTIONS AT VARIOUS TEMPERATURES

used for the higher temperatures was graduated in fifths of a degree. These were both certified thermometers, which had been rechecked at the boiling point of water. It should be remembered that the values were wanted for engineering design, and that an accuracy of 0.1 deg. C. or 2 mm. of mercury would be amply accurate for this purpose.⁴ The values so obtained are given in Table I. This table also includes some values obtained with essentially the same apparatus, but with different methods of heating. In one case the heating was done by a small copper coil placed in the solution and heated by means of steam, and in the other case direct heating by a gas flame was used.

THE LITERATURE ON VAPOR PRESSURES AND BOILING POINTS

The study of the values given in the "standard" tables and scattered through the literature was carried out as follows: The data could be separated for the most part into two divisions: (a) the vapor pressure of certain NaCl solutions over a range of temperatures, and (b) the boiling point of various NaCl solutions at 760 mm. pressure. Curves I and II were then plotted on a very large scale. Curve I shows the value given for the vapor pressure of NaCl solutions over a range of pressures. Values below 50 deg. C. were discarded as not being pertinent. Smooth curves were drawn through the points given by each investigator. Our results for saturated sodium chloride solutions were included in this graph. From Curve I a table was made up showing for each 5 deg. interval, from 50 to 100 deg. C., the concentration of sodium chloride and the corresponding vapor pressure given by each investigator.

Curve II shows various concentrations of NaCl solutions plotted against their boiling points under 760 mm. pressure. Some of the points at the same concentration

⁴Many values given in the literature were found to differ by two full degrees C., even though pressures were expressed in hundredths of millimeters and temperatures in thousandths of a degree.

⁵The values given by Droop Richmond, Gmelin-Kraut, 7th ed., vol. 3, p. 359, should be for per cent NaCl instead of g. NaCl per 100 g. H₂O.

CURVE II. BOILING POINT OF NaCl SOLUTIONS AT 760 MM. PRESSURE

showing grams NaCl dissolved by 100 g. H₂O at various temperatures as given by different investigators. A smooth curve was drawn, and this curve was taken as giving the true solubility of NaCl in H₂O. Values read from this curve are given in Table II. These values were also plotted on Curve II, and a smooth curve was then drawn through the values previously plotted, and extending just up to this solubility line. In drawing Curves II, III and IV an effort has been made to weight the values according to the care, accuracy and date of the original investigations.

VAPOR PRESSURE OF SALT SOLUTIONS

Curve IV was next plotted from data obtained from Curves I and III. That is, for each 5-deg. interval, from 50 to 100 deg. C., the vapor pressures of solutions of concentrations ranging from pure water to saturated solution were plotted against the corresponding concentrations. The concentration for the saturated solutions was taken from Curve III. The 100 deg. C. curve was supplemented by values given by Tammann for the vapor pressures of salt solutions at 10 deg. C., these data being plotted as solid circles. Smooth curves were drawn through these points, thus giving mean values for the vapor pressure of solutions of various concentrations at 5 deg. temperature intervals. Table III, showing the

CURVE III. SOLUBILITY OF SODIUM CHLORIDE

vapor pressure at these temperatures of solutions of various concentrations, was then made up by reading values from Curve IV. Table IV, derived from Curve II, shows the temperature at which solutions of various concentrations have a vapor pressure of 760 mm. From these values Curve V was plotted, which shows the vapor pressure, at different temperatures of water, of solutions containing 4, 8, 12, 16, 20, 24, 28, 32 and 36 g. NaCl per 100 g. H₂O and of saturated NaCl solution. It is noteworthy that smooth lines, conforming in curvature with the curve for pure water, could be drawn through every point so plotted. From this it is inferred there could be no great error in the values given by either Curves II or V.

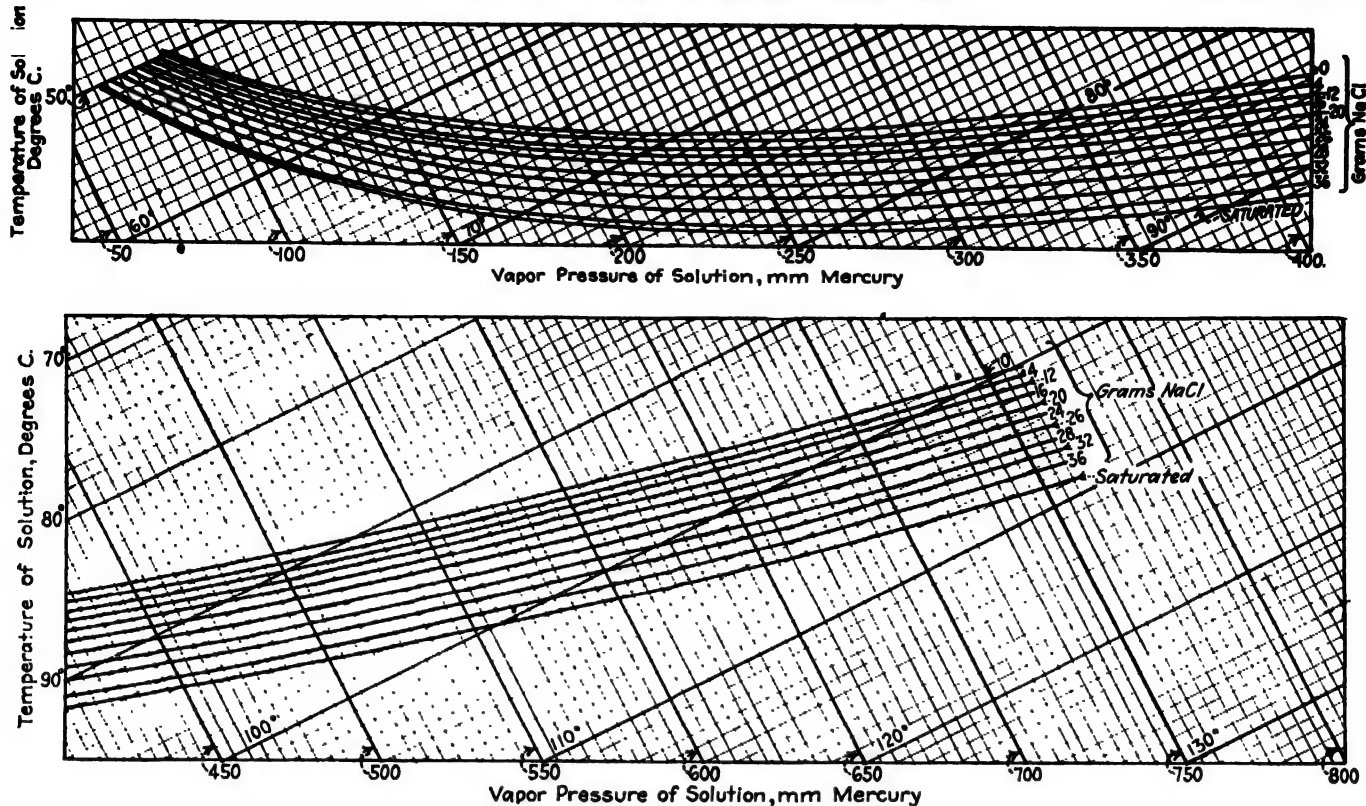

TEMPERATURE HEADS

Curve V is useful in giving a close approximation of the temperature drop available for heat transference in a salt pan. The temperature of the vapor coming from the solution in any effect is the temperature at which water would boil under the pressure P_1 , existing in that body, and hence may be read from the curve, $G = 0$ (call this temperature t_1). Now if the mean hydrostatic head, expressed in mm. of mercury, is added to P_1 , the mean total pressure in the boiling liquid, P_2 , is obtained. On Curve V follow over the pressure P_2 until the particular concentration of salt existing in the pan is reached. The abscissa corresponding to this point

gives the mean temperature, t_2 , at which the solution boils. The difference between these two temperatures, $t_2 - t_1$, is temperature drop lost due to excess boiling point and hydrostatic head. The difference between

CURVE V. VAPOR PRESSURE AT VARIOUS TEMPERATURES OF VARIOUS NaCl SOLUTIONS

the temperature of the vapor coming from the previous effect and t_v is the temperature drop really available to cause transference of heat through the heating surface.

A complete table of values was read from Curve V, these data being given as Table V. This table gives the temperature at which the various solutions have a certain vapor pressure, as the data are most serviceable for evaporator design in this form. A "straight line" interpolation may be used between adjacent values to obtain intermediate values without increasing the error of the results. The plotting was carried out carefully, and to large scale, and it is felt that the values given in Table V are reliable to within certainly 0.2 deg. C. and 3 mm. pressure. All of the erratic results given in the regularly accepted standard tables have been eliminated, and the field from 50 deg. C. to the temperature at which the solutions will boil under one atmosphere pressure is given in much greater detail than hitherto. The values for saturated sodium chloride under diminished pressure are not found in any of the regular published tables. The results given are dependable to an accuracy which is more than sufficient for engineering design.

Diffusion of Solid Copper in Liquid Aluminum

Details of Experiments Where Copper Rods Were Dipped in Molten Aluminum Under Definite Conditions, and the Resulting Alloy Analyzed—Filtration Experiments Also Were Made in Various Ways, All Giving Nearly the Same Results

By ROBERT J. ANDERSON*

IN ORDER to obtain figures with regard to the rate of solution of solid copper in liquid aluminum, the following experimental method was employed: Copper cylinders were suspended in liquid aluminum, for various times and at different temperatures, and withdrawn after the desired elapsed time. The resultant alloy was then poured into a button, and analyzed for copper. Strictly speaking, the results of these experiments cannot give a truly quantitative measurement of anything other than the rate of alloying under definite conditions. However, the principles involved in the commercial manufacture of No. 12 alloy are identical with those in the present laboratory experiments, and consequently measurements such as these are of more direct practical worth to foundrymen than calorimetric diffusivity figures.

A foundryman is mainly interested in knowing how long it requires for the copper to go into solution under the conditions of plant practice, and the experiments carried out in this investigation give positive indications of the time required. As above stated, however, the results arrived at are complicated by factors other than time and temperature, because solution, diffusion and convection are all active, and the results give values for the combined effects of these factors. It is possible, however, to obtain useful information from such experiments, and the chemical analysis of the alloy buttons, as well as examinations of the copper cylinders, afford data as to the rate of alloying.

In foundry-melting practice there is always more or less stirring of the melts when heats are made, whereas in the present experiments there was practically no agitation. While it might have been possible to have employed a definite rate of agitation in the case of these experiments, say, by rotating the crucible at a constant rate, the net practical result of such a procedure would be simply to increase the rate of alloying.

METHOD OF EXPERIMENT AND MATERIALS

In the experiments with solid copper in liquid aluminum, two sizes of copper cylinders, $\frac{1}{2}$ in. in diameter and 4 in. long, and $\frac{3}{8}$ in. in diameter and 4 in. long, were used. (12.7 mm. and 7.9 mm. x 101.6 mm.) These were prepared by melting some copper punchings in a graphite crucible and pouring the liquid copper into cylindrical graphite molds. In experiments 1 to 14 inclusive, the larger cylinders were used, and in experiments 15 to 23 inclusive, the smaller ones were employed. In each experiment, 100 g. of aluminum was melted and brought to the desired temperature in a resistance furnace of the crucible type. When the aluminum was liquid and at the desired temperature,

a cylinder was suspended in the liquid aluminum by means of a graphite holder and a bronze clamp. In each experiment, the end of the cylinder was $\frac{1}{2}$ in. (6 mm.) from the bottom of the crucible, and the same surface area of copper was exposed to the same volume of aluminum. The aluminum was melted in a fireclay crucible of such a size that 100 g. of liquid aluminum filled the crucible about three-quarters full. After a cylinder had been suspended in the liquid aluminum for the desired time, it was withdrawn, and the resultant alloy in the crucible was poured into a button. In each test the alloy was thoroughly stirred before pouring, and the button was analyzed for copper. Temperatures were taken with a base-metal thermocouple. In all the experiments the temperatures given indicate the original temperature of the aluminum at the time of suspending the cold copper cylinder; on introducing the cylinder, a drop of 25 to 40 deg. C. occurred. This chilling was corrected by increasing the power input to the furnace, and thereafter the temperature of the liquid aluminum was maintained within ± 10 deg. C. of the desired.

TABLE I. DIFFUSION EXPERIMENTS WITH $\frac{1}{2}$ -IN. COPPER CYLINDERS IN LIQUID ALUMINUM

Experiment	Time, Min.	Temperature, Deg. C.	Per Cent Copper in Button
1	1.0	700	0.17
2	2.5	700	0.18
3	5.0	700	0.26
4	7.5	700	0.77
5	10.0	700	2.26
6	45.0	700	20.50
7	1.0	800	0.20
8	2.5	800	1.35
9	15.0	800	2.80
10	45.0	800	38.82
11	1.0	900	1.92
12	5.0	900	4.27
13	7.5	900	11.14
14	20.0	900	41.01

Where the cylinders were suspended for only one minute or two and one-half minutes, the drop was not recovered in these short periods of time. A summation of the results obtained with the $\frac{1}{2}$ -in. diameter cylinders is given in Table I.

Additional similar experiments were carried out, using $\frac{3}{8}$ -in. diameter cylinders. These cylinders were not suspended in the aluminum, however, but were simply so placed in the liquid metal that practically the same surface area of copper was exposed on each. The cylinders were withdrawn after the desired time; the resultant alloy was thoroughly stirred and poured into a button, and the button was analyzed for copper. In order to ascertain whether the surface condition of the copper influences the rate of solution, some of the small cylinders were freshly cleaned before immersion in the aluminum by boiling in 10.0 per cent sodium hydroxide, followed by washing in water. Those cylinders not cleaned had a slight oxide film on the surface. The results of experiments showed that the condition of the copper surface does not influence the rate of alloy-

*Published by permission of the Director, U. S. Bureau of Mines. Metallurgist, U. S. Bureau of Mines, Pittsburgh, Pa.

¹As pointed out in an article entitled "Some Theoretical Principles of Alloying," CHEM. & MET. ENG., vol. 23, No. 8, p. 317 (Aug. 25, 1920).

ing to any practical extent provided the surface is not badly oxidized. Hence, in foundry practice, it is not necessary to clean sheet copper or punchings in the manufacture of No. 12 alloy, provided the copper surface is in reasonably fair condition. Table II gives a summary of the experiments carried out with the small cylinders.

Additional experiments were made with thin copper punchings of circular form, punched from medium gage sheet. Such punchings go into solution in aluminum

TABLE II. DIFFUSION EXPERIMENTS WITH $\frac{1}{8}$ -IN. COPPER CYLINDERS IN LIQUID ALUMINUM

Experiment	Time, Min.	Temperature, Deg. C.	Per Cent. Copper	Condition of Copper Surface
15	2 0	700	0 60	Oxide film
16	5 0	700	6 63	Freshly cleaned
17	10 0	700	21 94	Freshly cleaned
18	1 0	800	0 16	Freshly cleaned
19	2 0	800	1 78	Oxide film
20	5 0	800	6 58	Freshly cleaned

22	2 5	900	7 75	Freshly cleaned
23	5 0	900	9 45	Freshly cleaned

rapidly even at low temperatures; one 30-g. punching was completely dissolved in five minutes at 700 deg. C. in 175 g. of aluminum with no agitation. The composition of the materials employed in the above experiments was as follows:

Material	Elements, per Cent			
Aluminum	Cu	Fe	Ni	Al*
Copper punchings	0 23	0 34	0 31	99 12
Large copper cylinders	99 89			
Small copper cylinders	99 94			
	99 86			

* Aluminum, by difference

DISCUSSION OF THE EXPERIMENTS

The results of the diffusion experiments, summarized in Tables I and II, show that copper readily alloys with aluminum when solid copper is placed in contact with liquid aluminum. The data given in these tables indicate tendencies rather than precise results, and show that copper goes into solution (alloys) with aluminum more rapidly with increasing temperatures, and that small pieces of copper dissolve more rapidly than large ones; in other words, the rate of diffusion is a function of the temperature, of the size and shape of the immersed copper, and of the ratio of the surface area of the solid copper exposed to the liquid aluminum. In preparing alloys of aluminum with copper on a commercial scale, for example No. 12 alloy, by this method, it is advisable to use light-gage punchings and clippings or light sheet scrap.

FILIIATION EXPERIMENTS

A few superposition ingots were made in order to show the filiation phenomenon for the aluminum-copper system and also to study this phenomenon in its relation to the subject in hand. These superposition ingots were made in a number of ways, but the results were more or less similar. In experiment 24, the copper was liquefied in a graphite crucible; interior dimensions $\frac{1}{2}$ -in. diameter and 4 in. deep. The crucible was about one-half full of copper. Small pieces of aluminum were then added as fast as they melted until the crucible was full of metal; the aluminum was dropped in, and some agitation resulted. When full of metal, the crucible was removed from the furnace and cooled in air. This experiment was repeated as experiment 25, but a crucible $\frac{1}{2}$ in. diameter and 4 in. deep was employed. In experiment 26, copper was melted in a $\frac{1}{2}$ -in. graphite

crucible in one furnace; aluminum was melted in a clay crucible in another furnace; when both metals were thoroughly liquid, the aluminum was poured onto the copper and the whole melt allowed to cool in air. In experiment 27, a cylinder of solid copper was placed in a graphite crucible 0.5 in. diameter and 4.0 in. deep; the cylinder was one which had previously been cast in a crucible of this size, and it fitted the crucible snugly. The cylinder was 2.0 in. long, and its upper surface was planed smooth and flat. A cylinder of aluminum of the same dimensions as the copper cylinder, and with the lower surface smooth, was placed on top of the copper cylinder so that the surfaces were in close contact. The crucible was then placed in a cold furnace, heated to 750 deg. C., held for two hours at that temperature, and cooled in air. The conditions for experiment 28 were the same as for experiment 27, but a crucible $\frac{3}{4}$ in. diameter and 4 in. deep was employed; the crucible containing the cylinders was then heated from room temperature to 800 deg. C., and then cooled with the furnace.

After cooling the ingots in experiments 24 to 28 inclusive, they were removed from the molds and examined microscopically. Because of the extreme brittleness of the rich alloy bands formed, the ingots readily broke in two at planes in the ingots corresponding to compositions roughly of 40 to 60 per cent copper. A number of photomicrographs of the typical structures found in the ingots were taken, and some of these are reproduced here.

FIGS. 1 TO 6.
Structure of alloy at distances of 1, 2, 3, 4, 5 and 6 cm., respectively, from the top of copper bar. Etched with NaOH. $\times 150$.

When solid copper is placed in contact with liquid aluminum at a temperature below the melting point of copper, alloying of the two metals takes place. The rate of alloying is dependent upon the temperature. When the metals are placed in contact in the order of their specific gravities (aluminum on top) the copper molecules appear to migrate upward. In experiment 26, where liquid aluminum was poured onto liquid copper, a section 6 cm. from the copper contained about 9 per cent aluminum, the copper content of the aluminum alloy on top being richest nearest the copper and leanest at the top of the ingot. This was shown by microscopic examination of the resultant ingot.

The result of superimposing liquid aluminum on solid copper may be shown by a description of the microscopic results of one of the above experiments. The ingot (made in experiment 26) was polished along one side and points 1, 2, 3, 4, 5 and 6 cm. from the copper in the direction of the upper end of the ingot were photographed. The amount of copper contained in the superposition alloy becomes progressively less as the distance from the copper increases. No aluminum could be detected in the lower extremity (copper end) of the ingot. Micrographs in Figs. 1 to 6 inclusive represent areas located at distances respectively 1, 2, 3, 4, 5 and 6 cm. from the copper in the direction of the upper end of the ingot. The structure shown in Fig. 1 is of practically eutectic composition (about 33 per cent copper), and the copper content of succes-

FIG. 7.

Assembled micrographs showing changes from bright copper, below, to a point 6 cm. above. Etched with $\text{NH}_4\text{OH} + \text{H}_2\text{O}_2$. $\times 85$.

sive areas becomes leaner and leaner until in Fig. 6 it is about 10 per cent copper.

The microstructure of the area extending from the copper in the direction of the point shown by Fig. 1 is illustrated by a series of micrographs taken at successive points along the section from the copper toward the 1-cm. point. Such a series of micrographs, joined together, are shown in Fig. 7. Considerable difficulty is experienced in securing good photomicrographs of a series of structures in one sample where the composition varies within wide limits, because of the unsuitability of any one etching reagent to a variety of structures. However, the series of micrographs given indicate the changing constitution of successive layers of a superposition ingot fairly well, showing the progressive leanness of successive layers in copper. While interesting, the study of alloys by preparing superposition ingots is not conducive to practical results, and fortunately there are better and more reliable methods.

SUMMARY

It has been shown by laboratory experiments that solid copper goes into solution in liquid aluminum fairly rapidly at relatively low temperatures, and that the rate of solubility and diffusion increases rapidly with rising temperatures. Thus, small pieces of copper go into solution in aluminum fairly rapidly at 700 deg. C., but very rapidly at 900 deg. C. Hence, the commercial method for the manufacture of No. 12 alloy by adding copper directly to aluminum is a rational procedure from the metallurgical standpoint. That it may not be the best method or the one most easily adapted to foundry practice will be discussed later.

Market for American Dyes in Foochow

Evidence of a potential market for American dyes in Foochow is given in a recent report from Consul Ernest B. Price. German dyes, which practically held a monopoly of the market before the war, have been displaced largely by imitation dyes, the labels and packages not showing country of origin. In 1918 the total imports of aniline dyes into Foochow were \$10,626; in 1919, \$16,064; and in the first quarter of 1920, \$11,296. Imports of artificial indigo for 1919 were \$20,854, and of vermillion, \$15,718. Vermillion imports for the first quarter of 1920 are given as about \$4,000. Quite a percentage of the dyes imported is used in the dyeing of paper, scarlet being the color most in demand. Aniline dyes in rose azure, magenta, fast red, indigo blue, orange, green, violet and black are used for dyeing cotton cloth and silk cords.

Lubricating Oil From Asphalt Deposits in Palestine and Syria

A recent report from Consul General Ravndal at Constantinople is to the effect that in order to meet the pressing demand for lubricating oil the directors of the Syrian and Hedjaz railways in 1916 adopted the suggestion of a German geologist to distill the bituminous limestones (asphalt) which are found abundantly in Syria and Palestine. This was done by setting up a special oven and distilling apparatus at a cost of 3.45 piasters per kilo of oil. Between Aleppo and the Red Sea thirty distinct deposits of bituminous schists are known, chief of which are those of Hasbaya, Hadete, Dumar, Mekarine and Nebi Moussa.

Present Status of the Nebraska Potash Industry

Observations on General Conditions and Probable Future of the Industry—Historical Note on the Discovery of Potash in the Nebraska Lakes—Need of Improved Technology in Methods of Operation—Current Fuel and Labor Costs

EDITORIAL CORRESPONDENCE •

IT IS conservatively estimated that more than \$12,000,000 has been expended in establishing the Nebraska potash industry in the western part of that state, where alkaline lake waters are evaporated for the recovery of mixed salts containing potash in the form of sulphate and carbonate. In spite of the fact that the industry was started during the war and enjoyed high prices for some of its products, the return on the investment has not been adequate. The Nebraska lakes have been our best potash resource for several years past, but for one reason or another the companies as a whole have not prospered.

Considering the attraction which the business held during the early years of the war, when potash could be quickly recovered and sold at high prices, it is not surprising that one or two "wildcats" were promoted and foisted on a gullible public. For the most part, however, the companies which were formed had a legitimate reason for existence and have conducted their operations honestly.

The industry has had its ups and downs, due to various causes, the period of greatest prosperity being due to the shortage of potash caused by the war and the period of greatest depression being due to the change in conditions following the armistice. It seems likely that during the war the Nebraska potash producers became overconfident and felt that their product was so essential that the fertilizer companies or other consumers must take it at any price. It is equally evident that when the armistice was declared the fertilizer companies which had been buying the Nebraska product believed that it would be but a short time before they might again secure foreign potash, and consequently assumed an indifferent attitude toward domestic producers. In fact the fertilizer companies refused to buy and the lack of harmonious co-operation resulted in closing the potash plants in February, 1919, for lack of a market. At that time the producers had on hand about 70,000 tons of salt, containing the equivalent of 25 per cent K_2O . This they were obliged to carry in storage at a considerable expense, refusing to sell at \$1.50 per unit material which had cost them from \$1.80 to \$3 per unit to produce. This conflict of interest between producer and consumer resulted in a cessation of operations until the fall of 1919. In the meantime the accumulation of 70,000 tons was sold gradually at prices varying from \$1.75 to \$2.25 per unit K_2O .

CONTRACTS FOR 1920 PRODUCTION

Importation from foreign sources during 1919 failed to meet the expectations or needs of the fertilizer companies and a market was again afforded for the domestic product. This resulted in placing the Nebraska potash plants in operation about September, 1919. In

the meantime the producers had endeavored without success to obtain tariff protection from Congress, and resumed operations in the hope of making a favorable contract with fertilizer companies. This was the subject of negotiations last spring and resulted in an agreement for the disposal of 50,000 tons of mixed salt averaging about 25 per cent K_2O , at \$2 per unit. This is practically the production of the district for the summer season and will insure operation at least until fall. If it then appears that foreign potash will still not be sufficient for domestic consumption, a further contract may be made for the winter output. The fertilizer mixing season extends from September to April, and with the close of each season the fertilizer companies have shown a disposition to wait for foreign potash at a low price rather than contract for the domestic product. This policy works very much to the disadvantage of the producers, however, inasmuch as their best season for production is the summer time, and they should begin operations with assurance that they can sell their products, just about the time the fertilizer companies are finishing their mixing and selling campaign. Thus the producer finds himself in a state of uncertainty as to his market just at the time when he should be most actively engaged in production.

PRICES OF POTASH

The price at which the current season's output is contracted for—viz., \$2 per unit—is regarded as being about the minimum which ordinarily the companies can accept and make a profit. In fact it is claimed that the price entails a loss in every plant in the district this year. The general sentiment in the district is that the companies should receive about \$2.50 per unit in order to return their investment and realize a profit. Some companies even figure as high as \$3, while a few are confident that improvement in the technology will permit well designed and operated plants to run possibly at \$2 per unit, or less. Certainly a lower cost can be obtained during the summer season when solar evaporation is a great factor in production.

IMPORTANCE OF NEBRASKA POTASH

According to "Mineral Industry," the domestic production of potash in 1918 was almost double that in 1917, and Nebraska brines supplied 55 per cent of the total. At present the district is capable of producing in the summer season from 500 to 600 tons of mixed salt per day, averaging 24 per cent K_2O . During the winter the output is reduced to 300 tons of mixed salt per day. Eight companies are now actively engaged in production, their plants having capacities varying from 150 tons of mixed salt per day down to 25 tons per day. The following companies have survived the difficult months following the armistice and are the

active producers: The Potash Reduction Co., Hoffland; American Potash Co., Western Potash Co., Union Potash Co., Alliance Potash Co., and Nebraska Potash Works, Antioch; Hord Potash Co. and Standard Potash Co., Lakeside.

HISTORICAL NOTE

In view of the important position which the Nebraska potash industry evidently has attained, more than ordinary interest attaches to its early history. The notes here recorded are from personal interviews with Wilson H. Low, late head chemist for the Cudahy Packing Co., Omaha, Neb., and Carl L. Modesitt, of the Potash Reduction Co.

About 1906 a Mr. McCarthy of Alliance, Neb., offered to sell to the Cudahy Packing Co. about thirty tons of alkali which he had scraped from the dried surface of one of the lake beds in the western part of the state. The Cudahy company purchased the lot and used it without further purification for making caustic soda solution. In fact soda was the only salt of interest to either Mr. McCarthy or the Cudahy company, and no one had suggested that potash might be present. The incident resulted in a trip by Mr. Low to examine some of the lakes, and subsequent trips were made in two successive seasons. Conditions were found as represented by Mr. McCarthy and resulted in a careful survey of Jesse Lake, its area, probable depth of mud and amount of alkali on the surface and in the mud. In September, 1908, Mr. Low reported to E. A. Cudahy that on the occasion of his last visit Jesse Lake was largely dry and covered by a thick deposit of crystallized alkaline salt over an area of several hundred acres. A 50-lb. sample of mud was taken from the lake bed and a sample of the salt deposit was scraped from the surface of 25 sq.ft. A laboratory examination of these materials showed that the mud contained about 3 lb. of dry sodium carbonate or its equivalent per cu.ft. The crystal deposit on the surface contained sodium carbonate or its equivalent to the extent of about 10 lb. per 25 sq.ft. Calculated in quantities per acre, these figures showed sixty-five tons of sodium carbonate or its equivalent in the mud and nine tons on the surface, or a total of seventy-four tons per acre in the top foot. As a result of the analyses made by him on this occasion, Mr. Low discovered that the alkali contained appreciable quantities of potash, which made the deposits more valuable than if they contained soda only. Soda ash was then worth about \$18 per ton in Omaha, while potassium sulphate or chloride was worth over \$100 per ton for mixed fertilizer or other purposes. Accordingly he recommended that Cudahy Packing Co. acquire control of some of these lakes as a source of potash for fertilizer and other purposes, but, owing to other projects which this company had under way at that time, no steps were taken to get hold of the lakes.

The record of Mr. Low's investigation and analyses was available to anyone who was interested, and when the Cudahy company showed no active interest the matter was taken up by John H. Show, head assistant in Mr. Low's laboratory. Mr. Show interested some associates, Carl L. Modesitt, C. C. Denny and V. I. Jeep, who decided to treat the lake waters for the recovery of alkali.

In March, 1910, Mr. Modesitt conducted a rough survey of about twenty ponds and lakes, and analysis

was made of about seventy samples of water, mud and crystal. In February, 1912, Mr. Modesitt erected an evaporating tower and made about one ton of crystallized salt which he submitted to different fertilizer companies. A further survey of the alkali lake region was made during 1912-13, and in 1913-14 the refining problems were studied with a view to separating the potash and soda for the purpose of reducing freight cost and securing a higher price for the refined products. By April, 1915, Mr. Show and his associates, who had organized the Potash Products Co., had spent about \$17,000. They then got sufficient financial backing to start a plant on a commercial scale, and they assembled and erected a 125-hp. boiler and two evaporating pans with steam coils. Water was pumped from Jesse Lake through a 2½-mile pipe line to the plant. Operations began June 10, 1915, and the first carload of mixed salt was shipped eight days later. The Potash Reduction Co. succeeded the Potash Products Co. in August, 1917, and has continued to be one of the prominent factors in Nebraska potash production.

WAR INSURED SUCCESS OF VENTURE

The financial success of this first venture was greatly enhanced by war conditions, which placed a high premium on potash, and the Potash Products Co. sold its early production for as much as \$5 per unit K₂O. It was inevitable that others should be attracted to the industry, and as a consequence the Nebraska Potash Co., the American Potash Co., the Hord Potash Co., the National Potash Co., the Western Potash Co., the Alliance Potash Co., the Standard Potash Co. and others came into existence in 1916-17. In addition to these larger concerns, which built the most important plants, there were between twenty-five and thirty companies of minor importance, about half of which produced some potash.

It is evident from this brief sketch that the credit for the original discovery of potash on which the industry subsequently was founded belongs to Mr. Low, while to Mr. Show and his associates is due the credit for the first commercial development.

METHODS OF OPERATION

General conditions in the district and a description of the methods of operation have already been published in *CHEMICAL & METALLURGICAL ENGINEERING*¹ and there have been few changes of importance since that article was published, due largely to the fact that the plants were closed for so long a time. Operations consist in pumping water from the surrounding lakes, often as far as twenty miles; evaporating in multiple-effect evaporators to about 33 per cent solids, and finally drying in rotary kilns which discharge the dry-mixed soda and potash salts. It is considered unprofitable to pump and evaporate water of less than 4 per cent total solids, of which perhaps half is potash salts. During the summer season solar evaporation is a great aid to production and it is customary to "farm" the lakes by pumping from one to another. If water from one lake is pumped onto the dry bed of another, and taken out again at the opposite side, solar evaporation will have concentrated the water to several times its original salt content. Mr. Low has made some calculations of the value of solar evaporation, based on the fact

¹"The Nebraska Potash Industry," by Ernest E. Thum, vol. 17, No. 12, Dec. 15, 1917.

that in hot weather in western Nebraska evaporation will amount to from $\frac{1}{2}$ in. to $\frac{3}{4}$ in. per day. At the lower figure the evaporation from an acre of water would amount to twenty-five tons per day, so that from a 100-acre lake it would be possible to evaporate 2,500 tons of water per day, due to solar effect alone. By suitably handling the lower-grade lake water it is possible to deliver to the plant a brine of high specific gravity practically ready for final evaporation.

Wooden pipe lines have been largely substituted for iron for the transportation of water from lakes to plant. Some companies have as high as 100 miles of pipe, which involves a large expenditure. It is necessary to lay the pipe below the surface, and 8-in. pipe costs about \$5,000 per mile laid and 6-in. pipe about \$3,500 per mile.

EVAPORATOR PRACTICE

Evaporator practice has been much improved since the early days of the district and the equipment of the later plants is superior to that of those first built. The kilns are oil fired, but experiments have been made with powdered coal which indicate that economies can be effected by the latter fuel. According to the best practice in the district it now requires about 55 gal. of oil to produce one ton of dry salt when the kiln feed contains about 33 per cent solids. Preliminary experiments by the Hord Potash Co. with powdered coal indicated that the same work could be done with 1,000 lb. of coal; and since oil costs 8c. per gal. and coal over \$4 per ton at the plant, there would be a decided advantage in the use of coal if it could be satisfactorily applied without requiring too much plant equipment. Recent information is to the effect that the Hord company has adopted and installed Aëro size B and D pulverizers and that a saving is being made of \$1.50 and \$2 per ton of dried salt.

The cost of all operation has increased greatly since the plants were first built and started. In the beginning it was possible to get coal from Sheridan, Wyo., at 35c. per ton f.o.b. mines and a freight charge of \$2 per ton. In April, 1920, the same coal was costing \$1.70, and in August, 1920, \$1.95, f.o.b. mines, with a freight charge of \$2.30 per ton. Labor originally cost the companies from 15c. to 20c. per hour with meals and lodging, the latter amounting to about \$1 per day. In April, 1920, the charges were from 50c. to \$1 per hour with an average of 62½c., the men paying for their bed and board. Freight on potash from the district to southern points was \$10.80 per ton last spring, but of course this will be notably advanced if it has not already been advanced.

IMPROVED TECHNOLOGY NECESSARY

There is a tendency throughout the district to get more and better technical advice than was customary in the early history of the region. This may be regarded as one of the most hopeful signs for the future of the industry, inasmuch as it is quite evident that improved technology must be relied upon to reduce the cost of production and enable the companies to meet foreign competition when it becomes active.

In addition to obvious economies in boiler and evaporator practice, probably one of the best lines of improvement will be in the separation of sodium from potassium salt. At the present time the product of the district contains about as much soda as potash. The former is without value to the fertilizer companies

and serves merely to dilute the potash and increase the expense for freight. By making a separation of the salts it would be possible to produce several materials of value instead of one. A number of processes are now under experiment and it would seem as though the present season should witness the development of methods that can be put into active use next year. One of the processes involves causticizing the concentrated brine with CaO, the subsequent conversion of caustic potash to sulphate by the addition of sodium sulphate, with final evaporation and salting out of the potassium sulphate, the caustic soda remaining. Other processes under experimentation involve fractional crystallization of the different salts and production of soda ash.

A radical departure from general practice in the district was made last spring by the Merriman Potash Products Co. in an effort to make a product approximating a mixed fertilizer. It was claimed that by treating phosphate rock with brine in the drying kilns, a conversion takes place which renders the phosphoric acid soluble and therefore available. The reaction is not clear, although it is known that the so-called calcined phosphate produced by mixing phosphate rock, sodium sulphate and carbon, and subjecting the mixture to the heat, will render phosphoric acid available. It is doubtful if enough work has been done to determine the value of this procedure, but if it meets the claims of the company it is possible to secure plenty of phosphate rock from Idaho and Montana, treat it in transit and forward the product to the fertilizer companies. The company has since gone into the hands of a receiver and none of the other plants in the district is attempting to make this kind of product. It is doubtful, therefore, if there will be any further developments in the near future.

FUTURE OF THE INDUSTRY

The future of the Nebraska potash industry cannot be determined with any degree of finality at this time, although there is ample reason to believe that the industry can exist profitably for a long time. There will be the inevitable dropping out of the smaller and weaker concerns, and the strengthening of the larger companies by better technology and business methods. A greater study of the lake areas and of methods of concentrating the brine will undoubtedly reveal tremendous resources. Solar evaporation and systematic "farming" of the lake waters will also play a large part, and in fact the industry may develop into a seasonal one. Sooner or later the industry must meet foreign competition, because potash from abroad is being imported in increasingly large quantities, and will continue to come in the future. There is reason to believe, however, that the domestic industry will be able to meet this competition and continue to operate at a profit. In this connection it is quite evident that harmonious relations between the producers and the large consumers will do much toward stabilizing the industry.

Profits of Swedish Government Water-Power Administration

The Swedish Government operation of water-power sites reports a gross income for 1919 amounting to 13,897,649 crowns and expenditures of 7,622,750 crowns. Nearly all the water-power plants now in operation show a profit to the government, and most of the expenditures are for additions and new construction work on power sites that have not yet been completed.

Properties and Industrial Uses of Cellulose Acetate*

A Summarized Outline of the Properties of the Normal Acetate and of Its Uses in the Manufacture Especially of Dope, Celluloid, Impermeable Fabrics, Artificial Leather, Artificial Silk and Electric Insulation

BY MAURICE DESCHIENS

THE normal cellulose acetate or tri-acetate, more or less mixed with di-acetate, appears in the form of a coarse powder or as rough amorphous filaments whose structure varies with the cellulose used, the method of preparation, the ripening and the conditions of precipitation. Thus cellulose acetates prepared from wood cellulose are in general coarser, rougher and more viscous in acetone solution than those obtained from cotton.

The average density of cellulose tri-acetate is 1.2. When distilled or volatilized it is decomposed at about 210 deg. C. The higher acetates, unless perfectly washed and stabilized, have a tendency to decompose into simpler esters with the formation of free acetic acid, a decrease in solubility and increase in viscosity. The tri-acetate is less flammable and less combustible than the nitrocellulose.

SOLUBILITY

The commercial cellulose tri-acetate is completely insoluble in water, pure methanol, ethyl alcohol, butyl alcohol, ether, benzene, methylacetone, pure ethyl acetate, amyl acetate, tetrachlorethane, butyl formate, carbon tetrachloride, toluene and triphenyl phosphate. It has the property of swelling in contact with water, alcohols, benzene, butyl formate and methylethylketone. This property of swelling is the more marked when in contact with water at ordinary temperature and with a mixture of equal parts of methanol and ethyl alcohol and benzene at about the boiling temperature. When thus swollen the acetate is much more sensitive to the action of certain solvents such as acetic acid, is completely saponified at ordinary temperature in a few hours by N. 2 potash, and absorbs with great rapidity and in proportion with its degree of swelling dyes such as methylene blue. This last property is used industrially.

The cellulose tri-acetate is soluble in the cold in a great number of organic solvents such as acetaldehyde, acetal, acetone, formic acid, acetic acid, methyl formate, ethyl formate, methyl acetate, aniline, phenols, cresols, benzyl and oxybenzyl alcohols, pyridine, quinoline, triacetone, cyclohexanone, amyl and butyl tartrates and citrates, benzyl aldehyde, acetylacetic ester, ethyl oxalate, ethyl lactate, acid oxalates and lactates, mesityl oxide, glycol di-acetone, carvacrol, carvol, eugenol, isoeugenol, safrol, isosafrol, phthalic esters, guaiacol, creosote, acetamide, anethol and terpinol. It is more soluble in warm eugenol, furfural, triacetone and chloroform. Its solubility at boiling temperature in a mixture of equal parts of methanol or ethyl alcohol and benzene is used in the manufacture of cellulose acetate in sheets and in plastic masses.

A fact which deserves special attention is that substances which may be called auxiliary solvents, when

alone, do not dissolve cellulose acetate, but when these substances are mixed with non-solvents of acetates, such as ethyl alcohol, methanol and benzene, which may be called diluents, the mixture becomes a cellulose acetate solvent even with small quantities of the diluent. This is the case with methylethylketone, ethyl acetate, tetrachlorethane, cold chloroform and butyl formate. For example, when ethyl acetate, a non-solvent of cellulose acetate, is mixed with 4 to 5 per cent of ethyl alcohol the mixture dissolves the cellulose acetate in the proportion of 1 g. acetate per 9 g. of the mixture.

INDUSTRIAL USES

Aeronautics Industry.—Prior to the development of aeronautics, cellulose acetate dope has been used to coat balloon fabrics, making them impermeable to gases. A typical composition was:

	Grams
Cellulose acetate	15
Rubber	2
Tetrachlorethane	100

The considerable progress realized during the last few years in heavier-than-air aeronautics, with the resulting need to impart to the planes certain qualities, contributed greatly to the development of the industry of dopes having cellulose acetate as base.

These dopes are obtained by dissolving cellulose tri-acetate in a mixture of more or less volatile solvents. This mixture consists of light solvents (acetone, methylacetate, ethyl formate) having a boiling point as low as 50 to 60 deg. C., to which is added diluents such as ethyl alcohol or methanol, benzene, with a boiling point of 80 to 115 deg. C., and heavy gloss-retaining solvents such as benzyl alcohol and phenol, which vaporize very slowly and only partly, their boiling point being 130 to 200 deg. C.

By evaporating the solvents there is left an elastic film of variable thickness which has to have the following qualities: Homogeneity, transparency, retractibility at the time of its formation, elasticity, suppleness, tenacity, impermeability to water, castor oil and volatile oil, and ability to increase the tension and tearing resistance of the coated fabrics and make the surface of the coated fabrics polished in contact with the air so as to reduce the coefficient of friction of the air on the planes, and thus insure a greater velocity of the air-planes.

STANDARD DOPE FORMULAS

During the war extensive tests were carried out by the Allies on a formula for a dope which resulted in the adoption of the following standards which have given excellent results:

	80	80
Cellulose acetate	860	890 880
Diluents and light solvents	30	40
Heavy solvents (benzyl alcohol or phenol)	(summer)	(winter)

*Abstracted and translated from *Chimie et Industrie*, May, 1920, pp. 591-607; see *CHEM. & MET. ENG.*, vol. 23, No. 11, p. 533.

or:

Cellulose acetate.....	80
Diluents and light solvents.....	800
Furfural.....	60

The relative quantities of diluents and light solvents, the products being pure, are:

Acetone (light solvent).....	410
Benzene } diluents {.....	250
Alcohol }.....	230-220

or:

Methyl acetate (light solvent).....	513
Benzene } diluents {.....	250
Alcohol }.....	117-127

or:

Ethyl formate (light solvent).....	455
Benzene } diluents {.....	250
Alcohol }.....	125-175

The light solvents may be replaced in the above formulas in the proportion of 3:8 by the following light auxiliary solvents: ethyl acetate, methylethylketone, and butyl formate.

The dope is applied in three layers on the linen fabrics after these are already fixed on the wings of the plane. The total thickness of these layers is such as to represent 70 to 80 g. per sq.m.

TESTS OF THE COATED LINEN FABRICS

Tensile Strength.—The tensile strength of the linen is determined by an apparatus called aërotensiometer, represented in Fig. 1, which measures the deflection produced in the stretched non-coated or coated fabrics by the application in the center of a known weight. The apparatus consists of the following essential parts: A metallic disk *B* having a rim *R* which is applied to the fabric to be tested. The plate *P* presses on the fabrics under the action of the spring *S*. The deflection is indicated on *D* to the tenth of a millimeter.

FIG. 1. AËROTENSIOMETER

Tests made with this apparatus gave the following deflection values for non-coated and coated fabrics:

	Deflection Mm.
Stretched non-coated linen fabrics.....	13.7
Same quality of linen stretched and coated with:	
1. Layer of standard acetone and benzyl alcohol dope, the thickness of the film being 36 g. per sq.m.....	6.0
2. Layer of same dope, thickness of film being 56 g. per sq.m.....	4.9
3. Layers of same dope, thickness of film being 74 g. per sq.m.....	4.3

The minimum deflection is obtained when the thickness of the film corresponds to 80 to 85 g. per sq.m.

Impermeability.—This is measured by noting the number of days required for water to permeate through the film.

Resistance to Rupture.—When tested with the warp or with the woof the non-coated linen fabric presents a resistance to rupture of 1,500 kg. per lineal meter; when coated with three layers of dope, the thickness of the film corresponding to 70 to 80 g. per sq.m., the resistance to rupture is increased from 25 to 50 per cent. The average resistance to rupture is 1,812 kg. per lineal meter with the warp and 2,175 kg. per lineal meter with the woof.

According to A. de Guiche, for an airplane traveling at a speed of 250 km. per hour (150 miles per hour) the pressure exerted on the plane is 180 kg. per sq.m., which corresponds to a tension of only 150 kg. per lineal meter. This figure indicates that coated fabrics present a high safety coefficient.

INDUSTRY OF CELLULOID, PLASTICS, FILMS

Cellulose acetate, being less flammable than nitrocellulose, is used now extensively in the preparation of celluloid.

A typical example of the composition of such a celluloid is that of Ernst Zühl (American patent 729,990, 1903): 70 parts nitrocellulose, 30 parts cellulose acetate, 50 parts camphor.

There is now a great variety of formulas used for the manufacture of non-flammable celluloids. They may or may not contain camphor. They also may contain cellulose esters, various solvents, oils, casein, mineral pigments, etc.

The manufacture of acetic cellulosic plastics may be considered as a branch of the celluloid industry. The principle on which is based the production of these plastics is that the cellulose tri-acetate, which is soluble in acetone and totally insoluble in alcohol and benzene or their mixture, can be dissolved by a mixture of equal parts of acetone with alcohol or benzene at about boiling point, from which it is re-precipitated as a gelatinous mass when the temperature is lowered.

The entire process of the manufacture of cellulose acetate plastics consists first in the realization of the above-described solution and precipitation. The liquid is now decanted, camphor or another plasticizing mass is added to the gelatinous precipitate and heated to 50 to 60 deg. C. until a homogeneous mass which can be molded, cut and pressed is obtained. This mass may also be squeezed through dies for making bars, threads, etc. (Société Industrielle de Celluloid-Sicoid, etc.)

These plastics are used for the manufacture of imitation amber, scales, combs, artificial flowers, etc.

Cellulose acetate sheets used for guards, transparent plates for automobiles and airplanes, windows, etc., are manufactured by mixing cellulose acetate pastes with plasticizing products and with other substances as desired. These mixtures are then rolled, compressed in block presses, cut with special cutters, some of which are automatic, and straightened when hot by appropriate presses.

Reinforced acetate sheets are manufactured by the same process, but with the use of special mechanical apparatus for the incorporation of metallic reinforcing.

The plastic plates resist well the action of rain, snow and other atmospheric agents, when they contain a sufficient proportion of plasticizing products and heavy solvents.

The principle of the manufacture of photographic plates and sheets is the same as that for plastic sheets, but special care has to be exercised in the mechanical regulation of the thickness of films, the plasticizing material used and the application of a sensitized gelatine coating.

IMPERMEABLE FABRICS—WASHABLE LINEN

Impermeable fabrics may be obtained by impregnating the fibers with cellulose acetate solutions. Similarly washable linen is obtained either by treating the linen with a 20 per cent solution of cellulose acetate in an appropriate solvent and applying to the treated linen a nitrocellulose varnish, or by the application of a basic aluminum acetate, drying and coating with cellulose acetate.

ARTIFICIAL LEATHER—PATENT LEATHER

Artificial leather is manufactured from the cellulose acetate of old films. Cloth imitating the grain of leather is coated with a mixture of cellulose acetate, appropriate solvents such as chinawood oil, linseed oil, castor oil, pigments, fillers such as chalk, kaolin, cork and other substances such as gutta percha, oils and glycerine.

Patent leather is obtained by coating the leather with any of the above mixtures or with a mixture having a nitrocellulose base. (U. S. patents 627,493—1899; 848,357—1907, etc.)

ARTIFICIAL SILK

A great number of patents have been granted for the manufacture of artificial textiles having cellulose acetate as base, but practically all of these patents follow the same principle, namely:

Cellulose acetate thread is obtained by passing its solution through orifices into another solution which precipitates the acetate. The thread is used for artificial textiles, filaments for incandescent lamps, gas mantles (Welsbach system), artificial horsehair, artificial silk, etc.

Of these the most important is the manufacture of artificial silk. The production of artificial silk with a cellulose acetate base is progressing rapidly, especially

in the United States, Great Britain and Belgium. The consumption, which in 1914 was 11,000,000 kg., is now greatly increased.

There are two distinct methods of manufacture—namely, the wet process and the dry process. [This is also the case for the manufacture of artificial silk with nitrocellulose base (Chardonnet) or by dissolving cellulose and hydrocellulose in ammoniacal copper oxide solutions (Parisian silks, Pauly-Glauzstoff) or with xanthate silk (viscose).]

Wet Process.—The cellulose acetate in the form of a very viscous paste with appropriate solvents and plasticizing agents which makes it supple is forced through capillary orifices of glass, crystal, or even platinum. The thread is led into a bath containing a solution which precipitates the cellulose acetate and eliminates almost all of the solvents. A number of these fine threads are twisted together by means of spools rotating at very high speed; this multiple thread constitutes the artificial silk which can be woven.

The volatile solvents used in this method are recovered, thus lowering the cost price.

Dry Method.—A viscous solution of cellulose acetate is passed in a steady stream through fine orifices into an airtight chamber heated to about the boiling temperature of the solvents used. The semi-solid thread is wound around rapidly rotating drums placed in the interior of the chamber. The solvents are gradually eliminated and the threads solidify. Here also a number of these fine threads are twisted into one thread which constitutes the artificial silk.

The recovery of the solvent is very easy in this case. It is sufficient to recover it from the hot air which is saturated with solvent vapors by any one of the known modern methods.

The artificial silk with a cellulose acetate base is non-flammable, very brilliant, very supple, its specific resistance to moisture is greater than that of any other kind of artificial silk, it washes very well without deterioration and constitutes the best washable silk. It is easily distinguished from the other kinds of artificial silks by its density, which is 1.250, solubility in acetic acid, insolubility in a cupro-ammoniacal solution and by its becoming yellow when treated with iodine and sulphuric acid.

ARTIFICIAL SPONGES

The product obtained by incorporating fibrous materials and sodium chloride or sugar with a cellulose acetate paste and washing with water constitutes artificial sponges. (British patent 21,524—1914.)

ELECTRIC INSULATORS

The use of cellulose acetate as insulator for electric wires and cables becomes more and more generalized, especially in America and Great Britain. The acetate is used in the form of threads which are wound around the cables or in the form of a solution in a volatile solvent which when evaporated leaves an insulating coating of cellulose acetate.

MISCELLANEOUS USES

Cellulose acetate is also used in the composition of certain explosives, in the manufacture of phonograph records, bayko thread, capsules, lacquered paintings, certain adhesives, and special cements, artificial pearls, and as a gelatinizer associated with gelatine for the manufacture of solidified alcohol.

FIG. 2. CELLULOID CUTTING MACHINE

The Value of Patents

BY CHESLA C. SHERLOCK

IT IS very seldom, even in this country, where thousands of patents are granted annually, that we pause to consider just what a patent is worth. Many persons are discouraged, when they come to seek a patent, because they think it is too much of an effort, too hard to obtain to be worth while for a trivial invention or improvement.

A patent is worth all the effort necessary to obtain it. The very fact that it is hard to obtain the grant, that it is given only after the most painstaking search of the records of the Patent Office, should in itself signify that it is something more than a "mere scrap of paper."

Just what does a patent grant to the patentee? The rights and privileges which he obtains have been reduced to a few simple statements gleaned from the statutes and the opinions of the courts.

1. Exclusive right to make the invention for seventeen years.
2. Exclusive right to use the invention for seventeen years.
3. Exclusive right to sell the invention for seventeen years.

This exclusive right to the manufacture, use and sale of the patented article is termed three rights of monopoly, and they apply to the entire territorial jurisdiction of the United States. They survive to the heirs and assigns of the patentee.

As expressive of these rights of monopoly in the patented article, the courts have held that the following additional rights repose in the patentee:

1. To exclude all others from making, using or selling same.
2. Right to an injunction against further infringement and to recover all profit lost by wrongful infringement of patentee's rights.
3. Right to restrict making, using or selling in any manner desired.

In order to comprehend the vast rights which a patent confers upon an inventor, one has only to recall the fact that all monopoly is ordinarily odious to the law and that the law seeks at every turn possible to destroy it.

PATENTEE'S MONOPOLY PROTECTED BY LAW

But in the case of a patent, we find the law not only sanctioning a monopoly but in fact creating that monopoly and conferring it upon one citizen or other person to the exclusion of all others. But that is not all. The fact is that the law not only creates the monopoly, but is bound to protect the patentee in that monopoly during the life of the patent. Such, then, is only one of the rare privileges which accrue to a patentee under our patent laws.

Any effort to restrict or control sale prices of a manufactured product under our laws has met with instant prosecution on the part of the Government. The Government has ever declared itself to be in direct conflict with all who seek in any way to limit the price at which their products may sell.

Is this true in the case of patented articles? Strange to say, most strange indeed it will appear to business men, the courts have not only kept their hands off, but the prosecuting branch of the Government has also remained passive, for it was long ago determined that patent owners have the right to restrict selling prices.

The Gillette Safety Razor case or the Victor Talking Machine agreements are instances in point with which most of us are familiar. The patentee in these cases has not only fixed the resale price of his product, but he has further specified the uses to which his product may be placed, and if the purchaser fails to use the products as specified, he becomes an infringer under the patent laws and may be sued for damages by the patentee. In the case of the Gillette razor the mere resharpening of the blades is an infringement, or in the case of the Victrola, to play records of another make upon the Victrola amounts to infringement.

LIMITATIONS TO PATENT MONOPOLY

It is, however, coming to be recognized that some limitation or curb must be placed upon the right to control resale prices, else the whole structure of our anti-trust laws would, in some instances, come tumbling down. In the famous O'Donnell case, it was held that the resale price cannot be controlled by the patentee or owner where the patented article passes through another's hands. In this case it was said that the retailers can, in that event, no longer be held as infringers if they cut prices. But if the manufacturer or owner of the patent uses his own selling organization and eliminates all middlemen, selling direct to the dealers, he can still regulate his prices to retailers, and this is just the method that the Victor people and others use to control the resale price of their product.

One court has said: "Within his domain the patentee is czar. The people must take the invention on the terms he dictates or let it alone for seventeen years. This is a necessity from the nature of the grant. Cries of restraint of trade and of the impairment of the freedom of sales are unavailing, because for the promotion of the useful arts the Constitution and the statutes authorize this very monopoly."

PATENTS ARE PERSONAL PROPERTY OF PATENTEES

It should also be kept in mind that a patent is personal property and cannot be taken away except by due process of law, which includes only constitutional decrees of competent courts. It does not include legislative acts either of Congress or of the Legislature. It cannot be seized under a writ or other execution of the common law, but it may be attached by a creditor's bill in equity, in default of the payment of a judgment.

The law provides that all patented articles must be plainly marked so that all may know the facts. But if one marks an article so as to give an impression that it is patented when, as a matter of fact, such is not the case, it is a criminal offense, punishable by a \$100 fine, one-half of which goes to the person bringing the action.

Patents are not merely a trivial right which one may obtain at a great deal of effort. They are among the most valuable property rights which an individual can possess. The law has done everything possible, even to overturning well-established rules of public policy, to make the patents as valuable and as effective as possible.

No business right enjoyed can be greater than a monopoly. A patent is not only a monopoly in one particular, but in several. It goes without saying that it is worth while for anyone to obtain a patent on his inventions or improvements, for the law intends that he should have it and the fruits thereof. It is only a partial recompense for the service rendered all the people in the improvements made as a result of the patentee's skill, genius or craftsmanship.

Synopsis of Recent Chemical & Metallurgical Literature

Humic Acids.—In the July 24, 1920, issue of *Chemiker Zeitung*, Dr. FRIEDRICH FUCHS describe the result of his work on the humic acid obtained from peat by the action of alkalis. He found that humic acid is a true acid and not a colloidal substance. It gives simple (not double) salts with bases following the stoichiometric laws. The analysis of the free acid gives C = 57.4 and H = 4.6 per cent, with little N and less than 1 per cent S. Humic acid from non-purified peat contains greater amounts of sulphur. Humic acid treated with organic or inorganic acids always gives a precipitate. Alkaline humates are only partly precipitated by a solution of sodium chloride but are completely precipitated by hydrochloric acid. The latter precipitate when dried gives a brown powder easily soluble in soda, whereas the former dried precipitate is darker and insoluble or only slightly soluble in soda. Humic acid treated with Na_2SO_3 gives a soluble sulphite which reacts with aniline and other organic bases.

Curative Effect of Acids in Breathed Air.—It is reported by Dr. VON KAPFF in *Die Umschau* (vol. 24, pp. 45-8, 1920) that the presence of a small quantity of a gaseous acid in the atmosphere if not breathed to excess is not only not injurious but tends to prevent and even to exert a curative effect on diseases of the air passages. The amount should not exceed 0.1 to 0.2 g. per cu.m. and the breathing was continued in his tests for two or more hours daily. The acids employed were hydrochloric, hydrofluoric, sulphurous (SO_2), formic and acetic, and he found the stronger inorganic acids the better curative agents. He claims that the reaction of the mucous membrane is kept acid by the inhalations and that as a result pathogenic organisms cannot grow there. The curative effect is said to be due to the production of hyperemia and possibly the consequent stimulation of the body cells to increase the alkalinity of the blood. The conclusions are reached from experiments made by the author and also from experience with workmen in various industries.

Relative Action of Acids on Enamels.—The progress report of the Sub-Committee on Enamels as printed in the July, 1920, issue of the *Journal* of the American Ceramic Society represents a very large amount of carefully executed experimental work and discloses material progress in arriving at the desired result, to the profit of manufacturers of enameled ware.

It was found that citric acid offers a fairer means of testing enameled coatings than does tartaric acid. Using two different frits and plotting curves, it was noted that there is a reasonable uniformity of action around 15 per cent acid, small variations of concentration in either direction making but slight effect in the total activity. This figure was therefore decided upon. Temperature variations were then studied with a 15 per cent solution of citric acid. Range of 15 to 35 deg. C. was found to materially affect the results. Commercial citric acid was found to be of sufficient purity to give uniform results. Six ounces of acid in one quart of water gives a 15.73 per cent solution and was used for the tests.

Tests were made over 24-hr. periods under tempera-

tures ranging from 12 to 20 deg. C. The etching by acid was determined by rubbing finely-ground charcoal on the surface of the ware, producing definite discoloration in the etched portions below the liquor line and none above. A 3 g.p.l. solution of malachite green was also used, being allowed to stand five minutes and the dishes being rinsed out. The resultant discoloration of etched portions gave more uniform results with varying strengths of acid than in the case of charcoal. The experimental work is still under way.

The Concentration of Graphite Ores, Past and Present.—The first graphite mill in Canada began operations about fifty years ago, using a buddle as a concentrating device. Ore was broken in crushers and stamps and roughly classified, the products being fed to buddles which produced concentrates, middlings and tailings. Middlings were re-treated in buddles. The concentrate was treated by the buhr stones and screens. The latest mills use flotation as an essential step in the process, the concentrate being treated by buhr stones and screens, or, in some cases, rolls may be substituted for the buhr stones. In the Aug. 20 issue of the *Canadian Mining Journal* is published an article by R. C. ROWE describing the development in the processes, together with a brief discussion of the limitations of the flotation process as applied to graphite ores, from which the following is abstracted.

Canadian graphite occurs principally in more or less flat flakes ranging in size from $\frac{1}{8}$ in. in diameter to microscopic dimensions and disseminated throughout the accompanying rocks. The specific gravity is about 2.2 for the graphite and 2.6 for the gangue. As the chief use of graphite is in the manufacture of crucibles and as only the larger flakes can be used for this purpose, the efficiency of any process of concentration is determined to some extent by the quantity of crucible flake recovered.

As the graphite and gangue are of about the same specific gravity, it is difficult to obtain efficient recovery using gravity methods of concentration only, and all efforts in concentrating previous to the use of flotation may be considered commercial failures, although used extensively previous to the introduction of flotation processes. The use of buddles in a wet process of concentration has been noted. A dry process has been used for some time which consisted of drying the ore in rotary kilns or driers, grinding to produce a minus 20-mesh product which was fed to high-speed flour rolls. The principle of the process was that the flake, being flat and tough, would pass through the rolls uninjured, while the gangue, being friable and granular, would be pulverized and could subsequently be removed from the flake by screening. The roll product was screened over 40-mesh and the fine material re-treated by rolls and finer screens. The most recent mills use rolls and screens for treating high-grade concentrate, but this method when used on 10 to 12 per cent ore was not efficient, due to excessive destruction of the flake graphite, to excessive wear of both rolls and screens and to low recovery. A plant using wet crushing, grinding, classifying and tabling was next built, and although the small difference in specific gravity between the graphite and gangue caused difficulty the plant was the most successful working on disseminated ores previous to the adoption of flotation.

The use of gravity methods for concentration brought out the fact that the graphite is intimately

intercrystallized with the gangue material and requires fine grinding in order to liberate the graphite. This is an important point to be considered in the application of flotation processes to graphite ores and emphasizes the problem of proper grinding in order to obtain satisfactory recovery. It has been found that the flake graphite is freed more easily from decomposed than from undecomposed ores and that decomposition appears to free the flake graphite in a manner impossible to duplicate mechanically.

Mechanical and pneumatic flotation machines give practically the same result, the former giving a slightly lower tailing product and the latter a slightly higher grade concentrate. The concentrate from the rougher cells will contain from 30 to 45 per cent carbon.

Three methods may be used to increase the grade of the rough concentrate: (1) Successive flotation, the tailing product being re-treated. (2) Stage grinding followed by flotation. (3) The use of concentrating tables. The first method is the simplest, but it is doubtful whether a high-grade concentrate can be produced. By the second method a high-grade concentrate can be produced, but the successive grinding of the tailing products causes the destruction of a large amount of flake graphite. The use of concentrating tables appears best suited to general requirements, as theoretically the free flake can be removed and is therefore not destroyed in the regrinding of the tailing product from the tables. In practice, however, it is found to be difficult to completely break down the primary froth, and an oil streak which passes down the table with the head water results, which lowers the grade of the table concentrate. A careful selection of the flotation oil may help reduce the loss.

By means of any of the above methods a concentrate containing from 65 to 85 per cent graphite carbon may be obtained, with 75 per cent a fair average grade. The first method is applicable to soft friable ores. With undecomposed gneissic ores the second and third, either separately or in combination, may be used with good results. The first and the third methods yield a higher proportion of No. 1 flake, while the second probably results in a higher grade combined concentrate.

The results that may be obtained by the use of the flotation process have resulted in a distinctly optimistic trend of thought regarding the graphite industry, but it must be pointed out that the industry on this continent has suffered through the acceptance of theory alone as a basis of mill design. The application of the flotation process to graphite ores is not a simple thing and the easy acceptance of theory may result in failure. Each step in the process should be proved to be satisfactory by mill-scale tests, and the advisability of testing cannot be too strongly emphasized.

Easton, Pa., Sewage Disposal Plant.—Bulletin 200 of the National Lime Association contains a description of a sewage disposal plant at Easton, Pa., which has been in successful operation for two years. The raw sewage is first screened, and then passed into an inclosed cypress tank in which are placed electrodes made of mild steel plates 10 x 16 x $\frac{1}{4}$ in. arranged in banks of forty-eight with revolving paddles between the successive pairs of plates. The tank is provided with vents to remove gaseous products, and

lime is added to keep the electrodes in a "passive condition" to conduct the current, making possible the liberation of nascent oxygen, and to aid in precipitating the organic material. The advantages claimed are direct, positive and controlled operation of the process, efficiency in the destruction of solid organic material and that the disinfection and purification of the effluent are high. The plant may be located in a vacant lot within the city limits, thus avoiding the need of long trunk sewers and the attendant expense and debt. The Easton plant is said to be on a residence street within the city, and to give no offense to adjoining property owners.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Refining Lead.—A process for dezinking lead consists in heating the molten lead with a molten mixture of an alkali chloride and a substance which lowers the melting point of the alkali chloride, e.g. a caustic alkali, or zinc chloride in the presence of a source of oxygen such as air or litharge. The treatment of lead with a mixture of zinc chloride and litharge is also referred to. (Br. Pat. 142,315—1919. H. HARRIS, London, June 30, 1920.)

Apparatus for Distilling Heavy Hydrocarbons.—In an apparatus for distilling heavy hydrocarbons such as petroleum, lignite tar and coal tar, and for producing coke, a boiler which is not exposed to the greatest heat of the flue gases is formed with a number of extensions forming retorts on which the fire gases play, the dimensions of the boiler and retorts being such that the solid residue to be coked resulting from the distillation of a charge which fits the whole apparatus is just sufficient to fill the retorts. In the arrangement shown in the accompanying figure the retorts *e*, which are preferably of conical form as shown, are attached to the bottom of the boiler *a* by horizontal branches and are furnished with cleaning

doors *f'* above and discharge doors *f* below. In another form the retorts are attached directly to the boiler and cleaned from within it. Brickwork *n* shields the boiler from the direct heat of the fire gases, but it may be heated by gases escaping to the main flue. The portions of the retorts *e* in the fire-gas chamber are preferably connected to the upper part by flanges, so as to be easily detached for repair. In a modification each retort is connected to a separate boiler chamber with pipes and valves for filling and leading away gas, an arrangement of dampers being provided for regulating the supply of heat to the various retorts. Steam may be injected into the bottom of the retorts to equalize the heating of the liquid. (Br. Pat. 142,376—1919. L. STEINSCHNEIDER, Brunn-Königsfeld, Czechoslovakia, June 30, 1920.)

Destructive Distillation Furnace.—Relates to a vertical shaft furnace for the distillation of asphalt rock, bituminous slate, etc., for producing oil, of the kind in which the distillation is carried out in part of the same chamber as that in which combustion of a part of the material takes place. The furnace comprises a vertical channel 3 having a restricted cross-sectional area 2 at or near the center part for a combustion zone and a lower heat recovery zone 1 of comparatively large depth and diameter. Tuyeres 4 are provided at the bottom of the lower zone which communicate with two channels 5, 6 to supply air for combustion and steam or gas respectively. The heat recovery zone 1 narrows downwardly to the shoot 8, which is closed by a shutter 9. The gases from distillation and combustion are withdrawn through a pipe 11. (Br. Pat. 142,541—1919. A. LA PORTA, Rome, and R. BARTOLOMEIS, Milan, Italy. July 7, 1920.)

Aircraft Fabrics.—A process for preparing impervious fabric for airships consists in treating a fabric of cotton or other fabric having cellulose as its principal constituent by suitable chemical means to convert the cellulose partly or wholly into cellulose acetate, then treating with softening agents, such as triacetine or castor oil, and finally calendering. Any ordinary method of acetylation may be used. For example, the fabric is treated for several hours, at a temperature below 50 deg. C., with double its weight of mixture consisting of 5 to 6 parts acetic anhydride, 4 to 5 parts glacial acetic acid, and 1 part fused zinc chloride. After treatment with the softening-agent and calendering, the fabric may be coated with cellulose-acetate or like dope, and varnished. (Br. Pat. 142,615—1919. VICKERS, LTD., and Sir J. McKECHNIE, Westminster, and A. RYAN, Oldham, Lancashire, July 7, 1920.)

Monoazo and Primary Disazo Dyes.—Monoazo and primary disazo dyes are obtained by coupling one or two molecular parts of a diazotized *o*-aminooxyarylsulphonamide of the formula $(OH)(NH_2)R-SO_2NHX$ (R = aryl or substituted aryl, X = hydrogen or aryl), or one molecular part of such a diazo compound and one molecular part of an aromatic *o*-oxydiazo compound, with one molecular part of an *N*-substituted derivative of 2:5:7-aminonaphthol sulphonic acid, such as phenyl-2:5:7-acid, benzoyl-2:5:7-acid, *m*-aminobenzoyl-2:5:7-acid, the urea of 2:5:7-acid, 5:5'-dioxy-2:2'-dinaphthylamine-7:7'-disulphonic acid, or the urea of *m*-aminobenzoyl-2:5:7-acid. The products are substantive cotton dyes, and may be converted in substance into copper compounds by treating the solutions of dyes with copper or copper compounds, or by coupling the dye components in the presence of copper or its compounds; the copper compounds may also be produced on the fiber by after-treatment with copper salts of the direct dyeings or prints of the dyes, or by dyeing or printing with the dyes in the presence of a copper salt; the copper compounds give bordeaux to violet shades on cotton. Examples are given of the preparation of: a monoazo dye from 6-nitro-2-amino-1-oxyben-

zene-4-sulphonamide and phenyl-2:5:7-acid; a disazo dye from two molecular parts of 2-amino-1-oxybenzene-4-sulphonamide and 5:5'-dioxy-2:2'-dinaphthylamine-7:7'-disulphonic acid; a disazo dye from two molecular parts of 2-amino-1-oxybenzene-4-sulphonamide and the urea of 2:5:7-acid; a disazo dye from two molecular parts of 2-amino-1-oxybenzene-4-sulphonamide and the urea of 2:5:7-acid; a disazo dye from two molecular parts of 2-amino-1-oxybenzene-4-sulphonamide, 2-amino-1-oxybenzene-4-sulphonic acid, and 5:5'-dioxy-2:2'-dinaphthylamine-7:7'-disulphonic acid. (Br. Pat. 142,448—1919. GES FÜR CHEMISCHE INDUSTRIE IN BASEL, Basel, Switzerland, July 7, 1920.)

Metal Heating Furnace.—A furnace for hardening or tempering small metal articles in a non-oxidizing atmosphere comprises a heating-chamber *A* separated from the combustion chamber *B* and having beneath it a chute *D* through which articles tipped or dislodged from the hearth will fall into the quenching-bath *C* without being exposed to the air. The hearth *a* is preferably pivoted as shown, or it may be mounted to slide, the articles being dislodged by a fixed rake; or where the hearth is fixed, a movable rake may be used to discharge the articles into the quenching-bath. Combustible gas is supplied to the chute *D* and heating-chamber *A* through the connection *d*, and openings may be formed in the roof of the heating-chamber through which part of the gas may enter the combustion cham-

ber. A basket *d'* supported by the chute is provided to receive the discharged articles, and a screw pump may be fitted to maintain circulation of the liquid in the quenching-bath. The furnace is gas-fired, preferably by a burner of the kind described in Specification 110,960. (Br. Pat. 142,671—1919. H. W. YATES, Birmingham, and S. N. BRAYSHAW and E. R. BRAYSHAW, Manchester, July 7, 1920.)

Enamels.—Enamels are made, without boron, lead, arsenic, milk glass or opal glass, from a mixture of silicates of alumina, soda, and lime and fluorides, fused and ground, coloring matter such as metallic oxides being added during the grinding process. Carbonate of ammonia may be added if desired, and the composition so obtained is applied to articles and heated to temperatures ranging between 800 and 1,050 deg. C. The limits between which the proportions of the ingredients may be varied are given. (Br. Pat. 142,688—1919. G. MUSIOL, Brussels, July 7, 1920.)

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Recovery of Sulphur Dioxide From Furnace Gases.

A. H. EUSTIS, of Milton, Mass., has been granted two patents covering a method and an apparatus for the recovery of sulphur dioxide from smelter smoke and other gases. The method consists essentially of absorbing the sulphur dioxide from the gases in water, from which it is liberated by heating the solution. The sulphur dioxide is then condensed by pressure and cooling. The principal objects of the invention are to protect from corrosion the pumps by which the gases are handled; to utilize a portion of the liquid SO_2 ; to remove substantially the last traces of moisture from the gases, thereby eliminating dessicators for drying the gas, and to combine in a vacuum chamber the functions of a gas extractor and a condenser for the steam engine of a power plant, thus eliminating the usual heat exchanger. The apparatus is illustrated in the sketch. Gases containing SO_2 are led through flue 1

to the hot tower 2, the principal function of which is to cool, clean and enrich the gases. From the tower 2 the gases pass through flue 3 into scrubbing towers 4a to 4d in parallel, thence by flue 5 to scrubbing towers 6a to 6d in parallel, thence by flue 7 to lime tower 8, and thence by flue 9 to the atmosphere. The towers are all of similar construction and all except tower 8 are filled with coke or other insoluble material. The limestone or other soluble material in tower 8 increases the capacity of the liquid to absorb SO_2 .

Water is fed to the scrubbing towers of the 6 group and to the tower 8 through pipe 10. The water from tower 8 may be wasted or fed to scrubbers of the 4 or the 6 group. The water from the towers of the 6 group is disposed of in three ways; part of it may be delivered through valve 11b to the top of the hot tower 2, when it will be heated by the incoming gases and give up its SO_2 ; part will be used to supply the towers of the 4 group and part wasted through valve 11a. The solution from the 4 group is collected in pipe 12, part being delivered through valve 12a to the hot tower 2, the remainder being delivered to a storage tank 13.

From the tank 13 the solution is pumped through the pipe 15 to the top of the chamber 16, the upper part of which constitutes a douche tank to cool the gases and the lower part of which constitutes a vacuum extractor. The tank is provided with a series of perforated shelves, 17 and 18, designed as shown at A and B. The

descending solutions are subjected in the lower part of the tank 16 to the combined effect of heat and vacuum by which the SO_2 gas is liberated from the liquor. The heat is supplied by exhaust steam from the steam engine 23, the vacuum being produced by pumps 24a, 24b and 24c. The concentrated SO_2 gas passes through the coolers 21, to the pump 24a, through cooler 26a, to pump 24b, through cooler 26b, to pump 24c, and through cooler 26c to the cooling chamber 30. The repeated compression and cooling of the gases progressively removes the moisture and effects a saving of power. A further advantage is that it is possible to keep the temperature of the pump above the dew point of the gases and thereby prevent damage to the pump. If a single stage compression be used instead enough heat is generated by the compression to necessitate water cooling of the pump and this cooling is liable to cause condensation of SO_2 on the walls of the pump with resultant damage thereto.

The cooled and dried gases from cooler 30 pass through pipe 31 to pump 32 and are delivered to condenser 33 through the trap 35, which contains liquid SO_2 and acts as a dessicator to absorb the last traces of moisture from the gas. The trap is filled with coke and is cooled by the water coil 35b to such temperature that a portion of the SO_2 is liquefied. The liquid SO_2 from the trap is blown into cooling chamber 30 through pipe 36, when by expansion it refrigerates the cooler and gives up at least a portion of the moisture, which is removed through valve 30a. The pumps are provided with jackets for the purpose of keeping the walls above the dew point temperature and thus prevent corrosion. (1,341,114; May 25, 1920.)

Use of Oil in Drying Ores.—Certain iron ores found in parts of the Mesaba region and in other parts of the country contain a high percentage of moisture and are so lean that practically all of the moisture must be removed to raise the iron content of the ore to a commercially workable percentage. In drying these ores it has been found that at about 7 per cent of moisture the ores become so dusty that they cannot be transported or used in a blast furnace without undesirable loss. GEORGE L. COLLORD has found that if an oleaginous material such as tar or some form of petroleum be added to the moist ores, either before or while drying, such oil will spread over the ore particles and form a protective coating on all of the particles of the ore, and when so coated the percentage of moisture can be reduced to 3 per cent without the ore disintegrating in the process of drying. It has been found that 2½ to 3 per cent of oil or tar will be sufficient to coat all particles and that when the oil treated ore is dried to about 2 to 3 per cent of moisture the film coated materials will assume a granular form and will be entirely free from dust. (1,343,249; June 15, 1920.)

High-Speed Cutting-Tool Alloy.—Various combinations of elements may be made to produce alloys useful for specific purposes, and one invented by HUGH S. COOPER of Cleveland illustrates the possibilities in this direction. A high-speed cutting-tool that gives satisfactory service may be made by alloying zirconium, silicon and aluminum with nickel in the following proportions: Zr, 0.5 to 2 per cent; Si + Al, 2 to 8 per cent; the remainder of the alloy being Ni with small incidental amounts of iron, and, if desirable, tungsten. (1,350,359, assigned to the Zircon Tool & Alloy Corp.; Aug. 24, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Chemical Exposition Opens in New York

Larger and more inclusive as to exhibits and more interesting as to program and entertainment than any of its five predecessors, the Sixth National Exposition of Chemical Industries was formally opened in Grand Central Palace, New York, on Monday, Sept. 20, with an address by Dr. Charles H. Herty. He was followed by Dr. Charles L. Reese, chief chemist for the du Pont company, who spoke on "Co-operation in the Industries." Dr. Reese drew attention to the paramount importance of co-operation among all interests concerned in the chemical industry. He pointed out as an example the fact that although exact measurements are the very foundation of chemical science, yet these measurements are made by physical instruments prepared by those who are not chemists. As a consequence co-operation between chemists and manufacturers of physical apparatus for controlling chemical processes is an outstanding necessity. The mutual benefit to be derived would be welcomed by both the chemist and the equipment maker. Dr. Reese stated that a beginning had been made in this direction by the association of some of the large chemical manufacturers of the country for the purpose of deciding upon standard specifications for certain chemical equipment, particularly thermometers.

The speaker also pointed out the value of co-operation among chemists in exchanging information and in concentrating on the solution of fundamental problems which are of interest to the entire profession. As an example he cited the need for material which resists aqueous hydrochloric acid at high temperatures. This is but one of the many problems which he thought would be solved if there were closer co-operation.

Problems confronting the American exporter were discussed by Erastus Hopkins of Gaston, Williams & Wigmore, Inc. Mr. Hopkins' paper dealt generally with a few fundamental suggestions which relate not only to chemical export trade but to American trade in general. He criticized the American selling organization for not studying the successful methods of other countries, such as England and Germany. This is believed to be necessary because Americans are not in any sense colonists nor do they have the foreign outlook as do the English and the Germans. He emphasized the necessity of shipping goods which meet exactly the specifications of the buyer, this being one phase of the service which must be rendered. Another phase is promptness in delivery. The speaker touched upon the matter of packing goods for export and contrasted the methods of English and American manufacturers in this respect. In the matter of financing the American exporter still has much to learn. Business cannot be done on a cash basis and the manufacturer must bear his share of the burden of financing his export business.

The fuel symposium, which was held Tuesday afternoon, Sept. 21, was devoted to the subject of fuel conservation and methods of getting additional energy out

of the country's fuel supply. A full report of this symposium will be given later.

The motion picture programs are an excellent feature of the Exposition and will do much toward giving the public a sense of the importance of the chemical industry in the United States. Such films as modern packaging methods, the production of salt, the story of sulphuric acid and others are proving very attractive. Advantage is being taken of Exposition week for the gathering of several organizations, among them being the Chemical Warfare Post of the American Legion, the chemical fraternity Alpha Chi Sigma, and the American Institute of Chemical Engineers. The complete story of the Exposition and report of the technical sessions will be given in our issue for Oct. 6.

American Foundrymen's Association Meeting

The 1920 convention and exhibition of the American Foundrymen's Association, together with the Institute of Metals Division of the A.I.M.E., will be held at Columbus, Ohio, during the week of Oct. 4.

The tentative program contains many interesting and important papers to be presented on various aspects of Gray Iron, Non-Ferrous Practice, Steel, Industrial Relations, Metallography and Malleable Iron. Among these are "A Note on the Electric Furnace and the Problem of Sulphur in Cast Iron," by George K. Elliott; "Steel Making," by James W. Galvin; "The Triplex Process of Making Malleable Iron," by H. A. Schwartz, and "Approved Methods of Testing Molding Sand," by S. W. Stratton.

The convention will close Friday, Oct. 8, with an important exhibition by about 200 exhibitors of equipment and products, and a big meeting with the Electric Furnace Association.

Minerals Separation, Ltd., Appeals Case

Minerals Separation, Ltd., has appealed from the recent decision of Judge Morris, of the U. S. District Court of Delaware—the decision upon which that judge had based his various orders dismissing the different contempt proceedings through which Minerals Separation has unsuccessfully attempted to have Miami Copper Co. declared in contempt of court for continuing the use of its flotation process. By this new proceeding Minerals Separation now seeks to bring its assertion of contempt before the U. S. Circuit Court of Appeals in Philadelphia.

American Tar Products Co. Sold

The Koppers Co. and the Aluminum Co. of America, both of Pittsburgh, have jointly purchased the American Tar Products Co. and will operate it together. It is planned that operations shall include manufacture of electrodes for the use of the Aluminum Co., as well as a continuance of the general tar-refining work.

Cleveland Meeting of the American Electrochemical Society

The thirtieth general meeting of the American Electrochemical Society will be held in Cleveland Sept. 30, Oct. 1 and 2, 1920, under the auspices of the local members and the courteous co-operation of the Cleveland Engineering Society and the Cleveland Section of the American Chemical Society. Headquarters will be at the Hotel Statler. The morning sessions of Thursday, Sept. 30, and Saturday, Oct. 2, will be held in the ballroom of the hotel, but the session of Friday morning, Oct. 1, will be held in the physics lecture room of the Case School of Applied Science. An excellent technical program has been arranged as well as visits to plants of the Cleveland Instrument Co., U. S. Malleable Castings Co., Ohio Chemical Co., Cleveland Metal Products Co., Guide Motor Lamp Co. and Western Reserve Chemical Co. The social features will comprise a complimentary smoker in the ballroom of the Hotel Statler Thursday evening, Sept. 30, and an informal subscription dinner and dance in the ballroom of the hotel Friday evening, Oct. 1. Special arrangements have been made for the entertainment of visiting ladies. A feature of the meeting will be a visit to the Nela Park laboratories of the General Electric Co., where a special program will be arranged.

Lemon Growers Utilize Byproducts of the Lemon Industry

Another example of the way the chemists are conserving and economizing nature's resources is the work done at Corona, Cal., by the Exchange By-Products Co., which is owned and operated by the lemon growers of the California Fruit Growers Exchange. Large quantities of lemons which, because of their small size or some other good reason, would not be marketable and ordinarily a total loss have been salvaged and turned into profit. This byproducts plant is reported to have utilized ninety-four tons of lemons a day during the month of July and to have prepared and made use of 15,000 gal. of lemon juice per day during this time.

United States Not to Buy German Drugs

No German chemical drugs manufactured during the first half of the current year are to be purchased by the United States from stocks impounded in Germany. This applies to the synthetic organics of commerce and to practically all of the German patented products. The United States retains its right to make purchases during the next four and one-half years on the possibility that the present sufficiency of chemical drugs might not be obtainable from domestic sources. The statement in this connection issued by the War Trade Board Section of the Department of State follows in its entirety:

The Reparation Commission has offered to this Government the right to participate in the purchase of certain chemical drugs from stocks impounded in Germany as well as from subsequent production of German manufacturers, rendered available to the commission by the Treaty of Versailles.

From the records in possession of the War Trade Board Section it would appear that practically all these chemical drugs are now being manufactured in this country. They are available to the American consumer on reasonable terms as to price, quality and production. Reliable reports indicate the domestic product is equal to the German in quality; that the average price is substantially the same as that asked by the German manufacturers for stocks of current produc-

tion, and that these drugs are manufactured in this country in quantity sufficient to meet all indicated domestic demand. The foregoing covers not only synthetic organics of commerce but likewise practically all of the German patented products.

From the foregoing it would seem that there is no present need or demand in this country for these chemical drugs of German manufacture. For this reason this Government does not feel it advisable to take active steps to place upon the market foreign-made drugs which would compete with those of domestic manufacture and therefore will not exercise its option upon impounded stocks of chemical drugs of German manufacture or upon stocks of chemical drugs manufactured during the months of January, 1920, to June, 1920, inclusive.

This Government will, however, retain its right to participate in allotments from future daily production of chemical drugs which may be manufactured by Germany during the next four and one-half years, in view of the possibility that a need in this country may arise at some future time for certain chemical drugs which may at that period be unobtainable from domestic

Pulp Situation at Holyoke Mills Easier

The general improvement in traffic conditions has eased the pulp situation in the Holyoke district. As there is but one pulp mill in the immediate vicinity, the mills are absolutely dependent on the railroads and consequently any impairment in service is felt immediately. Shutdowns of a day or two at a time caused by lack of pulp were common through the early part of the summer. The larger companies, by rationing each car of pulp consigned to them, were able to keep their divisions operating.

In common with the rest of New England, Holyoke has suffered from the coal shortage. The mills are for the most part operated on water power but of course depend on coal for raising what steam is needed, and supplies have been very short. The local gas and electric company has barely been able to keep going by borrowing needed coal from the local mills fortunate enough to have a surplus and from nearby cities where a carload or so at a time could be picked up.

Conference of Color Committee of Cottonseed Oil Chemists

A conference dealing with the color standardization of oils was held at the Bureau of Standards on July 30 and 31. The entire subject was discussed in detail, including the use of technical terms, the present difficulty in getting instrument makers to turn out the required apparatus, and a demonstration of the methods used in color grading oils by the optical division of the Bureau. The new apparatus recently designed for this purpose was demonstrated and a great deal of time spent in familiarizing the committee with the use of the instrument. Data secured were compared with the results obtained from the Arons chromoscope in terms of Lovibond numbers. Data were also secured on some of the samples by means of the Koenig-Martens spectrophotometer.

Memorial to Lord Rayleigh

The Rayleigh Memorial Committee has decided that the mural tablet to the late Lord Rayleigh, which is to be placed in Westminster Abbey, shall be erected in close proximity to the memorial to Sir Humphry Davy. As there will be a balance remaining after all expenses have been met, it is proposed that this shall be used to establish a library fund at the Cavendish Laboratory, Cambridge.

Philadelphia Section Meeting, A. C. S.

The first meeting of the Philadelphia Section, American Chemical Society, for the 1920-21 season, was held at the Engineers' Club Thursday evening, Sept. 16.

For the benefit of those members who were unable to attend the sixtieth meeting of the Society at Chicago, Dr. R. P. Fischelis outlined the general features of the meeting, devoting particular attention to matters discussed at the Council meeting. An item of local interest was the change in name of the Carney's Point Section to the South Jersey Section.

Dr. W. A. Pearson announced that Sydney Davis has found it impossible to continue as editor of the *Catalyst*, owing to business interests which require his full time outside of Philadelphia. A vote of thanks was tendered Mr. Davis and Dr. Fischelis, managing editor of the *Catalyst*, who is to leave Philadelphia in the near future. In order to fill these vacancies, Dr. Henry Leffmann will be asked to accept the position of editor and Dr. Joseph S. Hepburn that of associate editor.

NITROCELLULOSE

Hugo Schlatter, chief of the Chemical Products Division, Hercules Powder Co., reviewed the development of the nitrocellulose industry, which dates from Schönbein's discoveries in 1846, and then discussed the chemistry, manufacture and uses of nitrocellulose.

CHEMISTRY OF CELLULOSE

The product obtained by treating cellulose with mixed acid is a true ester and not a nitro compound, so that we should speak of cellulose nitrate and not nitrocellulose. The products obtained are not definite compounds since the raw material—cellulose—is complex. In nitrocellulose work, n in the formula $(C_6H_7O_2)_n$ is taken as 4. Of the structural formulas, that of Green best explains the formation of dextrose and brom-methyl-furfural. Hibbert's formula consists of a 5- and a 6-membered ring (instead of the 5- and 7-membered ring of Green) and explains polymerization. Our knowledge of the cellulose molecule is, however, still very meager.

MANUFACTURE OF NITROCELLULOSE

The chief source of cellulose for nitration is cotton linters. These are cleaned, freed from oil by boiling under pressure with 2 per cent NaOH solution (in the absence of air, which would form oxycellulose), dried to less than 1 per cent moisture and then treated with mixed acid, the composition of which varies according to the product desired. The nitrated products have the formula $C_{24}H_{40-n}O_{20-n}(ONO_2)_n$, where n may vary from 1 to 12, although only those nitrocelluloses in which n is 7 or over are of commercial importance. As a general rule, nitrocellulose containing over 12 per cent N is insoluble in ether-alcohol and is used as gun cotton, while when the nitrogen content is below 12 per cent the product is suitable for the manufacture of pyroxylin plastics.

The modern system of manufacture consists in treating the cellulose in small batches in dipping pots which discharge to centrifugals on the floor below. These in turn discharge into washing bowls provided with a tangential flow of water. It has been found that instability of the product was due to the presence of nitration products of impurities in the raw cellulose. These are broken up by boiling with water containing a little acid. The material is next passed through beating engines, which reduce the fibers so that they will pass through

0.01-in. slits. A final boiling or "poaching" serves to remove the last traces of acid from the capillary fibers. After drying to 30 per cent moisture in centrifugals, the nitrocellulose is placed in hydraulic presses having a perforated plate through which alcohol is forced, to displace the water in the nitrocellulose. The alcohol is then removed by a pressure of 3,500 lb. per sq.in.

The speaker concluded with a summary of the varied uses of nitrocellulose for military and industrial purposes.

DISCUSSION

In reply to a question by Dr. E. E. Marbaker as to the difference between high and low viscosity cottons, Mr. Schlatter said that the viscosity could be varied over a wide range through the proper choice of solvents coupled with the use of diluents or non-solvents. Solutions of very high viscosity are obtained when non-solvents are added in amounts just insufficient to cause precipitation. This phenomenon is the basis of one of the methods for preparing solid alcohol. Viscosity is determined with sufficient accuracy for practical purposes by noting the time required for a steel ball to fall 10 in. in a vertical tube filled with the solution to be tested. This time may vary from 5 to 1,200 sec.

Dr. Marbaker also inquired as to the cause of "blushing" or the appearance of opaque, poorly-adherent spots in the coating of split leather when dopes containing highly volatile solvents are used. Mr. Schlatter said that this was due to the relatively greater hygroscopicity of such dopes and to the fact that the rapid evaporation of the solvent often cools the surface below the dew-point of the surrounding atmosphere so that moisture condenses on the coating, causing precipitation of the nitrocellulose.

Ceramic Day at the Chemical Exposition

The American Ceramic Society is occupying Booth 750, on the fourth floor, at the Sixth National Exposition of Chemical Industries, Grand Central Palace, New York City. A program of diversified interest will be given on Ceramic Day, Friday, Sept. 24, at 2 p.m. In the evening of the same day moving pictures will be shown of different phases of the ceramic industry. Members and persons interested are invited to register at the booth, where the Society's literature may be examined, orders left, application blanks obtained, etc. The assistant secretary will be in attendance each day to give information and to receive registrations and memberships.

Another Platinum Theft

The following pieces of platinum were recently stolen from the chemical laboratory of the United States Smelting, Refining & Mining Co., at Midvale, Utah:

Cylinders	No. on Cyl.	Size of Cyl. In.	Wt. of Platinum, G.	Size of Cylinders
1 (B & Co. on stem)	6	1	17.0008	4 1/2 in. x 2 in.—5 1/2 in. stem
1 (B & Co. on stem)	31	1	15.6975	4 1/2 in. x 2 in.—5 1/2 in. stem
1 (B & Co. on stem)	25	1	15.4663	4 1/2 in. x 2 in.—5 1/2 in. stem
1 (B & Co. on stem)	29	1	15.6008	4 1/2 in. x 2 in.—5 1/2 in. stem
1 (B & Co. on stem)	1	3/16	11.50	3 1/2 in. x 2 in.—4 in. stem
1 (B & Co. on stem)	3	3/16	11.50	3 1/2 in. x 2 in.—4 in. stem
1 (B & Co. on stem)	5	3/16	11.50	3 1/2 in. x 2 in.—4 in. stem
1 (B & Co. on stem)	6	3/16	11.50	3 1/2 in. x 2 in.—4 in. stem
1 (B & Co. on stem)	7	3/16	11.50	3 1/2 in. x 2 in.—4 in. stem
1 (B & Co. on stem)	9	3/16	11.50	3 1/2 in. x 2 in.—4 in. stem
2 Spirals			about 6 g. each	4 1/2 in. long—1 in. flat co. 1
2 Crucibles			about 20 g. each	
2 Crucible covers			about 5 g. each	
3 Filtering cones			about 2 g. each	

Imports and Exports of Chemicals

Exports of chemicals during the seven months ended with July ran well ahead of the corresponding period of 1919. The value of chemicals exported during the first seven months of 1920 was \$106,633,166, as compared with \$75,299,068 for the first seven months of 1919. These figures are taken from the returns to the Bureau of Foreign and Domestic Commerce, which has just completed the compilation of the July returns.

In July, the value of chemicals exported was \$13,775,972, as compared with \$7,642,735 in July of 1919. The sodas contributed greatly to the increase. Sodas were exported in July, 1920, to the value of \$2,133,239. The principal increase was in caustic soda exports. Dyes and dyestuffs also increased markedly. Exports in July, 1920, were valued at \$3,018,188, as compared with \$872,091 in July of 1919. France, Italy, the United Kingdom, Canada, China and Japan were the destinations of greatly increased quantities of dyes.

While the exports of acids were light, valued at \$426,340, there was a very marked increase in exports of sulphuric acid. The exports of extracts for tanning fell off slightly, totaling for July, 1920, \$234,310.

Imports of chemicals more than doubled in July, 1920, as compared with those of July, 1919. The total value of chemicals imported without the payment of duty in July, 1920, was \$11,249,624, compared with \$3,816,142 in July of 1919. The value of the dutiable chemicals imported in July, 1920, was \$6,640,706. In July, 1919, the imports of dutiable chemicals were valued at \$4,696,731. Of particular significance were the imports of gums. In July, 1920, gum arabic, camphor, chicle, copal, gambier, shellac and other gums were imported to the extent of 18,162,380 lb. Potash imports also were heavy, aggregating 3,394,208 lb. The principal item making up the total was cyanide of potash.

Figures covering chemicals of lesser importance are as follows:

IMPORTS OF CERTAIN CHEMICALS

	July, 1919 Lb.	July, 1920 Lb.
Arsenic, and sulphide of.....	398,291	993,558
Indigo:		
Natural	1,736	none
Synthetic	9,311	164,676
Iodine	83,257	none
Lime, chloride of	101,378	140,562
Lime, citrate of	220,815	781,933
Potash, carbonate of	71,627	794,909

EXPORTS OF CERTAIN CHEMICALS

	July, 1919 Lb.	July, 1920 Lb.
Glycerine	67,980	113,636
Lime:		
Acetate of	908,546	1,388,972
Chloride of	652,226	3,656,024

Appropriations for Chemical Work

No great difficulty is expected in convincing Congress at the next session that more appropriations must be forthcoming for work of interest to the chemical industry. While it is expected that the next Congress will be more generous than the last, information reaching Washington is that the chemical industries are prepared to present such convincing facts and figures as to make a favorable decision in the matter by the Appropriations Committee practically certain. The Appropriations Committee will be shown that from 1914 to 1917 there was an increase of 182 per cent in the volume of business done by the chemical industries. In 1910 the value of exports of thirty-six classes of chemicals aggregated \$21,500,000. In 1917 the exports

of these same classes of chemicals aggregated \$193,000,000. In 1910 imports of seventy-six different groups of chemicals aggregated \$76,500,000. This amount was increased to \$144,000,000 in 1917. In 1910 the United States imported \$55,000,000 worth of chemicals more than were exported. In 1917 the exports exceeded the imports by \$49,000,000.

It also will be pointed out at the next session that the expansion of the chemical industries antedated the war. During the period from 1904 to 1914 the average increase in the value of products of fourteen leading industries was 63.9 per cent. During the same period the value of the products of the chemical industries increased 86.1 per cent. Among the fourteen industries the expansion in the chemical industry was exceeded only by that in the vehicle industry.

It is believed that it will not be difficult to impress upon Congress the enormity of the achievement of the chemical industry in meeting the chemical needs of the country throughout the war, when it was called upon almost over night to take care of needs which previously had been supplied from abroad. This was done in spite of the intricate character of most chemical manufacturing processes.

It is taken for granted that Congress is unanimous in the desire to prevent the decadence of this new industry, but the Appropriations Committee will scrutinize closely any proposed expenditures to assist the industry in holding its own. It will be pointed out to the committee, however, that the maintenance of these great business enterprises, when subject to peace-time competition, will depend to a considerable degree on their efficiency, and that a great number of problems will have to be met if the various advantages held abroad are equalized. There is reason to think that Congress will be ready to lend its aid to end the old practice of exporting the raw materials from which chemicals are made and buying back the finished products at greatly enhanced prices.

Chicago Meeting of the National Association of Purchasing Agents

The National Association of Purchasing Agents will hold its annual convention at the Congress Hotel, Chicago, Oct. 11, 12 and 13. Business sessions will be held on each of those days, the convention being open to all industrial purchasing agents.

At the morning session on Oct. 11 the work of the association in establishing standards of business practice and in national legislative matters will be reviewed. At all other sessions there will be addresses and discussion. Some of the speakers on the program are Russell A. Pettengill, of the Russell A. Pettengill Co., Chicago, on "Buying Through Specifications"; Prof. Irving Fisher, of Yale University, on "Stabilizing the Dollar"; Dr. F. W. Russe, of Mallinckrodt Chemical Works, St. Louis, on "Safeguarding the Purchase of Chemicals."

Visits of inspection will be paid by the delegates to the packing houses of Chicago and to the Great Lakes Naval Training Station.

On the evening of Oct. 11 the annual banquet of the association will be held, featuring speakers of national prominence.

The National Association of Purchasing Agents has a membership of 3,500.

American Engineering Council of the Federated American Engineering Societies to Meet

The first meeting of American Engineering Council of the Federated American Engineering Societies will be held in Washington, D. C., Nov. 18 and 19, 1920, with headquarters at the New Willard Hotel. All sessions will be held in the small ballroom.

Registration will begin at 8:30 a.m. Thursday, Nov. 18, and at 10 o'clock the opening session will be called to order by Richard L. Humphrey, chairman of the Joint Conference Committee. A temporary chairman and secretary will be elected and committees will be appointed on program, credentials, constitution and bylaws, nominations, plan and scope, budget, and resolutions. At the afternoon session J. Parke Channing, chairman of Engineering Council, will address the gathering on the work of that organization. This will be followed by a discussion of the field of activity for the Federated American Engineering Societies.

At 9 o'clock Friday, Nov. 19, the morning session will consider the report on the committee on nominations, election of permanent officers, report of committee on constitution and bylaws, formal ratification of same, and report of committee on plan and scope. At the afternoon session at 2 o'clock the committees on budget and on resolutions will make their reports. The evening session will meet at 8:30 to hear an address by Herbert Hoover, president of the American Institute of Mining and Metallurgical Engineers. This will be followed by an informal reception and smoker.

At 9 a.m. Saturday, Nov. 20, there will be an organization meeting of the executive board, American Engineering Council, of the Federated American Engineering Societies.

Personal

Dr. ARTHUR M. BUSWELL, who was formerly in the department of sanitary engineering at Columbia University, is now chief of the Illinois State Water Survey, Urbana, Ill., having succeeded Prof. Edward Bartow, who is now head of the chemical department of the University of Iowa, Iowa City, Iowa.

Dr. FARRINGTON DANIELS has resigned from the Fixed Nitrogen Research Laboratories, American University, Washington, D. C., to become assistant professor of physical chemistry at the University of Wisconsin.

Dr. J. E. DAY has resigned as assistant professor in Ohio University to accept a similar position with the University of Wisconsin, where he will teach inorganic chemistry.

HARMON E. KEYE, who was with the Consolidated Mining & Smelting Co. of Canada, is now chemist with the Electrolytic Zinc Works, Martinez, Cal.

Dr. R. E. RINDFUSZ has been appointed assistant to the president of the American Writing Paper Co., of Holyoke, Mass. Dr. Rindfusz has been chief of the research section of the company's department of technical control. Previous to his association with this company he was associate in organic chemistry in the University of Illinois and was identified with that institution's war work in the manufacture of rare organic chemicals.

H. H. STOEK has recently received the honorary degree of D.Sc. from the University of Pittsburgh.

A. E. WELLS, chief metallurgical engineer of the Bureau of Mines, has resigned to handle the mining and metallurgical problems of a large development company. His headquarters will be in New York.

Obituary

GEORGE A. BREWSTER, who had been chief chemist and metallurgist with the American Steel Foundries Co., Chicago, Ill., and the American Radiator Co., Buffalo, N. Y., and who had also held other positions in connection with the chemical industry, died on Aug. 17, 1920. Mr. Brewster was an active member of the American Chemical Society, the American Steel Treathers Society and the American Institute of Mining and Metallurgical Engineers, and had accomplished much in the way of development of special steels. He is survived by his wife and two sons.

JOHN R. COOPER, of Degolia, N. Y., who was part owner of the Newton Chemical Co., died on Sept. 3 following an operation.

Dr. WILLIAM HODGSON ELLIS, former dean of the faculty of applied science, Toronto University, died at Lake Joseph, Muskoka, Canada, on Aug. 23, 1920. Although Dr. Ellis was in his seventy-fifth year and had not been as active for the past year as his friends would have wished, his death came as a distinct shock to his colleagues of the university and to a host of graduates throughout Canada. For more than forty years Dr. Ellis had been on the teaching staff of Toronto University. He held various lectureships until 1887, when he became professor of applied chemistry at the school of practical science. He was later made dean of the faculty of applied science, from which he retired in May, 1919.

CHARLES WARREN MCCLURE, vice-president and general manager of the William B. Pollock Co., Youngstown, Ohio, died on Aug. 11, 1920.

Book Reviews

THE OIL-SHALE INDUSTRY. By Victor C. Alderson. 170 pp., illus. New York: F. A. Stokes & Co. Price, \$4.

This book, gotten out "to meet the widespread demand for information of a comprehensive nature," contains a miscellaneous collection of facts, figures and views anent oil shale and the oil-shale industry. It comprises an elaboration and revision of material presented in the *Quarterly of the Colorado School of Mines* for October, 1919. Essentially popular in its nature, it adds nothing to present knowledge of oil shale of value to the engineer or chemist, but much of the information and many of the views presented will be of interest. The book should be in the hands of every person interested in the promotion of an oil-shale project.

After reviewing the critical petroleum situation, which points to the eventual utilization of oil shales, the extent of the world's deposits of oil shale and the history of the shale industry abroad are popularized and presented in pellet form. Many statements in the book are of doubtful accuracy. Chapters on "Retorting and Reduction" and on "Experimental Work" are included, which seem to have been hastily compiled from the popular press. For example, on page 52, we learn that all petroleum consists of hydrocarbons which "belong to one of two series—the paraffine or the olefine series." On page 54, we are told that a hydrocarbon "is primarily a compound of the elements carbon and hydrogen, but combinations of these two with other elements are not excluded." On page 93, experimental work of the United States Geological Survey is quoted, showing that the yield of ammonia obtained by steam distillation was approximately two and one-half times that obtained by dry distillation, while on page 61 we learn that "It is difficult to see how steam can aid in the formation of ammonia during the distillation of the oil by any chemical interaction."

While the possibilities of the oil-shale industry could hardly be exaggerated and indeed are not exaggerated by Dr. Alderson, his views as to the present status of the industry seem optimistic in view of the fact that all work done up to the present time, however valuable, has been confined strictly to pioneering on a small scale. A number of favorable reports upon the quality of shale oil have been included, and, however authentic these may be, due mention is not made of adverse reports. A method for the determination of oil and ammonia yields from oil shale is included which seems to have many excellent features. A very good bibliography is appended.

The difficulties of presenting information bearing on an industry so embryonic as the American shale-oil industry are, of course, great, and much should be excused in an attempt to describe such an industry. At the same time it seems ill advised to offer to the public a work purporting to convey "comprehensive information" upon a non-existent industry. Especially is this true at a time when governmental agencies are investigating the subject, when many private agencies with conflicting interests and opinions are putting forth conflicting claims and when no technology exists to be described except the Scotch practice, which is presented in this work only in a very general and somewhat fragmentary manner.

CHARLES L. JONES.

Current Market Reports

The Iron and Steel Market

Pittsburgh, September 17, 1920.

Demand for steel products, whether for prompt or for late delivery, continues notably light, and the situation is the more impressive from the fact that more than half of September has been passed, so that the dullness can no longer be ascribed to its being the midsummer period, which is always dull in the steel trade, but which the trade limits in its market analysis to the two months July and August.

As to forward commitments the dullness is ascribed to uncertainties both as to general business and as to prices of steel in particular. As a rule in steel, only a scarcity of material or the certainty that prices are going to be higher will bring the buyer into the market for forward commitments. As to prompt buying, the loosening up in the rail transportation situation is easily sufficient to account for the dullness. Production of steel has increased and the mills are now shipping more than they currently make, instead of less, as was the case in July and three months preceding. The stocks at mills are not cleaned up yet, but are probably reduced to not over one-half the maximum, which fell at about the end of July. Thus there has been a very material increase in receipts of steel by jobbers and manufacturing consumers. The prompt buying that occurred some time ago was not of regular character, but was largely by consumers who had steel due them on regular contracts but who were not receiving full deliveries. Accordingly they doubled up on purchases, buying prompt deliveries to eke out, and now when they receive deliveries from both sources of supply they are, generally speaking, well supplied.

Generalizations, however, are not exact in the matter of the various steel products. While there is no marked demand in the matter of making fresh purchases in any line, there remains considerable pressure on the part of buyers for deliveries against old contracts in several lines, including nails, tin plate and the smaller sizes of merchant steel bars.

STEEL PRODUCTION INCREASING

Here and there, it appears, a small mill is decreasing its operations on account of lean order books, but such cases amount to very little in the general average. The large mills have been increasing production as physical limitations, particularly the matter of transportation, permit.

The report on ingot production made by the American Iron and Steel Institute covers the output of thirty producing companies which contributed 84 per cent of the 1918 total output and 85 per cent of the 1919 total output. The production of these thirty companies increased by 7 per cent from July to August, and the influences permitting larger production have continued. The rate of steel ingot production for the whole country in August may be estimated at about 42,700,000 gross tons per annum. October, usually a very favorable month on account of seasonal conditions, may easily show a rate of 45,000,000 tons.

While the steel market is described as stagnant, it must not be inferred that there is no buying and that no new commitments at all are being made. Scarcely any material is sought in the open market, but the mills are entering more or less tonnage from regular customers quite steadily, the volume being somewhat reduced. Thus the Steel Corporation had bookings in August equal to about two-thirds of its capacity, and its bookings this month may run at about the same rate. The corporation's unfilled obligations decreased by 313,430 tons in August, this being the first decrease reported since that for May, 1919, but the August decrease was equal to only about 23 per cent of the month's capacity, while shipments may be estimated at 90 per cent of capacity, indicating bookings at 67 per cent. July had shown an increase of 139,651 tons in unfilled obligations, equal to 10 per cent of capacity, and if shipments in July be taken at 75 per cent the bookings appear to have been about 85 per cent. The decrease in bookings from July to August is thus about 18 points, while the increase in shipments was about 15 points. With an increase of 139,651 tons in unfilled obligations in July and a decrease of 313,430 tons in August, there was a net change of 450,000 tons, nearly half of which change is attributable to an increase in shipments.

PRICES MAINTAINED

The large independent steel mills are maintaining their prices quite well. There is no disposition to quote prices in the open market lower than prices at which there are unfilled contracts on books, as the net result would be unsatisfactory. For a ton of new business thus secured ten tons of contract business might be jeopardized. Some paper advances recently made, however, have not held. Thus some mills that had sold plates at 3.25c. put their nominal asking price up to 3.50c., but now admit that if real business were offered they would be willing to accept it at 3.25c. To go a single dollar a ton below 3.25c., however, would be an entirely different matter.

Those of the smaller mills that have had prices far above the prices of the larger independents have been disposed to reduce prices, but this represents simply a decrease in delivery premiums. It is difficult to sell even at reduced prices, hence these smaller mills are faced with lower production rates.

As there is no longer any danger of a price advance by the Steel Corporation encouraging the independent steel market to engage in a fresh flight the corporation has relaxed a trifle of its rigidity in holding its prices down to the Industrial Board schedule, promulgated March 21, 1919. Last month the corporation adopted a new card on wire nails, practically conforming to the card adopted by the independents last February and increasing the extras on small sizes above the base price. Since then the corporation has advanced its price on rods \$5 a ton, to \$57, but as the independents are quoting \$70 to \$75 this goes but a short distance toward bridging the gap between corporation and independent prices. It is not certain that the corporation may not reduce some of its prices, its object apparently being to readjust its prices in relation to the cost of production of different commodities. The Industrial Board schedule, to which the corporation has adhered, was not an independent price structure, but was little more than the war control schedule reduced horizontally, while production costs now are not aligned with each other as they were during the war.

Pig iron is stagnant in nearly all districts and practically everyone now feels that the recent price advances were

carried too far, so that the next change in pig iron prices will be in the downward direction. As the merchant furnaces are well filled with business for the nearby future nothing may occur for a while.

The Chemical and Allied Industrial Markets

New York, September 17, 1920.

No improvement in the chemical market has been made during the period. The same "waiting" attitude noticed among buying interests for the past few weeks continues in vogue, with the result that business has been rather dull and in a small way whenever transacted. The shading of firm prices by second hands in an endeavor to obtain the cash with which to lay in stocks for the coming year has fallen off and producers' prices practically govern the market. On the whole former prices have been well sustained, but on the other hand there have been no advances, which seems to indicate that the market will continue in its present inactive condition until there is a better understanding between buyer and seller.

MANY ITEMS WEAKER

The exceptions to the otherwise steady market are those which have been weakening for the past week or two. Among these is *caustic soda*, which has been offered as low as \$4.50 by second hands, but the average price for the usual material is still around \$5.50 per cwt., with buyers showing no inclination to invest. Another item that has been affected by the sluggish condition of the market is *oxalic crystals*, which is quoted on contract at 45@50c. per lb., compared with the recent quotations of 53@54c., and it is not beyond probability that this figure can be lowered to 40c. in the open market for second-hand supplies. Demand for *citric acid* having quickened, there is a decidedly firmer note to this item, although the price has remained the same, it being still possible to obtain material in carloads at 78@81c. per lb. *Potassium bichromate* continues brisk at 35c., with some quotations slightly below this figure and the supply keeping fairly well up to demand.

COAL-TAR PRODUCTS

The change in this market, if it can be called such, is one of attitude rather than actual conditions, as prices are about the same and buying has not been greater than for the past few weeks. This change of attitude is principally on the part of producers who have taken a decidedly optimistic view of the coming season's business and look forward to a heavy year. Indications seem to justify this opinion, as the resumption of activity in the textile trade will beneficially affect business and besides increased activity in the paint industry is expected to be the order for next year. There is no doubt that this market has been as dull for the past few months, after last winter's heavy buying, as it has been for some years and a break was expected, arrived and now a return to better conditions is being looked forward to in the near future.

The only items worth noting are *dimethylaniline*, which picked up after the recent drop and is quoted at 95c.@\$1.05 compared with 80@90c. of the previous report and also *H acid*, which showed some weakness and is in better supply, at \$1.90@\$2.05 per lb., than it has been for some time.

NAVAL STORES

No great advance has been made in this line, but conditions are improving and the principal reason back of this statement is the active return of foreign interests, especially England, into this market. The local situation has not improved to any extent, as difficulty is still being met in making shipments from the South. *Turpentine* held firm at the former \$1.49 level, with practically no business reported.

OILS

The bottom having been reached, it is now supposed that there will be a general tightening up, especially in *cottonseed* and *linseed* and a gradual return to the normal conditions. *Soya bean*, f.o.b. N. Y., and *peanut oil* crude seem to bear this statement out, as the former is being held firmly

at 14@14½c. and the latter at 17@18c. per lb. *Chinawood*, in bbl., f.o.b. Pacific Coast, is also stronger at 15½@16c. per lb. than it was last week and it is predicted by some and hoped for by all that these facts, combined with the fact that crushers have arrived at the point where they cannot go any lower, indicate increased activity.

The Chicago Market

Chicago, Ill., September 15, 1920.

All lines of the chemical trade in this market show steady quotations, in spite of which the market must be termed uncertain. In general, there is a feeling of nervousness, holders of stock not appearing anxious to dispose of commodities on a weak market and consumers being wholly unwilling to pay the quoted prices in the face of possibilities.

HEAVY CHEMICALS

The heavy chemical line shows nothing of interest. Producers of alkalis have not yet made public their price ideas for next season and trading is at a minimum pending this announcement. The same prices that have been quoted for the past month are still in effect, but actual buying is so slight as to render them practically nominal. It is felt that many of the few transactions going on are closed with the seller shading the price fractionally. *Alcohol* and *formaldehyde* are unchanged in price but, regardless of difficulty in securing goods, demand is weak. *Mercury* has kept pace here with the sharp reduction noted on both coasts, and is obtainable for \$78 per flask. Producers' prices on chlorine, based on 9½c. factory, are firmly held, with considerable business being done.

COAL-TAR PRODUCTS

Coal-tar products show a continuation of the lethargy which has enveloped them for many weeks. The recent partial shutdown in the textile industry deprived the line of its last vestige of life and it is surprising only that demoralization was not the result. All things considered, prices have held up remarkably well and with the gradual resumption of the textile mills, which even now is beginning, things should brighten up. The past seven-day period has seen no price changes of moment and few deals.

FERTILIZERS

Fertilizers are likewise weak. Unusually heavy fall rains have retarded agricultural operations, thus delaying consumers' buying of fertilizer materials. As between the producer and dealer, a disposition for watchful waiting is shown. Considerable finished product is accumulating in makers' hands, but no interesting price changes are reported.

NAVAL STORES

Indications are that price recessions in naval stores have reached their limit, at least for a time. Reports from the South are to the effect that export bidding is taking a share in stabilizing prices and locally demand is keeping even pace with supply. *Turpentine* shows a shade more strength, the current price in barrels, less than carlots, being \$1.52 per gal. Jobbers are quoting to the consuming trade, in small lots, \$1.75, but it is doubtful if this price is being adhered to rigidly. *Rosin* also show strength, quotations being ½ to 1c. higher, and all grades going at the same price. It is understood this item is particularly affected by export demand. *Pine oil*, in slightly better supply, is still quickly absorbed at the prevailing high prices by hungry consumers.

VEGETABLE OILS

There is a point in the price trend of all commodities which, when reached, will induce buying almost regardless of surrounding conditions. This same point seems to have been reached in the trading in vegetable oils. With indications of enormous supplies practically unchanged, prices showed a decided resistance to further hammering and considerable trading was indulged in, largely by the speculative element, as consumers still seem disposed to hold aloof.

A falling off in the estimated coming crop of flaxseed has caused plenty of bull talk in *linseed oil*, but the market failed to react. Tanks, for prompt and immediate delivery, f.o.b. Chicago, are quoted at \$1.15 per gal., with post-September deliveries at \$1.06@1.07. In barrels 7c. is added. Jobbers' printed quotation to consumers in less than 5 bbl. is \$1.45, but bona fide orders probably find a slightly lower level. There seems to be nothing in the flax outlook that points to higher prices.

Corn oil, at the current quotation of 8½@9c. per lb., created wide interest, the price being low enough to cause buyers to come out of retreat. The slightest indication of an advance above 9c. was sufficient to stop trading, however, and that level seem fixed as the maximum for some days. Actual quotations on *cottonseed oil* show no change, prime summer yellow being quoted at 12½c. lb. in tanks, Chicago, and refined at 16½c. The consumer is remaining out of the market at these figures, even though the southern planters are protesting that the price is dangerously low.

Oriental oils remain quiet. *Coconut oil* is quoted at the coast in seller's tanks at 13½@13¾c., current local price in barrels being 16@16½c. Transactions are few. *Soya bean oil* is held for 9@9½c. for prompt coast shipment, buyers' lack of response indicating that the consumer thinks it is still too high. *Chinawood oil* finds light demand at the f.o.b. Chicago price of 16½@16¾c., and *red oil* reflects the partial paralysis of the textile trade by registering no business on the low basis of 13c. per lb., Chicago, in tank cars.

The St. Louis Market

St. Louis, Mo., September 14, 1920.

The chemical market in this district has been quiet for the last month, there having been a slight easing-off of business over that of a month ago. Producers assert, however, that there is enough business to permit them to dispose of their entire volume without any danger of bearing down the market and that inquiries are coming in in good volume. Orders are well divided between those for immediate delivery and those for 1921 delivery. Prices have made no change during the past month, quotations made then having included increased costs due to the freight rate raises.

CHEMICAL SUPPLY EQUAL TO DEMAND

The supply of chemicals on hand locally is, with the exception of *muratic acid*, amply sufficient to meet the demand, but no price trend downward is noticeable, and the following quotations, based on carlots unless otherwise noted, are holding firm. There is a fairly good demand for *sulphuric acid* with prices steady. The 60 deg. grade is quoted at \$16 per ton and 66 deg. at \$24 per ton. There is slightly better demand for *oleum*, which is still quoted at \$27.50 per ton.

SHORTAGE OF MURIATIC ACID

A considerable shortage of *muratic acid* has developed, but prices remain unchanged at \$25 per ton and 2 to 2½c. per lb. in carboys. The shortage is ascribed to the fact that there is a better demand now than there was a month ago and supplies from the East have been shut off.

Stocks of *sodium bisulphate* are good and prices remain the same, \$5 to \$6 a ton being quoted, depending on the size of the order.

Nitric acid is showing signs of activity, inquiries being good. It is quoted at \$7 per cwt. for the 36 deg. and \$10 per cwt. for the 42 deg. Standard mixed acid remains firm at 1½c. per lb. of sulphuric and 11½c. per lb. of nitric.

There is no change in the price of *zinc chloride*, which registered a 25c. increase some time ago. Producers think this price will remain stable for some time. It is being quoted at \$4 per cwt.

There are large stocks of *phenol* on hand, but the St. Louis firm which is disposing of the surplus Government supply is having no trouble keeping the market on it steady. It is being quoted at 12c. per lb. in lots of fifteen tons or more.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride..... lb.		\$0.65 - \$0.75

Oxalic, crystals..... lb.	.45 - .50	.52 - .55
Phosphoric, Ortho, 50 per cent solution..... lb.	.18 - .23	.24 - .25
Picric..... lb.	.28 - .35	.40 - .51
Pyrogallol, resublimed..... lb.	2.30 - 2.55	2.60 - 2.65
Sulphuric, 60 deg., tank cars..... ton	12.00 - 16.00	
Sulphuric, 60 deg., drums..... ton		
Sulphuric, 66 deg., tank cars..... ton	16.00 - 17.00	18.00 - 20.00
Sulphuric, 66 deg., drums..... ton	26.00 - 28.00	
Sulphuric, 66 deg., carboys..... ton		
Sulphuric, fuming, 20 per cent (oleum) tank cars..... ton	27.00 - 30.00	37.00 - 42.00
Sulphuric, fuming, 20 per cent (oleum) drums..... ton	28.00 - 30.00	38.00 - 42.00
Sulphuric, fuming, 20 per cent (oleum) carboys..... ton	32.00 - 35.00	40.00 -
Tannic, U. S. P..... lb.	1.45 - 1.50	1.55 - 1.65
Tannic (tech)..... lb.	.60 - .70	.80 - .90
Tartaric, crystals..... lb.		.74 - .77
Tungstic, per lb. of WO..... lb.		1.20 - 1.40
Alcohol, Ethyl (nominal)..... gal.	5.50 - 5.75	6.00 - 7.00
Alcohol, Methyl (see methanol)..... gal.		
Alcohol, denatured, 188 proof (nominal)..... gal.		1.12 - 1.15
Alcohol, denatured, 190 proof (nominal)..... gal.		1.05 - 1.10
Alum, ammonia lump..... lb.	.05 - .05½	.05½ - .06
Alum, potash lump..... lb.	.08 - .08½	.09 - .09½
Alum, chrome lump..... lb.		.18 - .19
Aluminium sulphate, commercial..... lb.	.04 -	
Aluminium sulphate, iron free..... lb.	.06 -	
Aqua ammonia, 26 deg., drums (750 lb.)..... lb.	.09 - .10	.11 - .12
Ammonia, anhydrous, cylinders (100-150 lb.)..... lb.	.35 - .35½	.35 - .37
Ammonium carbonate, powder..... lb.	.16 - .16½	.17 - .18
Ammonium chloride, granular (white sal ammoniac) (nominal)..... lb.	.15 - .16	.17 - .18
Ammonium chloride, granular (gray sal ammoniac)..... lb.	.13 - .13½	.13½ - .14
Ammonium nitrate..... lb.	.09 - .10	.11 - .14
Ammonium sulphate..... lb.	.07 - .07½	.08 -
Amylacetate..... gal.		5.00 -
Amylacetate tech..... gal.		4.75 - 5.25
Arsenic, oxide, lumps (white arsenic)..... lb.	.14 - .16	.16 - .17
Arsenic, sulphide, powdered (red arsenic)..... lb.	.17 - .18	.19 - .23
Barium chloride..... ton	130.00 - 150.00	
Barium dioxide (peroxide)..... lb.	.21 - .23	.24 - .25
Barium nitrate..... lb.	.10 - .12	.12 - .13½
Barium sulphate (precip.) (blanc fixe)..... lb.	.04 - .05	.05½ - .06
Bleaching powder (see calcium hypochlorite).....		
Blue vitriol (see copper sulphate).....		
Borax (see sodium borate).....		
Bromine..... lb.	.70 - .90	1.00 - 1.05
Bromine..... cwt.	3.50 - 3.55	
Calcium acetate..... cwt.	.04 - .04½	.04½ - .05½
Calcium carbide..... lb.	.04 - .04½	
Calcium chloride, fused, lump..... ton	33.00 - 34.00	35.00 - 45.00
Calcium chloride, granulated..... lb.	.02 - .02½	.03 - .03½
Calcium hypochlorite (bleaching powder)..... cwt.	7.00 - 7.50	8.00 - 8.50
Calcium peroxide..... lb.		1.50 - 1.70
Calcium phosphate, monobasic..... lb.		.75 - .80
Calcium sulphate, pure..... lb.		.25 - .30
Carbon bisulphide..... lb.	.08 - .09	.10 - .11
Carbon tetrachloride, drums..... lb.	.14 - .15	.16 - .17
Carbonyl chloride (phosgene)..... lb.		
Caustic potash (see potassium hydroxide).....		
Caustic soda (see sodium hydroxide).....		
Chlorine, gas, liquid-cylinders (100 lb.)..... lb.	.09 - .09½	.10 - .10½
Chloroform..... lb.	.40 - .43	.44 - .47
Cobalt oxide..... lb.		2.05 - 2.05
Copperas (see iron sulphate).....		
Copper carbonate, green precipitate..... lb.	.27 - .28	.29 - .31
Copper cyanide..... lb.		.65 - .70
Copper sulphate, crystals..... lb.	.08 - .09	.09 - .09½
Copper of tartar (see potassium bitartrate).....		
Cream salt (see magnesium sulphate).....		
Ethyl Acetate Com. 85%..... gal.	1.10 - 1.30	1.40 -
Ethyl Acetate pure (acetic ether 98% to 100%)..... lb.		1.75 -
Formaldehyde, 40 per cent (nominal)..... lb.	.48 - .50	
Fusel oil, ref..... gal.		5.25 - 6.00
Fusel oil, crude (nominal)..... gal.		
Glauber's salt (see sodium sulphate).....		
Glycerine, C. P. drums extra..... lb.		.26 - .28
Iodine, resublimed..... lb.	4.30 - 4.35	4.40 - 4.45
Iron oxide, red..... lb.		.03 - .20
Iron sulphate (copperas)..... cwt.	2.00 - 2.25	2.35 - 2.75
Lead acetate, normal..... lb.		.13 - .16
Lead arsenate (paste)..... lb.	.11 - .12	.13 - .17
Lead nitrate, crystals..... lb.		.90 - 1.00
Litharge..... lb.	.14 - .15	.15 - .16
Lithium carbonate..... lb.		1.50 -
Magnesium carbonate, technical..... lb.	.12 - .13	.15 - .16
Magnesium sulphate, U. S. P..... 100 lb.	3.50 - 3.90	4.00 - 4.50
Magnesium sulphate, commercial..... 100 lb.		3.50 - 3.60
Methanol, 99%..... gal.		3.25 - 3.30
Methanol, pure..... gal.		3.50 - 4.50
Nickel salt, double..... lb.		.14 - .16
Nickel salt, single..... lb.		.13 - .14
Phosgene (see carbonyl chloride).....		1.25 - 1.50
Phosphorus, red..... lb.	.50 - .55	.60 - .65
Phosphorus, yellow..... lb.		.35 - .37
Potassium bichromate..... lb.	.33 - .36	.39 - .40

	Carlots	Less Carlots
Potassium bitartrate (cream of Tartar) . . . lb.	\$0 52 - \$0 56	\$0 57 - \$0 58
Potassium bromide, granular . . . lb.	70 - 73	70 - 73
Potassium carbonate, U. S. P. . . lb.	50 - 55	56 - 60
Potassium carbonate, crude . . . lb.	20 - 21	23 - 25
Potassium chlorate, crystals . . . lb.	18 - 18 1/2	19 - 20
Potassium hydroxide (caustic potash) . . lb.	27 - 28	29 - 33
Potassium iodide . . . lb.	17 - 17 1/2	19 - 21
Potassium nitrate . . . lb.	75 - 80	85 - 95
Potassium permanganate . . . lb.	85 - 95	1.00 - 1.05
Potassium prussiate, red . . . lb.	32 - 36	35 - 40
Potassium prussiate, yellow . . . lb.	32 - 36	35 - 40
Potassium sulphate (powdered) . . . ton	\$240.00 - 255.00	
Rochelle salts (see sodium potas. tartrate)		
Salammoniac (see ammonium chloride)		
Salt soda (see sodium carbonate)		
Salt cake . . . ton		48.00 - 50.00
Silver cyanide (nominal) . . . oz.		1.25 - 1.50
Silver nitrate (nominal) . . . oz.		3.60 - 3.50
Soda ash, light . . . 100 lb.		3.20 - 3.50
Soda ash, dense . . . 100 lb.		3.55 - 3.65
Sodium acetate . . . lb.	10 - 15	20 - 25
Sodium bicarbonate . . . 100 lb.	2.50 - 2.75	3.00 - 3.50
Sodium bichromate . . . lb.	22 - 24	26 - 27
Sodium bisulphate (nitre cake) . . . ton	7.00 - 8.00	9.00 - 11.00
Sodium bisulphate Powdered, U.S.P. . lb.	08 - 10	10 - 11
Sodium borate (borax) . . . lb.	09 - 10	11 - 12
Sodium carbonate (sal soda) . . . 100 lb.	2.10 - 2.10	2.15 - 2.25
Sodium chloride . . . lb.	11 - 12	12 - 14
Sodium cyanide, 96-98 per cent. . . lb.	25 - 30	32 - 35
Sodium fluoride . . . lb.	18 - 19	19 - 20
Sodium hydroxide (caustic soda) . . . 100 lb.	5.60 - 5.70	5.75 - 6.00
Sodium hypsulphite . . . lb.		03 - 04
Sodium molybdate . . . lb.	2.50 - 3.00	3.25 - 4.00
Sodium nitrate . . . 100 lb.	3.00 - 3.25	3.75 - 4.00
Sodium nitrite . . . lb.	16 - 18	19 - 20
Sodium peroxide, powdered . . . lb.	32 - 35	35 - 40
Sodium phosphate, dibasic . . . lb.	03 1/2 - 04 1/2	04 - 05
Sodium potassium tartrate (Rochelle salts) lb.	23 - 27	31 - 32
Sodium prussiate, yellow . . . lb.	01 1/2 - 01 1/2	02 - 02 1/2
Sodium silicate, solution (40 deg.) . . lb.	02 1/2 - 03	04 - 05
Sodium silicate, solution (60 deg.) . . lb.	02 1/2 - 03	04 - 05
Sodium sulphate, crystals (Glauber's salt) cwt	1.60 - 1.70	1.75 - 2.50
Sodium sulphide, crystal, 60-62 percent (cone) lb.	09 - 10	10 - 11
Sodium sulphite, crystals . . . lb.	04 - 04 1/2	05 - 05
Sroutium nitrate, powdered . . . lb.	15 - 18	19 - 20
Sulphur chloride red . . . lb.	08 - 09	10 - 10
Sulphur, crude . . . ton	16.00 - 20.00	
Sulphur dioxide, liquid, cylinders . . lb.	09 - 10	10 - 12
Sulphur (sublimed), flour . . . 100 lb.		3.80 - 4.35
Sulphur, roll (brimstone) . . . 100 lb.		3.40 - 3.90
Tin bichloride (stannous) . . . lb.	42 1/2 - 44	45 - 46
Tin oxide . . . lb.		55 - 65
Zinc carbonate, precipitate . . . lb.	16 - 18	19 - 20
Zinc chloride, gran. . . lb.	13 - 13 1/2	13 1/2 - 17
Zinc cyanide . . . lb.	45 - 49	50 - 60
Zinc dust . . . lb.	12 - 13	13 - 14
Zinc oxide, U. S. P. . . lb.	17 - 25	
Zinc sulphate . . . lb.	03 1/2 - 03 1/2	04 - 06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude . . . lb.	\$1 40	\$1 50
Alpha naphthol, refined . . . lb.	1.60	1.70
Alpha-naphthylamine . . . lb.	30	33
Aniline oil, drums extra . . . lb.	35	40
Aniline salts . . . lb.	90	1.00
Anthracene, 80% in drums (100 lb.) . lb.	2.00	2.10
Benzaldehyde (f.f.e.) . . . lb.	1.35	1.40
Benzidine, base . . . lb.	1.15	1.25
Benzidine sulphate . . . lb.		90
Benzoic acid, U. S. P. . . lb.	80	90
Benzoate of soda, U. S. P. . . lb.	38	40
Benzene, pure, water-white, in drums (100 gal) . gal	36 1/2	38
Benzene, 90% in drums (100 gal) . . gal	35	40
Benzyl chloride, 95-97%, refined . . lb.	25	35
Benzyl chloride, tech. . . lb.	3.50	4.00
Beta-naphthol benzoate (nominal) . . lb.	.80	.85
Beta-naphthol, sublimed (nominal) . . lb.	2.25	2.40
Beta-naphthol, tech (nominal) . . . lb.	18	19
Beta-naphthylamine, sublimed . . . lb.	23	25
Cresol, U. S. P., in drums (100 lb.) . lb.	1.15	1.20
Ortho-cresol, in drums (100 lb.) . . lb.	1.05	1.10
Cresylic acid, 97-99%, straw color, in drums . gal	1.05	1.10
Cresylic acid, 95-97%, dark, in drums . gal	.65	.75
Cresylic acid, 50%, first quality, drums . gal	.08	.10
Dichlorobenzene . . . lb.	1.50	1.60
Diethylaniline . . . lb.	.95	1.05
Dimethylaniline . . . lb.	30	37
Dinitrobenzene . . . lb.	32	35
Dinitrochlorobenzene . . . lb.	45	55
Dinitronaphthalene . . . lb.	40	45
Dinitrophenol . . . lb.	40	40
Dinitrotoluene . . . lb.	38	40
Dip oil, 25%, tar acids, car lots, in drums . gal	1.80	.85
Diphenylamine (nominal) . . . lb.	1.90	2.05
H-acid (nominal) . . . lb.	1.25	1.30
Meta-phenylenediamine . . . lb.	18	20
Monochlorobenzene . . . lb.	2.00	2.40
Monothylaniline . . . lb.		14 1/2
Naphthalene crushed, in bbls. (250 lb.) . lb.	15	17
Naphthalene, flake . . . lb.	.75	.85
Naphthalene, balls . . . lb.	14	19
Naphthionic acid, crude . . . lb.	40	50
Nitrobenzene . . . lb.	18	25
Nitronaphthalene . . . lb.	3.25	4.25
Nitro-toluene . . . lb.	15	20
Ortho-amidophenol . . . lb.	.80	.85
Ortho-dichlorobenzene . . . lb.	.25	.40
Ortho-nitro-phenol . . . lb.	.30	.35
Ortho-nitro-toluene . . . lb.	2.50	3.00
Ortho-toluidine . . . lb.	2.50	3.00
Para-amidophenol, base . . . lb.	.08	.12
Para-amidophenol, HCl . . . lb.	1.10	1.15
Para-dichlorobenzene . . . lb.		
Paranitroaniline . . . lb.		

Para-nitrotoluene . . . lb.	.35	
Para-phenylenediamine . . . lb.	.50	
Para-toluidine . . . lb.	.00	2.25
Phthalic anhydride . . . lb.	.60	.70
Phenol, U. S. P., drums (dest.), (240 lb.) . lb.	.12	.20
Pyridine . . . gal	.00	3.50
Resorcinol, technical . . . lb.	.25	4.50
Resorcinol, pure . . . lb.	.25	6.75
Salicylic acid, tech., in bbls (110 lb.) . lb.	.50	.52
Salicylic acid, U. S. P. . . lb.	.50	.60
Salol . . . lb.	.90	.00
Solvent naphtha, water-white, in drums, 100 gal . gal	.13	.15
Solvent naphtha, crude, heavy, in drums, 100 gal . gal	.25	.26
Sulphanilic acid, crude . . . lb.	.42	.35
Toluidine . . . lb.	.70	2.50
Toluidine, mixed . . . lb.	.45	.55
Toluene, in tank cars . . . gal.	.45	
Toluene, in drums . . . gal	.48	.40
Xylidines, drums, 100 gal . . . lb.	.50	.65
Xylene, pure, in drums . . . gal	.47	.50
Xylene, pure, in tank cars . . . gal	.45	
Xylene, commercial, in drums, 100 gal . gal	.42	.35
Xylene, commercial, in tank cars . . . gal.	.40	

Waxes

Prices based on original packages in large quantities

Beeswax, refined, dark . . . lb.	\$0 36	\$0 39
Beeswax, refined, light . . . lb.	.37	.38
Beeswax, white pure . . . lb.	.43	.68
Carnauba, No. 1 (nominal) . . . lb.	.90	.95
Carnauba, No. 2, regular (nominal) . . lb.	.85	.86
Carnauba, No. 3, North Country . . . lb.	.35	.36
Japan . . . lb.	.17	.18
Mountain, crude . . . lb.	.25	.26
Paraffine waxes, crude match wax (white) 105-110 m.p. . . lb.	.09	.09 1/2
Paraffine waxes, crude, scale 124-126 m.p. . lb.	.09 1/2	.11
Paraffine waxes, refined, 118-120 m.p. . . lb.	.11	.11 1/2
Paraffine waxes, refined, 125 m.p. . . lb.	.12	
Paraffine waxes, refined, 128-130 m.p. . lb.	.13	.15
Paraffine waxes, refined, 133-135 m.p. . lb.	.16	.17
Paraffine waxes, refined, 135-137 m.p. . lb.	.17 1/2	.18 1/2
Stearic acid, single pressed . . . lb.	.20	.21
Stearic acid, double pressed . . . lb.	.22	.23
Stearic acid, triple pressed . . . lb.	.24	.25

NOTE—Paraffine waxes very scarce

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940 . . . gal	\$2.15	
Pine oil, pure, dest. dist. gal	1.80	
Pine tar oil, ref., sp. gr. 1.025-1.035 . . . gal	.48	
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla . gal	.35	
Pine tar oil, double ref., sp. gr. 0.965-0.990 . . gal	.85	
Pine tar, ref., thin, sp. gr. 1.080-1.060 . . . gal	.36	
Turpentine, crude, sp. gr. 0.900-0.970 . . . gal	1.75	
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990 . gal	.35	
Pinewood creosote, ref. gal	.52	

Naval Stores

The following prices are f.o.b., New York, for carload lots:

Rosin (H-I), bbl . . . 280 lb.	\$14 60	
Rosin (K-L) . . . 280 lb.	14 50	
Rosin (M-N) . . . 280 lb.	14 50	
Rosin W. (G-W) . . . 280 lb.	14 50	
Wood rosin, bbl. . . 280 lb.	15 00	
Spirits of turpentine . . . gal	1.49	
Wood turpentine, steam dist. . . gal		
Wood turpentine, dest. dist. . . gal		
Pine tar pitch, bbl . . . 200 lb.		8 50
Pine, kiln burned, bbl. (500 lb.) . . . bbl	14 50	15 00
Retort tar, bbl . . . 500 lb.	15 00	15 50
Rosin oil, first run . . . gal	72	
Rosin oil, second run . . . gal		
Rosin oil, third run . . . gal		

Solvents

75-76 deg., steel bbls. (85 lb.) gal	\$0.40	
70-72 deg., steel bbls. (85 lb.) gal	.38	
68-70 deg., steel bbls. (85 lb.) gal	.37	
V. M. and P. naphtha, steel bbls. (85 lb.) . gal	.29	

Crude Rubber

Para—Upriver fine . . . lb.	\$0.29	\$0.91
Upriver coarse . . . lb.	.19	.20
Upriver caucho ball . . . lb.	.20	.22
Plantation—First latex crepe . . . lb.	.30	
Ribbed smoked sheets . . . lb.	.28	
Brown crepe, thin, clean . . . lb.	.26	
Amber crepe No. 1 . . . lb.	.28	

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots

Castor oil, No. 3, in bbls lb.		\$0 18
Castor oil, AA, in bbls lb.		
China wood oil, in bbls (f.o.b. Yue coast) . . lb.	.15 1/2	.16
Cocanut oil, Ceylon grade, in bbls . . . lb.	.15	.16
Cocanut oil, Ceylon grade, in bbls (nominal) . lb.	.16	.17 1/2
Cora oil, crude, in bbls . . . lb.	.11 1/2	.13
Cottonseed oil, crude (f.o.b. mill) . . . lb.	.10	.11
Cottonseed oil, summer yellow . . . lb.	.14	.15
Cottonseed oil, winter yellow . . . lb.	.17 1/2	.18 1/2
Lined oil, raw, car lots (domestic) . . . gal	1.25	
Lined oil, raw, tank cars (domestic) . . . gal	1.22	
Lined oil, boiled, car lots (domestic) . . . gal	1.35	

Olive oil, commercial.....	gal.	3.00	—	3.50
Palm, Lagos.....	lb.	.10	—	.10
Palm, bright red.....	lb.	.10	—	.10
Palm, Niger.....	lb.	.10	—	.10
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.10	—	.10
Peanut oil, refined, in bbls.....	lb.	.17	—	.18
Rapeseed oil, refined in bbls.....	gal.	1.40	—	1.50
Rapeseed oil, blown, in bbls.....	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls N. Y.....	lb.	.14	—	.14
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.09	—	.11

FISH

Winter pressed Menhaden.....	gal.	\$0.90	—	\$1.05
Yellow bleached Menhaden.....	gal.	0.95	—	1.05
White bleached Menhaden.....	gal.	1.00	—	1.25
Blown Menhaden.....	gal.	1.00	—	1.20

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$22.00	—	\$25.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	18.00	—	20.00
Barytes, crude, 88% (a. 94%), ba., Kings Creek	net ton	8.00	—	10.00
Barytes, ground, white, f.o.b. Cartersville, Ga.	net ton	23.00	—	25.00
Barytes, ground, off color, f.o.b. Cartersville	net ton	16.00	—	19.00
Barytes, crude, 88% (a. 94%), ba., Cartersville	net ton	12.00	—	—
Barytes, floated, f.o.b. St. Louis	net ton	26.50	—	28.00
Barytes, crude, min. 98% ba., Missouri	net ton	11.00	—	11.25
Blanc fixe, dry.....	lb.	.05	—	.06
Blanc fixe, pulp.....	net ton	60.00	—	80.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Colorado

DENVER—The Eaton Metal Products Co., 1843 Mazoe St., is having plans prepared for the construction of a 1 story steel products manufacturing plant on York St. near the Union Pacific shops. Estimated cost, \$175,000.

DENVER—The Federal Glass Co., 1717 Champa St., is having plans prepared for the construction of a glass factory. Estimated cost, \$250,000. J. W. Husard, c/o Sylvester & Co., 1717 Champa St., engr. Noted Sept. 1.

DENVER—The Great Valleys Sugar Corp., 800 Central Savings Bank Bldg., is having preliminary plans prepared for the construction of 3 complete sugar factories. Estimated cost, \$3,000,000. A. F. Lyster, engr.

LA SALLE—The Industrial Sugar Co., Barclay Block, Denver, has awarded the contract for the construction of a sugar factory, consisting of several buildings, to Baum & Baum, Salt Lake City, Utah. Estimated cost, \$1,800,000.

Connecticut

ANSONIA—The Amer. Brass Co., 58 Liberty St., plans to build several large additions to its plant on Bridge St.

Illinois

DE KALB—Rev. J. A. Solon plans to build a 3-story, 40x178-ft. hospital. A chemical laboratory will be installed in same. Estimated cost, \$150,000. Arthur Foster, 1555 North Clark St., archt.

Indiana

TERRE HAUTE—The Hoosier Rolling Mills Co. will build a 1-story, 100x600-ft. factory. Estimated cost, \$100,000. Work will be done by day labor.

Iowa

MALLARD—The City Clerk will soon receive bids for the construction of a sewage disposal plant, sand filter and sludge beds. Estimated cost, \$50,000. E. T. Archer & Co., New England Bldg., Kansas City, Mo., engr.

NEW MARKET—The City Clerk will soon award the contract for the installation of a septic tank and sludge bed. Estimated cost, \$84,000. E. T. Archer & Co., New England Bldg., Kansas City, Mo., engr.

Maine

HOWLAND—The Howland Pulp & Paper Co., 301 Congress St., has awarded the contract for the construction of a 38x72-ft. addition to paper machine building and a 75x103-ft. addition to sulphate pulp mill to Green & Wilson, Waterville. Estimated cost, \$120,000.

Maryland

BALTIMORE—The Baltimore Malleable Iron & Steel Castings Co., Charles and Wells Sts., plans to install additional blast furnaces and other equipment. Estimated cost, \$100,000.

CANTON (Baltimore P. O.)—The Standard Oil Co., Pratt and South Sts., plans to build an oil refinery here. Estimated cost, \$7,000,000. E. A. Holbein, supt.

SPARROWS POINT—J. E. Sperry, archt., 409 Calvert Bldg., Baltimore, will soon award the contract for the construction of a 3-story hospital for the Bethlehem Steel Corp. A laboratory including equipment will be installed in same. Estimated cost, \$150,000.

Massachusetts

PALMER—The Palmer Fdry. & Machine Co., 27 Foundry St., has awarded the contract for the construction of a 1-story foundry to the Flynt Bldg. & Constr. Co., 356 Main St. Estimated cost, \$20,000.

RUSSELL—The Chapin & Gould Paper Co., 317 Main St., Springfield, has awarded the contract for the construction of a 4-story paper factory to F. T. Ley & Co., Inc., 499 Main St., Springfield. Estimated cost, \$100,000.

WORCESTER—Holy Cross College, College St., plans to build 5 buildings including a science hall, etc. Estimated cost, \$1,000,000.

Michigan

DETRAY (Detroit P. O.)—The Inland Detray Salt Co. will soon award the contract for the construction of a 2-story, 140x170-ft. factory. Estimated cost, \$60,000. Stahl & Kinsey, 435 Woodward Ave., Detroit, archts.

MONROE—Reed M. Dunbar, archt., will soon award the contract for the construction of a 1-story, 90x210-ft. foundry on East 1st St. for the Monroe Auto Equipment Co., East 1st St. Estimated cost, \$100,000. Noted Sept. 15.

New Hampshire

GROVETON—The Groveton Paper Co., Inc., has awarded the contract for the construction of a 2-story, 65x200-ft. paper factory to Swan & Son, St. Johnsbury, Vt. Estimated cost, \$100,000.

New Jersey

BRIDGETON—The Illinois Glass Co. has awarded the contract for the construction of a glass factory including a 3-story, 330x700-ft. main plant and two 50x150-ft. units, etc., to the Keeley Bros. Constr. Co., 507 Federal St., Camden. Estimated cost, \$3,000,000. Noted Sept. 15.

LIGHTSTOWN—The Borough has awarded the contract for filtration plant equipment including 2 horizontal steel pressure filters to the New York Continental Jewel Filtration Co., Flatiron Bldg., New York City. Estimated cost, \$8,000.

NEWARK—The George LaCombe Co. plans to build a 75x140-ft. factory for the manufacture of concrete blocks on Victoria St. Estimated cost, \$25,000. Fred Noble, engr.

New York

RIKERS ISLAND—The Dept. of Correction received bids for the installation of sterilizing and disinfection machines at the farm here from Kny-Scheerer Co., 56 West 23rd St., New York City, \$1,770; Cromwell Dean Co., \$1,779.

Ohio

ALLIANCE—The Alliance Brick Co. is building a plant and is in the market for brick-making machinery.

CANTON—The United Eng. & Fdry. Co., 13th St., N.E., has awarded the contract for the construction of a 1-story, 136x240-ft. factory on Grace Ave., N.E., and 13th St., N.E., to R. G. Whittier, 1539 Howard Court, N.W. Estimated cost, \$75,000.

LONDON—The Williams Mfg. Co. has awarded the contract for the construction of a 1-story, 50x180-ft. factory to W. H. Robbins, Springfield. Estimated cost, \$45,000.

TOLEDO—The Acklin Stamping Co., Dorr St., has purchased a site on Nebraska Ave. near the Lake Shore Crossing and plans to build a large factory on same. Annealing furnaces, nickel plating and galvanizing plants, electric welding and tool departments will be installed in same. D. T. Anderson, supt.

Pennsylvania

AVONDALE—The Consolidated Bd. of New Gordon and Loudin Grove Townships

in West Grove and Avondale Boroughs, Chester Co., plans to build a 2-story high school here. A chemical laboratory will be installed in same. Estimated cost, \$100,000. Rittler & Shay, North Amer. Bldg., Philadelphia, archts.

Texas

WICHITA FALLS—The State Bd. of Control, Austin, will receive bids until Oct. 4 for the construction of a sewage disposal plant, etc., at the Northwest Texas Insane Asylum here.

Vermont

NORTHFIELD—H. Pelaggi & Co. will build a 1-story, 60x425-ft. plant addition. Estimated cost, \$50,000. Work will be done by day labor.

Wisconsin

MERTON—The Merton Dairy Products Co. has awarded the contract for the construction of a 1-story, 30x45-ft. addition to its creamery to Reisinger & Co., 425 East Water St., Milwaukee. A chemical laboratory will be installed in same. Estimated cost, \$18,000. Noted July 28.

Quebec

MONTREAL—The L'air Liquide Society, Maisonneuve, plans to build extensions to its welding and cutting plants.

MONTREAL—The Natl. Drug & Chemical Co., 34 St. Paul St., has awarded the contract for the construction of a factory to Church, Ross & Co., 10 Cathcart St. Estimated cost, \$75,000. Noted June 23.

Ontario

AGATE—S. Bromley, Pembroke, representing owners, plans to build a pulp and paper mill here. Estimated cost, \$500,000.

PETROLEA—E. A. Stokes plans to build a plant for the manufacture of nitroglycerine and is in the market for machinery and equipment for same. Estimated cost, \$100,000.

Manufacturers' Catalogs

THE READING IRON PIPE CO., Reading, Pa., has issued Bull. No. 1, entitled "Reading Wrought Iron Pipe." It is a very instructive booklet and gives in thirty-two pages very interesting descriptions of the origin and development of the wrought iron industry, the puddling process, the manufacture of skelp, why wrought iron is better for making welded pipe than steel, Reading iron pipes in oil country service, building service, refrigerating service, coal mine service, and charcoal iron boiler tubes for locomotive, marine and stationary boilers, together with appropriate illustrations.

THE JEFFREY MANUFACTURING CO., Columbus, O., has issued two new catalogs. No. 312 is entitled "Jeffrey Storage Battery Locomotives for Mines." Particular attention is called in this catalog to the Jeffrey pivoted battery box, which makes motors accessible for inspection and oiling without having to remove the battery box, also allows removing and replacing of the pinions on the armature shaft without having to run the locomotive under a crane or over a pit. It fully illustrates and describes other important features of Jeffrey storage battery locomotives for mining service, including motor equipment, new style journal box for inside wheel type locomotive, etc., and also contains illustrative photographs of electric gathering locomotives of the Standard cable reel and crab reel types. Catalog No. 263 is entitled "Jeffrey Mine Locomotives." This catalog fully illustrates and describes the electrical and mechanical features of this company's complete line of mine locomotives, including the "Armorplate" type of main haulage locomotive, and electric gathering locomotives of the cable reel, crab reel, combination cable and crab reel, and electric storage battery types. Both of these catalogs are interesting and contain many illustrations.

VACUUM OIL CO., New York, has published a 32-page booklet on Bearings and Their Lubrication. The construction, types and materials used in bearings are briefly outlined. Oiling systems, distribution and lubrication are discussed. Oils and greases are described relative to their application.

THE PERMUTT CO., New York, announces the publication of Bull. No. 101, which covers the various products manufactured by the company. This attractive 32-page catalog contains a brief discussion of water rectification or conditioning problems, and the solution by the complete line of apparatus manufactured by the Permutt Co., such as softeners, filters, iron and manganese removal equipment, etc., although it is not an attempt to cover the vast field, but serves principally to indicate the problems which have been met and solved by its technical staff. Many interesting illustrations are given, together with descriptive matter.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN ENGINEERING COUNCIL of the Federated American Engineering Societies will hold a meeting Nov. 18 and 19, 1920, in Washington, D. C. Headquarters will be at the New Willard Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1920 convention and exhibit at Columbus, Ohio, the week of Oct. 4.

A.I.M.E. PETROLEUM AND GAS MEETING is being held in St. Louis, Mo., Sept. 21 and 22, in conjunction with the American Society for Testing Materials and the Petroleum Fuel Section of the A.S.M.E. It is expected that this meeting will crystallize into a petroleum and gas section of the A.I.M.E.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1920 annual meeting will be held in the Engineering Societies' Building, from Dec. 7 to 10 inclusive.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS is holding its 14th annual convention at the Hotel Pennsylvania, New York City, Sept. 20 to 24.

CANADIAN INSTITUTE OF MINING AND METALLURGY will hold its second annual Western meeting in Winnipeg, Man., on Oct. 25, 26 and 27. Headquarters will be at the Hotel Fort Garry.

THE CHEMICAL WARFARE POST of the American Legion will hold its next meeting Sept. 22, at 8 p.m., in the conference room of the Grand Central Palace, New York City.

ELECTRIC FURNACE ASSOCIATION will hold a meeting Oct. 6, at Columbus, Ohio, the subject of which will be "Refractories."

ENGINEERING COUNCIL will hold its next meeting in Chicago Thursday, Oct. 21.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

NATIONAL ASSOCIATION OF PURCHASING AGENTS will hold its annual convention at the Congress Hotel, Chicago, Ill., Oct. 11, 12 and 13.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SIXTH) is being held in the Grand Central Palace, New York City, Sept. 20 to 22.

THE RUBBER SECTION of the National Safety Council will consider safety problems of especial interest to the rubber industry at a section conference to be held Sept. 29 to Oct. 1, in connection with the national session of the Council to be held in Chicago.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12.

Industrial Notes

UEHLING INSTRUMENT CO., New York City, manufacturer of fuel economy equipment, announces that it is now being represented in the New England States by the Smith Engineering & Supply Co., 89 State St., Boston, Mass., manufacturers' agent and engineer, specializing in power plant equipment. S. W. Smith, president of the latter company, was until very recently associated with the Uehling Instrument Co. with headquarters in the New York office.

C. M. TRATS, formerly secretary of the Oklahoma Brick Manufacturers Association, has moved to Memphis, Tenn., where he will be local manager for the Reliance Brick Co., manufacturer of building and enameled brick, hollow tile, etc.

THE INDUSTRIAL DEVELOPMENT COMMITTEE of the Oklahoma Chamber of Commerce is planning a survey of the industries of that territory. The work is divided into various sections, such as banking, labor conditions, transportation, agriculture, oil, tax, living conditions, business utilities, etc. Increased production of mining and manufacturing has made the inauguration of a comprehensive study necessary.

THE PORTER POTTERY CO., INC., of Clinton Ky., has established a branch office in the McCall Bldg., at Memphis, Tenn.

THE SAMSON MOTOR TRUCK CO., of Janesville, Wis., a division of the General Motors Corp., has established a branch at 228 Monroe Ave., Memphis, Tenn.

A. LUSSKIN & CO., New York City, announces that I. Miller of its staff sailed on the Adriatic, Aug. 14, for an extended trip through Europe, in connection with the purchase and sale of chemicals, colors, oils and waxes.

THE VOOLRATH CO., of Sheboygan, Wis., manufacturer of enameled ware, has secured a building for the installation of a plant at 821 West Lake St., Chicago, Ill.

THE JEWELL POLAR CO., manufacturer of water stills, has purchased the 2-story factory at 565 West Van Buren St., Chicago.

QUIGLEY FURNACE SPECIALTIES CO., New York City, announces that the furnaces for the new sheet mill of Follansbee Bros. Co., Toronto, Ohio, will be fired with powdered coal. For transporting the pulverized fuel from the milling plant to the furnace bins, the Quigley air transport system has been adopted. A standard blowing unit of five tons capacity consisting of pulverized fuel bin, blow tank and scales, which is capable of transporting ten tons of pulverized coal per hour, will be installed. The total distance for transporting fuel is approximately 1,700 ft. This blowing equipment is being furnished by the Quigley Furnace Specialties Co.

EASTON CAR & CONSTRUCTION CO. announces the opening of a new office in the Peoples Gas Bldg., Chicago, to take care of the increasing business in the West and Middle West districts.

THE METAL & THERMIT CORP., New York City, has made arrangements to secure life insurance for all its employees who have served the company for at least six months. The amount of protection is graded according to the length of service, ranging from \$700 for six months' service up to \$3,000 for twenty years' service. The company bears the entire expense of this insurance, which is in addition to any compensation to which its employees might be entitled under the present state compensation laws. The insurance will be paid in monthly payments during the first year after death.

THE WHITMAN & BARNES MFG. CO., operator of a large forging plant in Chicago, has merged its plant with J. H. Williams & Co., manufacturer of drop forgings and tools, with plants at Brooklyn and Buffalo, N. Y.

WILSON WELDER & METALS CO., whose general offices were formerly at 2 Rector St., is now located at 253 26th St., Bush Terminal, Brooklyn, N. Y., and the Wilson Welding Repair Co. has moved its offices from 2 Rector St. to 263 First St., Jersey City, N. J.

THE FORD ROOFING PRODUCTS CO., now in St. Louis, plans to move its executive offices to Chicago and within the year to build a \$1,000,000 plant there. The new offices will be located in the Conway Bldg. J. W. Ford is president.

REER, SONDSWEIMER & CO., INC., New York City, has legally changed its name to the International Minerals & Metals Corp. The

active business management of the corporation and its relationship to its affiliated and subsidiary companies has in no way been affected and will continue as heretofore.

PROF. CHARLES H. LAWALL, dean of the Philadelphia College of Pharmacy and well-known analytical and consulting chemist, has removed his laboratory and office from 30 South Tenth Street to 636 Franklin Sq., Philadelphia.

THE CUTLER-HAMMER MFG. CO. announces the following recent installations of Thomas meters: At the Readsboro (Vt.) plant of the International Nitrogen Co., a 50,000 cu.ft. per hr. meter, measuring carbon monoxide gas given off in the process of carbide manufacture; a 300,000 cu.ft. per hr. station meter for measuring water gas in Plymouth, England, at the Plymouth and Stonehouse Gas Light & Coke Co.; another English installation is that of a 400,000 cu.ft. per hr. meter, measuring water gas; another foreign order has been received from the Brokenhill Proprietary Co., New Castle, Australia, for five 500,000 cu.ft. per hr. meters for measuring coke-oven gas. At Sparrows Point, Md., three new meters are being installed: one for the Consolidated Gas, Electric Light & Power Co., for measuring coke-oven gas pumped into the distribution system and another of 200,000 cu.ft. per hr. meter, measuring surplus coke-oven gas purchased from the Consolidated Gas & Electric Light Co., the gas at this point being under 10 to 15 lb. gage pressure; while a third at this same location is of 300,000 cu.ft. per hr. capacity for measuring surplus coke-oven gas. The Consolidated Gas Co. of New York has installed in the Westchester Light Co. plant a 500,000 cu.ft. per hr. station meter, measuring water gas. Two 1,250,000 cu.ft. per hr. meters and two 800,000 cu.ft. per hr. meters purchased by the Koppers Co. are for installation at the Chicago By-Product Coke Co., the first two to measure water gas sold to the Peoples Gas Light Co., and the smaller meters to measure surplus coke-oven gas sold to the Peoples Gas Light Co.

C. A. BREED, metallurgist, and E. M. IKUMANN, chemical engineer, have recently joined the staff of the new industrial research laboratory established in Cleveland, Ohio, by Daniel M. Luhrs.

THE CELITE PRODUCTS CO. announces that P. A. Bock, manager of distribution at the New York office, is now located at the company's Los Angeles office, where he will supervise the production work. Thomas G. Lee, Jr., will act as general sales manager, with headquarters in New York.

THE LAKEWOOD ENGINEERING CO., Cleveland, O., announces that Robert M. Gates has been appointed managing engineer in charge of the Philadelphia district of the company, with offices at 1034 Widener Bldg., Philadelphia.

THE SEMET-SOLVAY CO. has appointed J. L. Landt superintendent of the Buffalo plant, manufacturing coke and byproducts.

THE CELITE PRODUCTS CO. announces that it is now represented in the Buffalo district by the Empire Co., 331 Ellicott Square, Buffalo, N. Y.

GUSTAVE DROBEGG, consulting chemist, specializing in intermediates for dyes, pharmaceuticals, essential oils and synthetic aromatics, announces his removal from 38 Park Row to 5 Beekman St., New York City.

THE BETHLEHEM FOUNDRY & MACHINE CORP. has purchased the business of Stevens Bros., 149 Broadway, New York. All of the personnel and staff of Stevens Bros. are retained and the Bethlehem Foundry & Machine Corp. will conduct a business as engineer and contractor to the chemical industry at 149 Broadway, New York City.

THE CRESCENT PRODUCTS CO. of Hartford, Conn., was recently incorporated to deal in chemical formulas, etc. The organizers of the company are J. L. Porcheron, H. G. Wilson and W. E. Chapin, attorney of 874 Main St., Hartford, Conn. The capital of the new company is \$10,000.

THE MONO CORPORATION OF AMERICA announces the removal of its main office from Buffalo to 25 West Broadway, New York City, where its complete line of automatic continuously recording gas analyzing instruments for CO₂, CO, O₂, SO₂, H₂, N₂, CH₄, etc., will be displayed. F. D. Harger, vice-president and general manager, D. W. Reid and others will offer chemical service in matters relating to the automatic, continuous recording of gas analyses in the scientific control of combustion and chemical processes.

Facts First;

Classification Second

THE coal operators shipping over the Virginian Railway for export through the Sewalls Point Coal Exchange are taking a very advanced stand in their agreement with the United States Bureau of Mines with regard to the sampling and analysis of coals. They propose to have a complete set of mine samples and analyses, tippie samples and analyses, and commercial coal tests throughout the year to serve as a basis for determining the classification of their coal shipments.

As in all such co-operative agreements, all analyses obtained by the bureau may be published, and all users of smokeless and high volatile fuel from this district can therefore profit by the conclusions. This work will be of great value to other users of coal from this territory as well as to the tidewater and foreign interests directly concerned in the shipments handled by this coal exchange.

This is practically the first time that a large group of operators have been willing to face the facts so frankly; they and their patrons are to be congratulated accordingly. It is not too much to expect that other districts will fall in line, so that all users of fuel may ultimately have reliable mine- and commercial-coal analyses as a basis upon which to judge their purchases. The time is coming when a coal purchaser may again buy upon quality. Just now, of course, he has to take what he can get and be thankful for that. When quality again becomes the determining factor such work as this just undertaken will have increased value for all.

New Problems

In the Chemical Industry

HIGH prices and increased transportation costs necessitate industrial adjustment. In what way will this adjustment affect the chemical industry?

Like others, the chemical industries have shown a marked tendency toward centralization and large-scale operation. This has not been illogical and has done much to bring about the high efficiency and the present position of importance of the chemical industry in this country. There were other and less apparent causes for centralization, among which the low cost and ease of transportation and a relatively concentrated market were important. Also there was a lack of appreciation on the part of the investing public of the economic importance and industrial stability of the chemical industry. Men whose initiative, ability and training fitted them to establish and operate small chemical plants felt that the large chemical companies offered more attractive employment and a greater opportunity.

Now, however, the conditions have changed in a marked degree. Industrial expansion throughout the country and more particularly the increase in general manufacturing in Western states, which has called for larger quantities and varieties of chemicals, have emphasized the burdensome effect of centralization in those sections distant from the source of the needed chemicals. Transportation difficulties and more recently the increase in freight rates have forcibly emphasized this effect of centralization. As a consequence interest has been stimulated in small-scale production to supply a local market.

Undoubtedly the small plant will become an increasingly important factor in the chemical industry, and bring about a new set of problems for chemists and chemical engineers to solve.

Why Not a Revolving Fund?

CHEMICAL Warfare Service is to embark upon many activities which have possible peace-time value. These activities should be fostered, for the Service can be most effective in war times if it has been allowed to be business-like and effective in times of peace. One specific proposal is that a portion of the war-gas reserves be sold each year and a new supply be made in the plants of C.W.S. to replace the amounts disposed of. This would permit only fresh stocks to be kept and continual attention could be given to revision of manufacturing methods and maintenance of plant and equipment in genuine working order.

Any such program still has one important limitation, however. The income from such sale of materials would not be credited to the accounts of the Service for further developments and operations. It is a general practice that such income incident to any Government activity "be covered into the Treasury as miscellaneous receipts." In other words, the Service, although in effect financially self-sustaining, has each year no income credited to it, for these miscellaneous receipts do not appear as part of its assets. Occasionally a somewhat different practice is followed under what is termed "a revolving fund." An appropriation for this purpose provides that any income from the work authorized shall be credited to the appropriation and thus be allowed to facilitate an extension of the work or its continuance beyond the time that the initial appropriation would provide for.

Far be it from us to encourage Chemical Warfare Service or any other branch of the Government in the thought of "going into business" in competition with established industry. However, to remain an effective military agency this department must be maintained upon a business-like basis. A most effective means to

this end would be the transaction every year of a small amount of business directly associated with industry. The personnel of the Service would thus be kept in touch with industrial conditions most effectively and would know just how the current work could most quickly be expanded to a larger scale in case of military emergency.

A relatively small appropriation will permit fairly large-scale operation of the Service if the appropriation is on the basis of a revolving fund. On the other hand, if definite appropriations for all work must be made every year and income simply goes into the Treasury of the United States, we know there must be a continual fight in Congress to obtain the necessary money. Each year the effectiveness of the Service will be jeopardized by the possibility of political attack or unreasonable so-called "economy." It seems that an appropriation on the basis of a revolving fund would have great merit in these circumstances.

Fees vs. Salaries For University Professors

NOTING the inadequate technical instruction in iron and steel now existing in America, not only in trade schools but more especially in the so-called institutions of higher learning, the president of one of our honorably known colleges set out to find a professor of ferrous metallurgy. He wanted to find a man of personality such that men in the surrounding industry would naturally come to him for advice; the new professor was to be an executive who could lay the foundations for a great department; he must know iron and steel metallurgy and metallography, and be able to speak and write on these subjects clearly, easily and convincingly.

Some well-meaning friend referred Dr. PREX to us for a list of possible candidates. After hearing the specifications and learning that the salary of \$4,500 a year was offered, the answer was instant: "It simply can't be done! Metallurgists of that caliber are extremely rare. If you could find one it would be difficult to interest him at twice the figure. If you succeed it will be pure good fortune."

"True," said the visitor, "but I hope to interest some man already a teacher, or with a desire to become a teacher, who is perhaps even now occupying a subordinate educational position, and who might not be held by a consulting practice, and therefore be willing to make the change for the opportunity it offers."

Here, indeed, is a phase of the situation only now being realized by educational administrators. Granted that an engineering professor should do some consulting work in order to keep him familiar with the shifting advance of technology, it is often forgotten that the teacher's first duty and great opportunity is to instruct and inspire his students. If his salary for this welcome task is so pitifully inadequate that financial worries and half-baked consultation fill his mind and time, then the teacher is teacher in name only, he loses his upright independence and the honorable title "Professor" is truckled to quack and charlatan.

Inbreeding and stagnation in university faculties are an ever-present danger from many causes without tying a teacher to a certain city or region simply because he is reasonably sure of certain outside fees. Why should he go from hardly won pound cake at Harvare to several years of bread and butter at Illiota?

Dr. PREX has evidently seen the great need of competent instruction in iron and steel. When will his board of directors apply to college management the same principles which rule their business; that the man and not the salary is the thing of importance? They know that if they get the right man he will earn the salary he will ask, but it seems they have not yet received sufficient urge from teachers, alumni or industry to act upon that knowledge.

An Excellent Publication On Hydro-electric Power

A PAMPHLET has been circulated by the Guaranty Trust Company which looks like good tidings. It urges investment in hydro-electric enterprises. It consists in a study of the power facilities of the United States, recognizes the prospective exhaustion of our oil supply with the increasing demand made upon it and the imports, running up in 1919 to 70,000,000 barrels. The burden upon railways for carrying coal is considered, as is the increase of 175 per cent in the cost of coal at the mines since 1914. The immense saving of labor and in traffic to be obtained by the development of water-power stations instead of hauling coal and the reasonableness of co-ordinating these with central-power stations fed by steam and gas are set forth with such clarity that it seems—of course this is a venturesome statement but it *almost* seems—as if it might make the dear public understand something of the thefts that we of today are committing against unborn generations.

There is told also how in the electrified mountain section of the Chicago, Milwaukee & St. Paul Railway (which formerly bore the initials C., M. & P. S. and was sometimes referred to as the Chicago, Milwaukee and Paint Saul), the company found that one electric locomotive does the work of four steam locomotives. The Butte, Anaconda & Pacific Railway accomplishes with seventeen electric locomotives work that formerly required twenty-eight steam engines of the mastodon type. The Norfolk & Western Railway achieves similar results. The interconnection of seventy-five hydro-electric with forty-seven steam plants in California covers a distance of over 800 miles with 7,200 miles of high-tension transmission lines, having a capacity of 785,000 kilowatts and serving nearly 600,000 consumers. California uses more electric power on farms (chiefly for pumping water for irrigation) than all the rest of the farms in the United States. The California rice industry that began in 1912 and that last year produced a crop worth \$27,000,000 is almost wholly dependent on electric pumping.

In Kansas this summer the wheat of at least a dozen counties was threshed by electricity. One company supplies power to sixty towns and 500 farms. In Montana and Idaho the mines and smelters are electrified, and in the Northwest paper mills and sawmills are using electricity for power. And the immense significance of long-distance transmission whereby manufacturing concerns may select the most convenient locations, instead of building out at the falls, is emphasized.

We congratulate the Guaranty Trust Company on rendering a real service in public education. The public is naturally conservative in regard to what it does not understand, and this is as it should be. But it is also very slow in trying to understand, and this is as

it should not be. There are indications, however, that the passage of the water-power bill at the last session of Congress is stimulating hydro-electric development in this country. Up to September 19 the Federal Power Commission had received fifty-six applications for preliminary permits and licenses. These applications are being filed from all parts of the country and the power is to be used for a variety of purposes, including mining, irrigation and public utility service.

Don't Forget

The Time Element

A GREAT many persons by losing sight of the time element, are in danger of misinterpreting or of failing entirely to perceive the economic changes that are in progress. They forget that time has passed and time is passing. That is a common fault. It is the chief thing, for instance, that makes an "old foggy" what he is. The passage of time makes less impression upon the older man and he expects events to move less rapidly in keeping with his duller impression. The man who does not become an old foggy is the one who makes allowance for the change in personal equation.

We are in a period of particularly great changes and especially rapid flux by reason of the great war having occurred. The passage of time is especially important as suggestive of the passage from one set of conditions to another set and still another. What many men neglect to allow for is the fact that almost two years have passed since the Armistice.

The idea entertained during the war in some quarters that there would be a period of readjustment or a "transitory period" from war-time conditions to stable peace conditions in the matter of business and the affairs of men generally has been shown to have been altogether erroneous. We are to have continued changes. At the present time there is in progress a downward readjustment in the values of many things. In the case of commodities, the great bulk of commodities is included. In the case of labor, the rates in money per hour or per day do not decline, but the performance increases, and while the labor unions consider labor a commodity to be weighed out simply by time, the fact is that in the long run the workman sells performance, which one may regard as service rather than as a commodity.

There are not a few who shrink from the mere contemplation of such a thing as declines in the prices of commodities. They seem to think it will spoil everything for prices to decline. They forget that almost two years have elapsed since the Armistice. They fail to allow for the progress of time. We have had a period of price advances—and quite a long period considering how rapidly things would naturally move after such great disturbances as the World War could not but produce. It is only natural that at some time prices should decline. During the war the common prediction was that there would be a "period of prosperity" after the war, and some predicted only three years of that. Well, two years have elapsed and they have not been years of real prosperity, which means both progress or advancement and contentment. These things obviously we have not had, and if they were possible in the circumstances that existed they would have obtained. Others, the most sanguine, predicted a period of seven or eight years of "prosperity." Assuming for argument that they were right, a fourth of the

period has passed and has been practically squandered. If the fates really do decree that when mankind indulges in a great war with enormous destruction of life and property and great waste of time it shall be rewarded by being given a period of riotous living, how many years of such reward is mankind entitled to receive?

The thing to do is to recognize that the two years have not given us real prosperity and that they represent an amply long period for the experiment. We should be glad to see things change, for any change would be promising of better luck in the next experiment. If we do not have changes, if we do not try various means of arriving at real prosperity, we might as well take it that the world has gone to the dogs to stay there.

First in War, First in Peace, and

First (?) in the Hearts of the Congressmen

THE Chemical Warfare Service is undertaking a most desirable public responsibility when it seeks to apply during peace time some of the important results of its military preparedness. The chemist can do well to follow the various activities of this Service, for doubtless much of its effort will prove to have immediate commercial application as well as the military value primarily sought. In this connection it is interesting to note the efforts toward rat extermination with poison gas, the possibility of poison-gas bombs being used in the capture of criminals who have barricaded themselves in inaccessible places and the destruction of grasshoppers and other pests by appropriate offensive gas preparations. These, of course, have a popular as well as a technical interest.

To the chemical industry it will be more interesting to consider the proposal that the stocks of war-gas materials be used industrially to a certain extent each year. By this plan it is hoped that the facilities and equipment of the Service may each year be actively in use on a small scale and thus be more easily maintained up to date and in operating condition. The sale of 25 per cent of the reserves of chlorpicrin and phosgene each year is one of the specific suggestions to this end which would permit co-operation of the Chemical Warfare Service with the dye interests. Numerous other means of co-operation will suggest themselves also.

It is certain that these efforts will afford a most encouraging element upon which to base our support of the needed increases in financial backing for the C.W.S. Congress will doubtless be asked to appropriate considerable sums next winter to augment the facilities for additional research work needed. If the chemists diligently study the opportunities for peace-time service of this branch of our military organization they can most enthusiastically and effectively support these requests. Our profession is signally recognized by the maintenance of this branch of the Army and it is a responsibility of the profession to support the Service accordingly. The proposed advisory committee of chemists which the American Chemical Society is to appoint to work with the C.W.S. will be one medium through which our support may be afforded, but an individual responsibility of chemists is equally important, especially wherever there is opportunity for industrial application of or co-operation in C.W.S. activities.

Readers' Views and Comments

College and University Finances

To the Editor of Chemical & Metallurgical Engineering

SIR:—All our educational institutions have recently felt the pinch of limited resources, and many have made strenuous efforts to raise large endowments, intended for the most part to increase the salaries of the teaching staff.

This whole idea is essentially undemocratic and un-American, so long as the colleges and universities do not make a charge for tuition equal to its actual cost. As long as this condition exists, increased endowments to make up the deficit are in the nature of charity and tend to pauperize the beneficiaries—i. e., the students or their parents paying their tuition.

At the present time no one of these institutions has stamina sufficient to charge for tuition its actual cost. Rich and poor alike are charged the same, an average of about one-half the actual cost. Neither the rich nor the poor are informed as to the actual cost being double the price charged, and the rich are not even invited to pay the cost.

No one with the true American spirit wishes to educate his children at less than its cost, if he is able to pay the cost. But our universities proceed on the tacit assumption that the preceding statement is untrue, that the American parent always wishes to get the education at as low a figure as possible and to avail himself as far as possible of the endowment funds which charitably disposed persons have contributed to assist the colleges in their work. I am firmly convinced that this tacit assumption is the one that is totally false; that the American spirit recoils from accepting charity and prefers to pay the proper price and preserve its self-respect.

One result of the charge for tuition being placed at only a fraction of its actual cost is that the more students in attendance the greater is the strain on the institution's finances, the more endowment is needed to meet the deficit, and, in general, the more the institution has to plead poverty and to cut to the lowest possible figure all expenditures, such as salaries of the teaching staff, etc. Our institutions being of late notoriously overcrowded, it results that the greatest sufferers are the teaching force, the restricting of whose salaries is the chief avenue open for economy. We can say with almost absolute truth that rich men's children are being educated in our colleges at half price largely at the expense of the teaching staff, whose salaries must be restricted to the minimum if the institution is to make ends meet.

Is the proper remedy for this condition to appeal to wealthy patrons generously to donate large endowments whose income shall go to increasing salaries of the teachers? Is this not adding insult to injury? It surely should appeal to level-headed business men rather to solve the question by making the charge for tuition its cost, which would then be paid by all able to pay it. In this way, the parents do not receive charity from the institution's endowment in the form of tuition for their children at half its cost; neither

are the teaching staff receiving living wages from endowment provided by generous and wealthy patrons.

What is needed is a return to normal, healthy business methods in the running of our higher educational institutions, and to give the independent American the chance to pay for what he is getting. Departure from such a principle causes most lamentable confusion, plainly evident to those who will study the subject dispassionately and sanely.

The writer is a university professor, receiving as salary only a fraction of what his services would command industrially; the same is true of my assistants. The university could pay me and my assistants increased and more proper salaries if full cost of tuition were paid for those students whose parents are able to pay it. Out of whose pockets, then, is this deficit coming? It is a fallacy to consider it as coming from endowment; it really is extracted, under present circumstances, from the salaries of the teaching staff. The well-to-do parents should be given the opportunity to right this wrong, and the proper remedy is to make the charge for tuition equal to its cost.

The only valid argument against this innovation is that it will prevent large numbers of worthy students from getting an education because of inability to pay the cost. It may be admitted at once that under the proposed new charges, more students will be unable to pay the charge than at present. But that is not an insuperable difficulty. At present, no worthy student who shows good scholarship is turned away for inability to pay tuition. He either gets a scholarship, intended to help just such men, or else he is granted "deferred tuition" for a half, a quarter, or all the tuition charge. This means that he pays what he can, and the college lends him the rest, he promising to repay it, without interest, as soon after graduation as he is able. This is the right and proper use of endowment funds; to help those who need help, and not foolishly to waste it on those who need no help and can pay the full cost of tuition.

Adoption of the proposal to make the tuition charge the full cost of tuition would liberate endowment funds now misapplied and turn them into the proper channel of assistance to worthy students not able to pay the cost. No worthy student need then be turned away, there are all grades of financial ability and disability among students; no one would be asked to pay more than the mere cost, no matter how rich he or his parents. For the fraction unable to meet this very reasonable requirement, the endowment funds should be wisely appropriated, so as to make up the difference between cost and the students' ability to pay. Most of this would come back to the institution a few years after the recipient graduated, and thus the endowment funds would not be diverted but largely returned.

Concrete application of this abstract principle will show that it is practicable and financially sound, as well as being ethically far superior to the present antiquated and absurd system. Adoption of the system advocated will put endowment to work in its proper channels,

will increase the self-respect of the students, who will feel that they are not objects of charity when the cost of their tuition is being paid, will increase the self-respect of the American parent who pays the full cost of his children's education, will enlighten the financial burdens of the institution by making income more nearly proportional to expenses, and will enable the institution to apply the sums saved to the increase of salaries of the teaching force, where they properly belong, and whence they are at present being unwisely and unnecessarily diverted.

Are endowments made to higher educational institutions intended to help educate well-to-do people's sons at half cost, or to help educate those unable to pay the simple cost of their education? Should the compensation of the teaching staff be restricted to less than proper living salaries to make it possible to educate well-to-do people's children at half the cost?

Lehigh University,
South Bethlehem, Pa.

JOSEPH W. RICHARDS.

Massachusetts Institute of Technology School of Chemical Engineering Practice

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—The School of Chemical Engineering Practice of the Massachusetts Institute of Technology, which was started in 1916-17 and then discontinued on account of the war, has been reopened. The work of this school is part of a 5-yr. course in chemical engineering offered by the Institute and consists of twenty-four weeks' field work at three chemical engineering practice stations. These stations are located at Bangor, Me., Everett, Mass., and Buffalo, N. Y. The plants co-operating with the Institute in this important educational work are the Eastern Manufacturing Co., manufacturing electrolytic bleach, sulphite pulp and writing papers; the Penobscot Chemical Fibre Co., Oldtown, Me., manufacturing soda pulp; the Revere Sugar Refinery, Charlestown, Mass.; the Merrimac Chemical Co., Everett, Mass., producing heavy chemicals; the Boston Rubber Shoe Co., Malden, Mass., the Lackawanna Steel Co., Buffalo, N. Y., and the Larkin Co., Buffalo, N. Y., manufacturer of soap, etc.

In the practice school the students study the various unit chemical operations such as filtration, evaporation, combustion, etc., on full-scale apparatus and under practical working conditions. Sometimes this is accomplished by actually working with the operating men, and at other times by running a full-scale test to determine either the efficiency of the equipment or process, or to find optimum conditions of operation. Such tests are always carried out under regular factory conditions without interfering with the quality or quantity of the output and are along lines which are of interest to the co-operating companies. Work at the Bangor station includes investigations into the production of chlorine and bleach, the absorption of SO_2 in the manufacture of bisulphite liquor, the efficiency of quadruple effects evaporating caustic soda solutions, etc. Work of similar character but along different lines is carried out at the other stations.

The students will complete their work in the practice school at the end of December, and will then return to the Institute for two terms of advanced study. This advanced work is wholly elective and enables the student to specialize in that line of chemistry or engineering in which he is most interested. In the choice of courses and in the viewpoint toward this advanced work, the

student will be greatly benefited by the practical plant experience he receives in the field work of the practice school.

There is one important difference between the School of Chemical Engineering Practice and other co-operative engineering courses, where the student is regularly employed for part of his time in the factory, and the remainder is spent in class room and laboratory work at the college or university. This difference lies in the fact that instead of being on routine factory production work, as is customary in such courses, the student in the School of Chemical Engineering Practice is always under the direct charge of a resident faculty member at each station and the student's work is so planned that he shall obtain the greatest possible benefit from the time spent in the plant.

Two matters which have occupied considerable attention in scientific and engineering circles are the education of future engineers and the establishment of closer relationship between the work of the university and that of industry. In the School of Chemical Engineering Practice, progress along both of these lines has been made, and a great forward step taken in the sound, rational education of the Chemical Engineer.

Cambridge, Mass.

R. T. HASLAM,
Director.

Self-Contained Engineering Journals

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—With so many highly-specialized engineering journals in the field, a reader who wishes to keep in general touch with engineering has to do as Thomas Edison does and read them all. A recent magazine article (was it in *Engineering and Contracting*?) reported that Edison reads regularly fifty-two technical periodicals. Even then the average reader is bound to miss much that he would like to see, and he really cannot expect anything else. The best that he can do is to find the majority of the best articles that discuss his particular hobbies.

For instance, a reader interested in the cyanide process for gold ores can find suggestive articles in *Engineering and Mining Journal*, *Mining and Scientific Press*, *CHEMICAL & METALLURGICAL ENGINEERING*, and several of the publications of the chemical societies. Of course, a member of the staff of any one of these periodicals will assert that his particular paper publishes all that is worth seeing, but that is not true. Each paper has its merits.

The point I am getting at is, Why do not the editors of the various engineering journals acknowledge more often that such and such a paper has printed an unusually good article on this or that? The readers undoubtedly would be glad to hear about it, and would credit the editor for his fairness and generosity. Most engineers subscribe to only one technical journal, and would be glad to know from an editorial note that an unusually good article on some particular subject has appeared in another paper, which they could refer to at a library.

In other words, are not engineering journals too self-contained? Are not the editors too chary of praising or acknowledging or even criticizing (good criticism helps enormously) the achievements of other journals? American engineering journals are, if anything, too highly specialized, but why can they not make up for it by passing the news around of something worth while in the other papers?

Synthetic Production of Hydrocarbon Fuels

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—I have read with great interest Edward G. Acheson's letter in your issue of Aug. 18, p. 268, and while disclaiming much knowledge of chemistry outside of my business, yet, in view of what has been accomplished, the synthetic production of hydrocarbon fuels does not seem impossible.

This leads to the thought that should synthetic hydrocarbon be produced it is more than likely that the fuel will be a simple compound, and not a conglomerate of a dozen hydrocarbons such as we now obtain from the crude, each with its own boiling point and other individual peculiarities that in combination produce most of our troubles with the internal combustion motor.

For example, should it be possible to produce pure pentane, the designing of carburetors would at once be a simple matter, and nine-tenths of our motor troubles would vanish.

I am also led to think that Mr. Acheson is perhaps the one man in this age who by training, accomplishments, physical resources and financial independence is best equipped to tackle the problem.

Nitrogen Fixation in the Soil by Inoculation

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—I am firmly convinced that soils may be profitably inoculated by azotobacter and possibly other large-celled organisms, in order to provide for the non-symbiotic fixation of nitrogen under adequate control, and believe that in time a method will be developed which will economically take the place of commercial nitrogenous fertilizers. However, we have not continued our investigations along this line since the publication of Bulletin 45, but are in hopes of doing so in the near future.

This station does not recommend the purchase of commercial nitrogen for Iowa conditions, believing that by a judicious use of inoculated legume and the proper handling of farm manures the supply may be made adequate. I believe, however, that by a further inoculation with azotobacter at some period during the rotation the excess carbohydrates in the soil may be utilized by these organisms to produce even greater quantities of nitrogen than is produced at present by the symbiotic organisms.

Resistance Between Cup and Lip

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—Your editorial on "Resistance Between Cup and Lip" hits the spot. Several years ago while in Szechuen, China, I saw the wonderful possibilities of a complete industrial development of a backward country and prepared a preliminary survey and suggested plan. American manufacturers would not even consider co-operating with us in the plan; others wanted knowledge of the markets to be sent to them but were not willing to supply any funds to get the needed information.

A company organized to get the information and digest it, proposing same to the right parties, has a big, useful and most interesting field of opportunity.

Middlebury, Conn

Phosphate Rock Deposits in Morocco

BY JAMES C. MARTIN

THE large and growing demand for phosphate rock and superphosphate fertilizer in Europe justifies the keen interest with which American producers have received rumors of the discovery of additional large deposits of phosphate rock in western Morocco. A shortage of shipping in the Mediterranean has recently prevented the producers of rock phosphate in Tunis and Algeria from shipping from abroad all they could deliver to the docks, but the quantity thus delivered is at best insufficient to supply the present European need. Accordingly, though the discovery of vast deposits of rock phosphate may not afford a means of supplying the demand at once, the adequate working of the deposits and the marketing of their output will furnish additional competition with the American product.

For the information of Americans who are interested in the phosphate industry the following data regarding the deposits in Morocco have been compiled by the Foreign Mineral Section of the United States Geological Survey, Department of the Interior.

France has a mild form of monopoly over the output in Tunis and Algeria and allocates a part of each year's output to other European countries in rough proportion to their estimated needs, taking in exchange other materials required for the manufacture of superphosphate, such as coal, pyrite and sulphur. In addition to her deposits of phosphate in Algeria and Tunis, France controls vast undeveloped deposits in Morocco. These deposits are said to be extremely rich, containing hundreds of millions of tons, worth billions of dollars to France and capable of furnishing considerable aid in rehabilitating her war-depleted treasury. If current reports concerning the high grade and great extent of these deposits are true, France will be in a dominant position in supplying Europe with phosphatic fertilizer. Her allocation of African phosphate in 1919 and 1920 to the countries in Europe and the requirements of those countries are shown in the following table, but on account of the lack of vessels the quantities actually delivered to many countries in 1919 were only fractions of the quantities allocated.

PHOSPHATE REQUIRED IN EUROPE IN 1919 AND 1920 AND FRENCH ALLOCATION OF AFRICAN ROCK FOR THOSE YEARS*

Country	Required		Allocated		Per Cent of requirement
	Tons	Per Cent	Tons	Per Cent	
France	1,100,000	42	700,000	50	64
Italy	600,000	23	355,000	25	59
England	400,000	15	247,600	18	62
Spain	200,000	8	73,600	5	37
Belgium	100,000	4	3,600		4
Netherlands	100,000	4			
Portugal	50,000	2	14,700	1	29
Scandinavia	40,000	2			
Switzerland	10,000		5,500		
	2,600,000		1,400,000		54

* Adapted in part from *American Fertilizer*, vol. 52 (1920) p. 140.

† Nearest whole number

The intensification of agriculture in the countries recently at war will create a large demand for phosphate, and the exploitation of the Moroccan deposits will undoubtedly disturb the American phosphate industry. At present, however, European consumers cannot obtain more than a fraction of the phosphate they need from America.

The Flow of Oil in Pipes—I

A General Method for Determining the Friction Loss of Any Liquid From Its Saybolt Viscosity; With Tables for Pipes From One to Six Inches in Diameter

BY ARTHUR C. PRESTON

THE following discussion of the flow of viscous liquids in pipes aims to develop a method for determining friction loss as a function of the viscosity and density of the liquid. The viscosity may be taken either in absolute units or as the time of flow through any commercial instrument which can be accurately calibrated with respect to the absolute unit. The appended tables are based on viscosity-seconds as measured by the Saybolt Universal Viscosimeter, because that is the standard of viscosity measurement most frequently employed in commercial practice, and it is thought that in this form the tables will be found most generally useful.

The present discussion relates primarily to the flow of mineral oils, but the method is general and may be applied to any other fluid.

The most accurate and important part of the experimental data on which these conclusions rest is the work of other investigators, although it is corroborated in all essential points by the results of a fairly extensive series of experiments on the flow of oil in wrought iron pipes which the writer carried out several years ago at the University of Colorado. The writer's part in the present instance has been chiefly to correlate and adapt the work of others, so as to put the whole in familiar and convenient form for use in general engineering design.

FACTORS AFFECTING RATE OF FLOW OF LIQUIDS THROUGH PIPES

The rate of flow of a liquid moving through a pipe under a gravity head is influenced primarily by three characteristics of the liquid itself—namely, the density, which supplies the pressure producing flow; the viscosity, which retards flow; and inertia, which under certain conditions manifests itself in the dissipation of energy by the collision of eddying particles. These three constitute what may be called the internal group of factors affecting flow; the other factors, such as the diameter, length and roughness of the pipe, and the amount of the gravity head, may be called the external group; and the latter, although of great importance in their bearing on the final resultant flow, are secondary in the order of consideration of the problem as a whole. Any or all of the external factors may in practice be varied at will, and the resultant flow will respond to these variations according to laws which may be experimentally determined and analytically stated; but underlying all the observed phenomena are the fundamental limitations to flow imposed by those inherent properties of the liquid which have been described as the internal group.

It is essential to grasp this distinction clearly at the outset of any attempt to consider the general problem

of liquid flow, because it is entirely lost sight of in the account of hydraulic theory which is commonly made available for engineering study and reference. In the presentation of that theory the factors of the internal group are usually entirely neglected. They are left out of consideration because they are nearly constant for water at ordinary temperatures, and the laws deduced from hydraulic experiment are only those which exhibit the influence of the external group. Hydraulic flow is a very special case of liquid flow; hydraulic theory is not at all an exposition of general liquid theory, but applies only to such liquids as have the same density and viscosity (or more accurately the same ratio of density to viscosity) as water; and indeed the laws as usually stated apply only to a limited range of velocity even for such a liquid.

Hydraulic tables do not furnish a satisfactory basis for estimating the flow of any other liquid, even when the internal characteristics of the latter are known; but when the general solution for the problem of liquid flow is obtained it takes the place of hydraulic formulæ and gives the same results, simply by substituting in the general formula the physical dimensions of the pipe and the values for the particular density and viscosity of water.

DATA FROM RESEARCH INVESTIGATIONS APPLIED IN PRACTICAL FORM

Experimental work leading to this general solution has been carried on in recent years by numerous investigators, influenced greatly, no doubt, by the rapid development in the use of mineral oils in the industries and the consequent need of rational methods for designing oil piping. Out of a number of valuable researches which have been published, each contributing to some phase of the question, two in particular have seemed to cover the ground most satisfactorily; these are two series of researches on the flow of air, water and oil in pipes, conducted and published by the British National Physical Laboratory,¹ which have not had wide currency in this country. Just after the publication of these came a third work, the standardization of the Saybolt Universal Viscosimeter, by the Bureau of Standards,² which taken in conjunction with the theory developed in the two first mentioned has made it possible to adapt that theory to practical form for the use of engineering designers. From these sources, whose conclusions are confirmed by the work of many other experimenters, it has been possible to compile the tables which are presented herewith, showing the discharge for a given pipe and head, for liquids of any density and viscosity, simply by reference to the time

¹Collected Researches, National Physical Laboratory, Teddington, England, Stanton and Pannell, vol. 11, 1914, and Pannell and Higgins, vol. 13, 1916.

²Winslow H. Herschel, Bureau of Standards, Technologic Paper No. 112, Washington, 1919.

of flow through a standard commercial viscosimeter. It is believed that the first published tables of this form were those offered by the writer in his report of the work done at the University of Colorado, which are now superseded by the more accurate tables given in this article.

The method of developing the process was briefly as follows:

It had been demonstrated¹ that in a given pipe at constant velocity, the head lost in friction is the same for all liquids which have the same ratio of density to absolute viscosity. This was substantiated by experiments on large and small pipes, at high and low velocities, with fluids of such varying viscosity as air, water and oil. The general relation between these factors had been derived, so that only a knowledge of the values of density and viscosity was required to make it available for the solution of any given problem.

Second, the standardized Saybolt Universal Viscosimeter had been calibrated² so that it could be used as a means of determining these values, and this work had shown that liquids having the same ratio of density to absolute viscosity have the same time of flow through the Saybolt instrument.

As a result of the foregoing, the conclusion is drawn that liquids of equal Saybolt viscosity have equal pipe friction losses, and means are given for computing friction loss from Saybolt viscosity as primary data. To this are appended tables, which have been computed for convenience of reference.

KINEMATIC AND ABSOLUTE VISCOSITY

Viscosity may be defined loosely as the internal friction of a moving liquid. In set terms, it is the force required to move a plane surface of unit area past another at unit distance, at unit rate of speed, the space between being filled with the viscous liquid. Various means may be devised for measuring this force; as, for instance, by dragging a solid body with flat surfaces through the liquid and noting the pull exerted; but the form of instrument most frequently used consists of a tube of narrow bore and relatively great length, through which the liquid moves under a small gravity head at low velocity, so as to prevent eddying. The moving body may be considered as made up of an infinite number of concentric cylindrical films of infinitesimal thickness, all moving forward along the axis of the tube. The outermost film wets the wall of the tube and sticks fast there; the next film slips or shears over the first at a rate which depends on the viscous resistance of the fluid; and so on to the center filament, where the motion is fastest. The resistance to slipping of one film surface over another, which corresponds in some degree to the phenomenon of friction between the surfaces of solid bodies, is the measure of the viscosity of the liquid. It is evaluated by integrating the sum of all the resistances from the circumference to the center of the tube, and equating this sum to the pressure due to the gravity head, less the velocity head, since all the pressure, except the small amount which appears as kinetic energy, was used up in overcoming the slippage resistance and consequently is equivalent thereto. The method will be found fully explained by Archbutt and Deeley,³ and is the basis of the design of the Saybolt and similar flow-

type instruments. The mathematical expression for the absolute viscosity is

$$\mu = \frac{\rho g r^2 h}{8 v l} \quad (1)$$

Where ρ = density in grams per c.c., or pounds per cu.ft.

g = gravity = 981 cm., or 32.2 ft. per sec. per sec.

r = radius of tube in centimeters or feet

h = head in centimeters or feet

v = average velocity of flow in centimeters or feet per second

l = length of tube in centimeters or feet.

This gives μ , the coefficient of absolute viscosity, in dynes per sq.cm. or in poundals per sq.ft., according to the system of measures employed. The equation applies only to the condition of steady or non-eddy flow.

The conversion factor between the two ways of expressing absolute viscosity is 14.9, by which the c.g.s. value must be divided to give the English equivalent. For most purposes it is more convenient to deal with

the ratio, $\frac{\mu}{\rho}$, which is called the kinematic viscosity

and is the quantity measured by commercial flow-type viscosimeters. The conversion factor for kinematic viscosity is 929.03, by which the c.g.s. value must be divided. The c.g.s. system certainly is more convenient for laboratory use, and is adopted in most of the investigation and literature of viscosity; but in the present case it is necessary to use the English units in order that the theory as developed may be applied directly to our everyday practice of making measurements in that system.

EDDYING FLOW

From the form of equation (1) it may be seen that for the condition of non-eddy flow, the relations of the governing factors are very simple; and this kind of flow characterizes many cases of practical interest, particularly with small pipes or with liquids of high viscosity. Since the rate of variation of all these quantities is linear, it follows that, if the friction loss for a given combination of factors be known, the loss due to any variation in these factors may be deduced by simple proportion, throughout the range in which the equation holds good; or, the loss for any case may be determined by substituting the proper values for viscosity and density in the equation. Further, it is seen that when the pipe dimensions and velocity are constant, friction losses are equal for all liquids having the same kinematic viscosity. Now it will be shown later on that liquids of equal kinematic viscosity have the same time of flow through a Saybolt or other viscosimeter of similar type; from which it follows that liquids of equal Saybolt viscosity have equal friction losses, at least throughout the range of velocity in which flow is steady, and, as will be demonstrated, for all higher velocities also.

This relation then might have been of considerable use to pipe line designers in the past, but for two principal facts; first, that designers rarely have means for determining absolute viscosity, and even if they know the Saybolt or other commercial viscosity of the liquid with which they deal, they do not know how to convert it to units of absolute viscosity; second, that equation

³Archbutt and Deeley, "Lubrication and Lubricants," Griffin & Co., London.

(1) applies only to a limited range of low velocities, and breaks down entirely at the point where eddying begins, leaving the friction loss at all higher velocities to be determined by methods which until recently were not thoroughly studied or understood.

If a liquid be set flowing in a pipe at a low but steadily increasing velocity, the phenomena at first are those of the steady flow which has just been described, the increase of friction head being linear or as the first power of the velocity. When a certain rate of flow is reached a sudden change occurs, and equation (1) no longer holds. This new régime begins with a brief period of uncertain flow, during which friction loss increases at a much greater but variable rate, until when another definite velocity is reached a second sudden change occurs, and friction loss thereafter increases regularly, but more slowly than in the preceding stage. If the smoothness of the pipe is equivalent to that of drawn piping, the rate of increase is approximately as the 1.74 power of the velocity. This is the régime of eddy flow.

CRITICAL AND POST-CRITICAL VELOCITY

The point at which the first change occurs is quite definitely fixed by the relations of viscosity, density and diameter of pipe. It is determined by the so-called Reynolds criterion,

$$r \rho d = R \quad (2)$$

where R is a number which undoubtedly varies somewhat with the roughness of the pipe, but which for smooth drawn pipe or tubing is quite accurately equal to 2,050. The point at which the second change appears is fixed in the same way by another value of the same expression, which for want of a better name may be called the post-criterion, where R for the same kind of pipe equals 2,900. The velocity at the first point is called the critical velocity, and that at the second point may be called the post-critical velocity.

The explanation of these changes, as was developed by the work of Osborne Reynolds,⁴ is that at the critical velocity the steady or stream-line flow of concentric cylinders sliding over each other is broken up, and the particles of liquid begin to eddy and whirl, using up in the friction and impact of collision the extra head which makes its appearance at that point.

MATHEMATICAL ANALYSIS OF B. N. P. LAB. DATA

A graphic illustration of the relation of velocity to friction head, embodying the phenomena described in the foregoing paragraphs, is given in Fig. 1, in which part (a) has been plotted directly from the data sheets in the published report from the National Physical Laboratory, for an oil of kinematic viscosity 0.0001474—about 62 seconds Saybolt—flowing in a 3-in. drawn steel pipe. The friction head in feet per hundred feet of pipe is plotted against the velocity in feet per second, by the familiar method of logarithmic plotting—that is, not the quantities themselves but their logarithms are plotted against each other. The points are found to fall on straight lines, whose slopes are the exponents of the variables in the equations which express the relation of h and v ; for if m be the slope of the line and C its intercept on the axis of abscissas, then $\log h = m (\log v - C)$. Taking C as the logarithm of some constant A ,

$$\log h = m (\log v - \log A); \text{ or,}$$

$$h = \left(\frac{v}{A} \right)^m = K v^m \quad (3)$$

so that each of the three broken lines of which the graph is composed represents a condition of flow in which h varies as some power, m , of v . The lower part of the graph represents the region of steady flow, and the slope of the line is 1.0, confirming the statement that the variation in this region is linear, or as the first power. The upper part of the graph represents the region of eddy flow, where the slope of the line is 1.74, and the friction head varies as this power of the velocity. The intermediate line represents the region of uncertain flow, where the points as plotted do not suffice to determine the slope of the line, and where in fact successive experimental determinations cannot be made to agree. The line which has been drawn as the average locus of points in this region runs from the value of $\log v$ which makes $\frac{r \rho d}{\mu} = 2,050$ (Reynolds criterion) to that which makes it equal to 2,900; these values of R are mean values from all the experiments

FIG. 1. RELATION OF VELOCITY TO FRICTION HEAD

on which the report is based, and they make the slope of the line equal to 3.0, so that h in this region varies approximately as the cube of v . It must be remembered that the variation here really is indeterminate, the flow being apparently unstable. The matter is of little practical importance because the uncertainty extends only over the short range from the critical velocity to a velocity about 1.41 times as great; the important matter

⁴Phil. Trans. Royal Soc., vol. 174, p. 935 (1883); vol. 186A, p. 123 (1895).

is to know that the friction head will vary as the first power of the velocity below the point where $R = 2,050$, and as the 1.74 power above the point where $R = 2,900$.

In Reynolds' opinion, the fact that these changes occur suddenly instead of developing gradually indicates that the whole régime of steady flow is unstable. From this point of view we may suppose that when the break does come, the friction head increases in the erratic and rapid manner noted in order to gain the régime of eddy flow as quickly as possible; attaining this point, as we have seen, by the time the velocity has increased sufficiently to make $R = 2,900$.

CALCULATION OF FRICTION HEAD

We are now in possession of a crude method for calculating the friction loss of any liquid in pipes of smoothness equal to that of drawn piping, provided we can find means to determine the kinematic viscosity of

the liquid—that is, the ratio $\frac{\mu}{\rho}$, for substitution in the foregoing formulae. We can compute, from equation (2), the value of v_1 which makes $R = 2,050$. Then from equation (1) we can find the value of the corresponding h_1 , and we know that for all lower velocities the value of h decreases directly as the velocity, or

$$h_1/h_2 = v_2/v_1 \quad (4)$$

Next we may compute the value v_2 which makes $R = 2,900$, and we know that

$$h_2/h_1 = v_1^{1.74}/v_2^{1.74} \quad (5)$$

The same ratio of variation holds for velocities between v_1 and v_2 . Finally, for any higher velocity v , we know that

$$h/h_2 = v_2^{1.74}/v^{1.74} \quad (6)$$

This would indeed be a bungling method, and liable to error both from the magnification of slight inaccuracies in the work and from the fact that the last exponent does not continue equal to 1.74 for the very highest velocities, nor for great changes in roughness, although it is sensibly so for all cases of practical interest. But it is worth while to note the possibilities of this method because it really offers a more complete analysis of the problem than the simpler and more convenient process to be described later, on which the tables are based.

RELATIONS OF SAYBOLT TO KINEMATIC VISCOSITY

From what has been said about the determination of viscosity, it may be seen that any long pipe, even a pipe in industrial service, could be used as a viscosimeter if observations could be made on it with sufficient accuracy, the velocity being kept low enough to avoid eddying. For physical laboratory use this condition is obtained with tubes of capillary fineness, and correspondingly refined methods of observation; while in the commercial laboratory instruments are used which are somewhat simpler in construction, although based on the same principle, such as the Engler, Redwood and Saybolt Universal, the latter being the one most in use in the United States.

The Saybolt instrument consists essentially of a smooth vertical efflux tube, 1.225 cm. long and 0.1765 cm. in diameter, through which it is intended that steady or non-eddy flow shall take place. This tube is surmounted by a vertical cylindrical container, 2.975

cm. in diameter and about 9.7 cm. long, connected to the upper end of the efflux tube by a converging section about 1.575 cm. long. The upper container holds a little more than 70 c.c. and the whole is surrounded by a water bath to maintain a constant temperature of the liquid in the container. The determination consists of filling the container with the liquid under investigation, and letting 60 c.c. run out through the tube into a graduated vial, noting the time of flow required in seconds.

Referring to equation (1), we see that a constant average head, h , and constant values of r and l are assured by the construction of the instrument, and the time of flow of course is proportional to v ; consequently if the flow were truly steady, the kinematic

viscosity, $\frac{\mu}{\rho}$, would be truly proportional to the time of

flow or so-called Saybolt seconds. But the instrument is faulty, in that for liquids of low viscosity the flow is not steady, but eddying, so that the Saybolt seconds are no indication of true viscosity. There are also other sources of error, chief of which is the resistance to flow offered by the surface tension of the drop as it forms on the end of the efflux tube. The kinetic energy or velocity head of the flowing liquid also ought to be allowed for and subtracted from the total average head. The net effect of these and other inaccuracies of the method is to make the time of outflow for liquids of low viscosity enormously greater than it would be if the flow were steady, and entirely out of proportion to the true viscosity.

Prof. Flowers⁵ tells us that in designing the original Saybolt instrument it was intended that the length and diameter of the tube should be such as to assure the condition of steady flow for water, which was to be used as a standard. This may have been true of the form of the instrument first used, but it is not true of the present, called the Universal, instrument. For this the time of flow of water is about 31 seconds, while the errors above described are serious for all liquids up to those which have a Saybolt time of about 250 seconds. The comparison with water, therefore, should never be looked upon as having any relation to the true viscosity of another liquid, and is in no way an indication of the friction loss to be expected in handling that liquid in pipes. When the time of flow is above 250, however, the errors are not so serious and the Saybolt seconds vary almost exactly as the kinematic viscosity.

CALIBRATION OF SAYBOLT VISCOSIMETER

The only way, then, to get true viscosity readings from a Saybolt viscosimeter is to calibrate the instrument by the use of liquids of known viscosity previously determined by physical laboratory apparatus; and this calibration will apply only to the particular instrument for which it is made, because not all of these instruments are of accurately similar dimensions. To overcome this difficulty, the Bureau of Standards has published, in the work referred to, an account of an agreement with Mr. Saybolt whereby certain definite dimensions are hereafter to be used and considered as characterizing the standardized Saybolt Universal Viscosimeter; and the same paper gives the calibration of this instrument, by means of which the

⁵American Society for Testing Materials, *Proceedings*, vol. 14, 1914, p. 565.

FIG. 2. RELATION BETWEEN SAYBOLT SECONDS AND KINEMATIC VISCOSITIES

kinematic viscosity of a liquid may be known from its Saybolt seconds; thus providing us with a practical means of completing the method of equations (1), (4), (5) and (6) for computing pipe friction loss as a function of the kinematic viscosity.

In the publication of the Bureau of Standards, the calibration is given as an equation and also in the form of a table, the values being in c.g.s. units. In Fig. 2 of the present paper the table is put into graphic form, the values being converted to English units. The curve is used by entering with the Saybolt seconds, from which a conversion factor is found, by which the Saybolt seconds must be multiplied to give the kinematic viscosity.

It will be seen that this work is of the greatest value in investigations of the kind with which we are concerned. The determination by the Saybolt instrument is very easily made; the refiner or seller of mineral oils can always give the Saybolt viscosity at any temperature which the user may assume as governing his particular case. In developing the method for computing pipe friction loss and compiling the appended tables, this calibration has been assumed to apply to all Universal instruments. In making this assumption the fact is not lost sight of that it really applies only to a standardized instrument; but as the standard dimensions and calibration taken were the average for several instruments investigated, it is believed that the error will not be greater than is permissible in computations of liquid flow, and that the convenience and usefulness of having a definite and general means for calculating friction loss will justify the slight degree of approximation involved.

It has been stated above that the method of equations (1), (4), (5) and (6) was developed more for the sake of analyzing the nature of friction loss than as a rule to be followed in practical designing. A more convenient way of exhibiting the same results, although it does not show the fundamental relations of the variables so clearly, is given in the work of the National Physical Laboratory. These experiments were begun for the purpose of determining the frictional resistance of the atmosphere to the passage of an airplane body, the method used being the reverse process of passing air through smooth-walled pipes. The results obtained were so suggestive that the investigations were extended to include a study of water and of oil; then a second series of experiments on the friction resistance of fuel oils carried out for the British Admiralty gave similar results, and finally all available recorded researches on the subject of fluid friction were re-computed and recast in the same form, and were found to be consistent with the rest. The whole investigation covered the flow of air in pipes from 0.361 to 20.0 cm. diameter; of water from 0.361 to 28.5 cm.; and of oil from 3 to 5 in., over a very great range of velocities, all in smooth-drawn brass or steel pipes. The conclusion to which all this work led was that for equal values of $\frac{v \rho d}{\mu}$, values of the friction factor f are always equal in the well-known Fanning formula

$$h = f \frac{l v^2}{d 2g} \quad (7)$$

The curve of Fig. 3 is plotted with values of $\frac{v \rho d}{\mu}$ as abscissas and values of f as ordinates. No attempt

is made to state the relation in mathematical form; it is simply to be scaled from the curve as drawn.

The significance of this is that since for a given velocity and pipe diameter all liquids of equal kinematic viscosity have equal values of $\frac{v\rho d}{\mu}$ and consequently equal values of f , it follows that they have equal values of friction head h . But it has been shown that liquids of the same kinematic viscosity have equal Saybolt seconds; so that it must be concluded that liquids of equal Saybolt viscosity always have the same loss of friction head when flowing at the same velocity in the same pipe. This is a conclusion of very great interest and importance.

It has always seemed probable, from general considerations, that such a relation must exist, but apparently it never before was experimentally and satis-

find the value of f for the desired v and d from Fig. 3; completing the calculation of h by means of the Fanning equation (7). It was by this method that the tables given with this article were computed.

Partly as a matter of interest, and partly as a means of checking up and locating discrepancies, these tables were plotted by the logarithmic method of (a) Fig. 1, and one of the resulting diagrams is shown in (b) of the same figure for a Saybolt viscosity of 100, with pipe diameters of from 1 to 6 in. The plotted points fall very accurately on lines of slope 1.74 above the post-critical velocity, and on slopes of 3 and 1 in the two other régimes of lower velocities. The source of the breaks at critical and post-critical points is clearly seen in Fig. 3, for in that curve, which is the direct record of experiment, it is found that steady flow changes to uncertain flow at the Reynolds criterion,

FIG. 3. RELATION BETWEEN FRICTION FACTOR AND vd/ν

factorily demonstrated. From this fact it follows that if a series of experiments were conducted on the flow of liquids of conveniently varying Saybolt viscosities, the results would serve once and for all as a basis on which to calculate the friction losses of other liquids within the same Saybolt range. But with the aid of the Bureau of Standards calibration it becomes unnecessary actually to carry out such a set of experiments; for we may determine the kinematic viscosity, ν , directly from the instrument and Fig. 2, and then

$\frac{v\rho d}{\mu} = 2,050$, while uncertain flow changes again to the regular condition of eddy flow at the post-criterion, $\frac{v\rho d}{\mu} = 2,900$.

The appearance of the first two branches of the curve in Fig. 3 is so irregular as to require some explanation. In the experiments at the National Physical Laboratory, from which the curve was plotted, the method used was to observe all the quantities in equa-

tion (7), and solve for f . This was rational as long as the character of flow was of the regular eddy type, to which alone the equation applies. But the experimenters used the same process when the flow was steady and also when it was in the uncertain régime; so that they were then arbitrarily forcing their experimental values into an equation which does not properly present the facts. In this way they got the values of f shown in the first two branches of Fig. 3, which serve a legitimate purpose in illustrating the fundamental truth that friction loss depends on velocity, diameter and kinematic viscosity, but give an erroneous idea of the true relations of these factors. The same truth is expressed, with reference to the régime of steady flow, by equation (1), which shows equally well that friction loss depends on the factors mentioned, and shows the real nature of the relation; and as a matter of fact, if values of h be computed from equation (1) and then substituted in equation (7) to deduce values of f , these latter will lie exactly on the first branch of the curve in Fig. 3.

Equation (7) itself, although it is perhaps the most generally accepted statement of the law of hydraulic (eddy) flow, is quite likely to mislead the student unless he notes carefully the significance of the coefficient f . This coefficient is not constant, but varies with every variation of v or d . For use with formula (7) it is necessary to provide an extensive table of values of f , showing its changing value over the desired range of velocity and diameter. The general form of the equation gives the impression that friction loss varies as the square of the velocity, but that is not really the case; the variable coefficient f acts to reduce the computed value of h to what it would have been if the exponent of v had been written correctly, its true value being 1.74 for the drawn pipes under consideration, and about 1.80 for wrought and cast iron pipes of ordinary roughness. In the present case, for a constant kinematic viscosity, equation (7) could be written

$$h = F \frac{lv^{1.74}}{d} \quad (8)$$

in which F varies only with the diameter; or, the formula may be made general by expressing F as a function of d . This is the form which most recent experimenters have used for expressing their results. A formula established at the University of Texas for the flow of water at 68 deg. F. in clean iron pipes up to 3 in. diameter, with velocities up to 3 ft. per sec., was

$$h = 0.00685 \frac{v^{1.77}}{d^{1.75}} \quad (9)$$

where h = friction head in feet per foot and d = diameter in inches.

This formula has been used in connection with the present work for comparison of the results obtained by its use with those obtained from Fig. 3 and equation (7) for the case of water in drawn pipe, as an indication of the amount by which friction loss in wrought-iron pipe exceeds that in drawn pipe.

Equation (9) holds only for the limited range wherein the exponent of v remains constant; this exponent increases noticeably with great increase of velocity, but it remains sensibly constant throughout the working range of practical interest, so that the index relation, while not a complete statement of hydraulic law, serves as a satisfactory working rule.

(Part II will be published in a subsequent issue.)

Report on the Leather Section, Sixtieth Meeting, A.C.S.

IN THE absence of Dr. Marbaker the meeting was presided over by Dr. A. W. THOMAS, of Columbia University.

NATURE OF THE HIDE-TANNIN COMPOUND AND ITS BEARING UPON TANNIN ANALYSIS

This paper, by Dr. JOHN ARTHUR WILSON, disproves the contentions of the opponents of the new method of tannin analysis as outlined by Dr. Wilson before the American Leather Chemists Association in Atlantic City. In this previous paper comparative tests showed the official method of the American Leather Chemists Association to be greatly in error, exceeding 200 per cent for typical samples of gambier extract. The much higher percentages of tannin obtained by the A.L.C.A. method for every material examined were attributed to the formation of a readily hydrolyzable compound between the hide powder and a variable fraction of the non-tannins. The chief aim of the opposition in the A.L.C.A. was apparently to show that the low results obtained by the new methods were due to losses of tannin in the manipulation of the methods, but no readily conclusive evidence was offered in support of these contentions. The object of the present work was to investigate these points because they are of great importance not only to this new method but to the theory and practice of tanning itself.

Typical commercial tanning extracts have been chosen for examination ranging in properties from the extremes of gambier and sumac to those of hemlock and quebracho. Two mixtures have also been included, each consisting of a pair of extracts of very different nature.

Extract manufacturers often remove only about 80 per cent of the tannin from the raw materials because in order to get the last 20 per cent they have to extract a large proportion of undesirable non-tannins that would considerably lower the purity of their product. The raw materials used were extracted completely and therefore contain a higher ratio of non-tannin to tannin than the commercial extract, and this, as shown, would increase the error obtained by the American Leather Chemists Association extract.

The results of these experiments show conclusively that prolonged washing is quite without influence upon the values obtained for the per cent of tannin in various materials by the new methods; and, further, that tannin once combined with hide cannot be washed out by any amount of washing that would be practical. Thus the major contention of opponents of the new method is disproved.

It was further found that the non-tannins are capable of undergoing chemical change with the formation of substances capable of tanning. Just what chemical actions are involved in the conversion of non-tannins to tannins must remain a matter of speculation until more data are available. Oxidation, condensation and polymerization may all be involved. It is conceivable that gallic acid might be converted into digallic acid under suitable conditions, and it seems extremely likely that a polymerized form of digallic acid would have tanning properties. A detannized solution which gives no test for tannins can

be made to give a strong test merely by passing oxygen gas through it. Long exposure to air has a similar action. It is evident that the new method furnishes a valuable means of studying the conversion of non-tannins into tannins and might conceivably be applied to a study of the formation of tannins in nature and to the aging of barks.

Experiments were further carried on to show the effect of the time factor in tanning and the aging of leather.

We feel justified in recommending that the new method, or some modification of it, be adopted as a standard to replace the present official method. One modification of the new method for routine control work is to tan the hide powder as usual, transfer it to an alundum thimble, wash it by means of a mechanical arrangement and then dry and weigh it, the increase in weight of the dry hide powder being taken as tannin. No doubt other modifications will suggest themselves as the work proceeds, but the saving of time in the A.L.C.A. method is not sufficient compensation for the errors involved.

Summarizing, tannin once combined with hide cannot be removed to an appreciable extent by any amount of washing that would be practical. It has been discovered that chemical changes are produced in the tan liquor by boiling and evaporating whereby certain non-tannins are converted into substances capable of tanning. Such changes can be followed quantitatively by means of the author's new method of tannin analysis, but not by the official method of the American Leather Chemists Association. The new method gives results which agree closely with tanning practice, whereas the A.L.C.A. method was found to be greatly in error. It is recommended that the new method be adopted as a standard.

THE MECHANISM OF BATING

Dr. JOHN ARTHUR WILSON also read a paper on "The Mechanism of Bating." The curious process of bating, so little known because of its secret origin, is at least some centuries old. After the skins are taken from the lime liquors, unhaired and washed, they are plump and rubbery, a condition not particularly suitable for putting them directly into tan liquors. The object of bating is to prepare the unhaired skins for tanning, and originally consisted in keeping them in a warm infusion of the dung of dogs or fowls until all plumpness had disappeared and the skins had become so soft as to retain the impression of thumb and finger when pinched and sufficiently porous to permit the passage of air under slight pressure. As a result of investigation the use of dung as a bating material has been replaced in many tanneries by the mixture of ammonium chloride and pancreatin.

The question arises as to whether bating is not simply a means of bringing the skins into a condition of minimum swelling, especially since such a condition would give the skins those physical properties which are widely accepted as indicative of properly bated skins. If this is so it would reduce bating to perhaps the simplest of the tannery processes.

Experiments show that a pure solution of ammonium chloride, of the same concentration and alkalinity as the bate liquor, produces practically the same degree of swelling. Another test was made by comparing the action of ammonium chloride alone with that of a commercial bate, supposedly containing ammonium

chloride and pancreatin. This test indicated either that pancreatin was of no practical benefit or else that the commercial bate was deficient in enzymes.

What Rosenthal proved was merely that bating removed almost to completion certain nitrogenous matter from the limed skin, but whether this was elastin or hide substance which had previously been attacked by lime appears open to question. Other investigators concluded that elastin is present only in the grain membrane and that it must be digested before tanning to produce a satisfactory grain, but that the bating of the skin under the grain is not only unnecessary but often undesirable.

We have made experiments to determine definitely the question of the removal of elastin in the bating process by means of photomicrographs of cross-sections of the skin taken before and after bating. Fibers were stained with magenta to make the elastin fibers discernible. Microscopic examination of a piece of skin from the trypsin liquor used showed that practically all of the elastin had been removed, while on a piece treated with ammonium chloride only the elastin was left apparently unaltered. The view of Seymour-Jones that the main body of skin contains no elastin was substantiated.

The value of removing elastin from skins must depend to some extent upon the particular properties desired in the leather. The mechanism of bating evidently consists of two distinct parts: (1) Reducing limed skin to a condition of minimum swelling and (2) digesting the elastin fibers present in the outer layer of the skin.

NITROGENOUS FERTILIZER FROM TANNERY WASTE SULPHIDE LIQUORS

D. H. KADISH presented a paper on "A New Method for the Recovery of Nitrogenous Fertilizer Material From Tannery Waste Sulphide Liquors."

There are two methods of liming—namely, the still and paddle process and the sodium sulphide process. Both methods give about the same result in the finished leather, although the second method is not so foolproof as liming. In the first method hair is recovered, but in the second method it is dissolved. This hair is at present sold on the market for a price that makes it worth while saving, while there is a question of the disposal of liquor in the second method. At the present time this is turned into the sewer, but we believe it may be recovered economically.

The method designed for this recovery consists of a tank into which the waste sulphide liquor is poured and from which it is drawn into an orifice box and subsequently at a pipe connection meets with acids drawn from a similar tank, usually sulphuric or liquor made from niter cake. After the two have joined in the pipe the flow is carried on to a settling tank which contains a slight excess of acid. This settling tank is covered over and has an exhaust port at the top for recovering the H_2S and carrying it to a tower where it may be made into sodium sulphide and re-used. The recovery of sodium sulphide is from 50 to 75 per cent of that employed in the tanning.

At the bottom of the settling tank the liquor is finally drawn off, leaving a solid material in the tank which consists of colloids packed down of their own weight. This colloid matter, being changed to trisulphides, is shoveled out like dirt. It has a maximum

water content of 10 per cent and may be sold on the market for fertilizer. The plant may be erected to have a capacity of from 3,000 to 30,000 gal. of waste liquor per hour.

The operation of the plant shows that 39 lb. of fertilizer may be recovered per 100 lb. of liquor. This fertilizer has an average content of 12 per cent ammonia and sells at the rate of about \$72 per ton. The operation cost is slight. Analysis of the fertilizer showed 11.04 per cent nitrogen or 13.18 per cent ammonia. This plant has been erected at the Pfister & Vogel tannery at Milwaukee and the process is covered by U. S. Patents 1,269,189 and 1,298,960.

CHEMICAL CONTROL OF THE TANNERY

While the paper, "Chemical Control of the Tannery," by F. C. ORTHMANN, came from one of the finest leather laboratories in the United States, it was a mere outline of methods that might well be employed in many laboratories. It is generally a method of keeping records and abstracts for heads of departments with loose-leaf binders, including the analysis of all compounds that are purchased or sold from the tanneries.

SWELLING AND FALLING OFF OF WHITE HIDE IN VEGETABLE TAN LIQUORS

"The Swelling and Falling Off of White Hide in Vegetable Tan Liquors," by G. D. McLAUGHLIN and R. E. PORTER, was a paper in which the authors reported an exhaustive set of tests, plotting ten sets of curves showing the action of a hide with lactic, acetic, pyrogallic and gallic acids, together with the calcium compounds of same.

The result showed that vegetable tanning liquor may not be regarded as an entity and that lactic acid is a natural reagent. This latter is good to use in the tannery and the specific amount should be worked out for local conditions. Acetic acid is dangerous in too great quantities.

Excess gallic acid gives a thin, poorly tanned leather.

Lactic acid is particularly good for a mellow in a new tannery starting into operation. The methods of tests have shown that they are good for judging astringency. The samples used were taken from a uniform rectangle cut just above the tail of the hide.

In the discussion of this paper SIGMUND SAXE, of New York, stated that it was one of the best papers he had ever heard on the subject.

THE INFLUENCE OF NON-TANNIN ACIDS ON THE TANNIN CONTENT OF TAN LIQUORS

ALAN A. CLAFLIN made an exhaustive set of tests on chestnut and quebracho extracts and gave the results of his experiments in a paper entitled "The Influence of Non-Tannin Acids on the Tannin Content of Tan Liquors." He expects to continue to cover a series of other extracts. Experiments were presented on the whole series in a half-way state of the work. The author entered a plea for other chemists to also take up this work.

The experiments were based on the action of non-tannin acids—i. e., that sulphuric acid will precipitate tannin and fermentation will cause a loss of tannin. Dilute sulphuric acid causes a heavy precipitate which is not analyzed in the literature at present available. Fermentation changes tannin to gallic acid.

The theory is that tannin anhydrides are formed and analyses were made before and after the addition of the non-tannin acids to the extract solution. The A.L.C.A. method of analysis was used in the first set of experiments. The results of the work with the extracts were tabulated to show the solids and insoluble matter with no acid, with normal lactic acid, with acetic, sulphuric and hydrochloric acid.

The discussion brought out the fact that the results were not surprising, because so-called spruce or ligno-sulphonic acid from the paper mills gives a clear solution on testing.

THE EFFECT OF CONCENTRATION OF CHROME LIQUOR UPON THE ADSORPTION OF ITS CONSTITUENTS BY HIDE SUBSTANCE

ARTHUR W. THOMAS and MARGARET W. KELLY presented a paper on "The Effect of Concentration of Chrome Liquor Upon the Adsorption of Its Constituents by Hide Substance," which is a continuation of the work that Dr. Thomas is carrying on in colloids at the Research Laboratory of Pure Chemistry, Columbia University. This work is being carried out under the funds of the Gallun Co., and all results of work are to be made available to the public. This is just another example of the attitude of a generous manufacturer in making public all research carried out under funds furnished by the company. Such a spirit will go far in the development of our leather industries.

The experiments reported in this paper were conducted to test whether the adsorption from various liquors containing 0.038 to 6.640 g. of chromic oxide per 100 c.c. of liquor, insuring a maximum at concentration of 1.5 to 2.0 g. of chromic oxide per 100 c.c. would not have shown a point of minimum beyond which increasing concentration would have caused greater fixation of chrome if the liquors had been carried to higher concentration. The results of the experiments are shown in Tables I and II.

TABLE I

Number	Gms. Cr ₂ O ₃ per 100 c.c. of Liquor Before Adsorption	Composition of Chromed Hide Powder			
		Protein per Cent	Cr ₂ O ₃ per Cent	SO ₃ per Cent	Ash, per Cent
1	0.0363	98.19	1.30	1.09	1.59
2	0.2881	83.70	7.86	6.07	8.84
3	0.7738	76.63	10.58	8.18	11.82
4	1.5526	75.90	10.85	8.67	12.12
5	3.0853	78.43	10.25	8.89	11.23
6	4.8073	80.17	9.36	8.25	10.09
7	7.3070	83.87	7.85	7.21	8.62
8	9.7267	84.83	5.92	6.12	6.50
9	12.175	89.77	3.86	5.19	4.89
10	14.754	90.67	2.35	4.48	3.82

TABLE II. COMPOSITION OF LIQUORS AFTER ADSORPTION

Number	Grams Cr ₂ O ₃ in 100 c.c.
1	0.0096
2	0.0510
3	0.4464
4	1.2586
5	2.8577
6	4.7587
7	7.4350
8	10.0215
9	12.5820
10	17.4000

The values obtained show removal of hydrogen ion from the liquors up to the solution of concentration of 7.4 g. of chromic oxide per 100 c.c., beyond which the curves join and run together, indicating that if hydrogen ion was removed it was so slight that the buffer action of the chromic sulphate could take care of it.

The authors concluded that on experience to date the reaction between chromic sulphate solutions and hide substance is chemical and not physical. If the adsorption were a simple physical process—namely, merely a partition of the chromic oxide and sulphuric acid between the solid hide substance phase and the solution phase—the curve should follow Henry's law, $C_1 = kC_2$, which is parabolic in shape. As the experiments show, the curve begins to slope downward after the concentration of the liquor exceeds approximately 25 grams of chromic oxide per liter in the solution of the composition $\text{Cr}(\text{OH})\text{SO}_4$.

DYES AS USED IN THE LEATHER TRADE

"Dyes as Used in the Leather Trade," by P. R. ROBERTS, was a plea that the tannery chemists test all dyestuffs before purchasing with regard to reduction of strength of the leather, retardation of penetration or action to generally deteriorate. The specific gravity of the various dyes entering into mixtures should run even because of possible segregation in the mill. Every tannery should have a dye laboratory and not use a mixture that will settle out compounds of different specific gravities. The dye chemists of the tanneries should co-operate with the color house for securing proper colors in the dyeing of leather.

DETERMINATION OF HYDROCHLORIC ACID AND NEUTRAL CHLORIDES IN LEATHER

"The Determination of Hydrochloric Acid and Neutral Chlorides in Leather" was discussed by ARTHUR W. THOMAS and ALEXANDER FRIEDEN. The extent to which sulphuric acid in leather will rot the finished product is an important one to vegetable tanners, but sulphuric acid is only one of the mineral acids that may be present, and if the work is to be complete hydrochloric acid must be included. The method of analysis depends on the principle that divalent ions are adsorbed more readily than the trivalent ions. Ammonium and sodium phosphate was used in making the test, while ethyl alcohol was used as a solvent for the chlorides.

The chlorides were precipitated with silver nitrate with a slight extract of nitric acid to wash down the organic content. The nitric acid was present in sufficient quantity to prevent the forming of silver phosphate and did not impair the accuracy of the method. It was obvious from the experiments carried out that the water extraction could not be used for separation of neutral chloride from acid chloride in leather.

Hence, in our opinion, acids are combined chemically with collagen provided they come in contact with the collagen before all the free valences of the collagen are satisfied by tanning agents and the removal of an acid from leather by hot water is due to hydrolysis. It is evident, then, that the hydrochloric acid collagen compound is hydrolyzed much more readily than the sulphuric acid collagen compounds.

The results obtained by the methods employed were compared with the amounts of chloride obtained by the method of determination by ashing the leather soaked with sodium carbonate solution and covered with dry sodium carbonate. The ashing was conducted at as low a heat as possible and the amount of chloride present in the sodium carbonate was determined and correction applied in each case.

The total chloride found by ashing at low heat in the presence of alkali is in every case higher than

the total chloride found by the phosphate digestion. This is due to the chlorine present as a part of the protein molecule, or present in the leather in forms other than chloride.

An objection might be raised for the use of ethyl alcohol, which is difficult to obtain in quantity on account of restrictions imposed due to the new law. We see no reason, however, why denatured alcohol that has been twice distilled, first over phosphoric acid and then over alkali, would not serve just as well as pure ethyl alcohol.

"Comment on Wilson's and Kern's Recent Contribution to the Knowledge of Vegetable Tanning Agents" was given by A. W. THOMAS. In a recent work by Wilson and Kern, which showed large errors obtaining by use of the official method of the American Leather Chemists Association, these errors were shown as follows, in order of the greatest amount of non-tannins:

	Per Cent		Per Cent
Gambier	220	Larch bark	89
Osage orange	198	Oak bark	88
Sumac	166	Hemlock bark	63
Chestnut wood	117	Quebracho	43

Since tannins react with gelatine to form insoluble compounds while non-tans do not so react with gelatine, it was considered that a comparative measure of the content of non-tans in extracts could be indicated by their diffusion through gelatine jelly, the extent of the diffusion being measured by the formation of a black color. The results of experiments along these lines were as follows:

DIFFUSIONS OF NON-TANS THROUGH GELATINE JELLY

Material	48 Hr. Mm.	96 Hr. Mm.	144 Hr. Mm.	216 Hr. Mm.
Sumac	17 3	22 3	27 0	32 5
Gambier	13 8	18 0	22 0	26 0
Chestnut wood	12 0	17 8	20 0	23 8
Oak bark	9 0	13 0	15 2	18 3
Larch bark	9 0	12 0	14 5	16 0
Hemlock bark	6 0	8 3	9 5	12 0
Osage orange	4 3	4 8	5 0	6 0
Quebracho	3 8	4 8	5 8	7 3

The order of diffusion of the non-tans was, therefore; sumac > gambier > chestnut wood > oak bark > larch bark > hemlock bark > quebracho > osage orange.

With the exception of osage orange, the order found here is similar to the order given by Wilson and Kern. This is, therefore, confirmatory of the work which has been previously mentioned.

BUSINESS MEETING

At the close of the technical papers, the Section held its annual business meeting, and elected Dr. John Arthur Wilson as Chairman and G. D. McLaughlin as Secretary of the Section. It was further voted that the Leather Section will not meet at the spring meeting of the Society in Rochester, but will hold one large meeting in New York next September.

Colored Plasters

The investigation of colored plasters by the Bureau of Standards has been completed. It has been found possible to make colored wall plasters of any desired color or texture by use of dyed wood fiber in gypsum plaster. Panels of this material have been submitted to the Gypsum Industries Association in Chicago, and a publication on the subject is now being prepared.

Manufacture of Rich Copper:Aluminum Alloys or Hardeners

Describing the Methods in Use in Aluminum Foundries of the United States for Manufacturing Rich Alloys of Copper and Aluminum, and Details of Experiments Carried Out for the Purpose of Comparing Different Methods

By ROBERT J. ANDERSON

THE use of rich copper:aluminum alloys for introducing copper into aluminum in the manufacture of No. 12 alloy or similar other light aluminum: copper alloys is an old practice, and it dates back to the early days of aluminum founding. As has been pointed out¹ by the present writer, copper may be alloyed with aluminum in making up alloys for sand casting by two distinct methods; (1) by adding solid copper to liquid aluminum, and (2) by charging a rich copper:aluminum alloy with the aluminum. The majority of the aluminum foundries in the United States prefer to make up heats of No. 12 alloy by using a rich alloy containing about 50.0 per cent copper and 50.0 per cent aluminum. This rich alloy is referred to in foundry parlance as "hardener," "rich alloy" or "50:50," and for brevity it will be referred to in this paper as 50:50 alloy. Another alloy preferred by a few is the eutectic containing 33.0 per cent copper and 67.0 per cent aluminum. A rich alloy containing 60.0 per cent copper and 40.0 per cent aluminum has also been suggested for the same purpose, but it has probably not been used commercially.

In the metallurgy of aluminum alloys, rich alloys are employed because they melt at temperatures lower than aluminum and, further, because they are brittle. The latter property permits them to be broken readily into small pieces, and thus to be weighed accurately. Originally, the rich alloys were used because they were a convenience, but under the conditions of fast practice in the large aluminum foundries of the United States, their use has become a necessity. Methods for preparing the rich copper:aluminum alloys vary somewhat in different foundries, but experience indicates that certain details in manufacture must be followed closely in order to avoid heavy dross losses. Whether the 33:67 or the 50:50 alloy is made is not a matter of a great deal of importance from the metallurgical standpoint, since the fundamental principles involved are the same for either alloy.

METHODS USED COMMERCIALY

There are three distinct methods in use for the manufacture of rich copper:aluminum alloys (50:50), of which the second is the most generally used; the two other methods are employed mainly in small foundries for making small lots of hardener for their own consumption. These methods are essentially carried out as follows: (1) By adding solid aluminum to liquid copper; (2) by adding liquid copper to liquid aluminum; and (3) by adding solid copper to liquid aluminum. The alloys may also be prepared by pouring liquid aluminum into liquid copper, but the opportunity for

segregation is greatly increased in this way, and this is, in fact, a decidedly inadvisable method.

SOLID ALUMINUM TO LIQUID COPPER

Rich alloys, such as 50:50 alloy, are made in a few foundries by the addition of solid aluminum to liquid copper; this is, however, not a desirable procedure. One way of carrying out this method in the foundry is to melt the copper in a crucible and then add small amounts of cold aluminum from time to time with stirring until the requisite amount of aluminum has been put in. Too much aluminum cannot be added at one time, unless the copper is greatly superheated, or the entire melt will freeze. Ordinarily, it is necessary to maintain the temperature of the copper in the crucible by holding the pot in the furnace with the burners on. This is wasteful of fuel, and the method is slow and conducive to heavy dross losses. It is still used, however, in some small foundries in spite of its very obvious disadvantages.

LIQUID COPPER TO LIQUID ALUMINUM

The most favored method for making rich alloys consists in melting the copper and aluminum separately and then pouring the liquid copper into the liquid aluminum. The resultant alloy is vigorously stirred to insure thorough alloying and prevent segregation; the alloy is then ingoted in the form of pigs of various convenient sizes from 10 to 60 lb. or more. Where large lots are made at one time, it is good practice after melting the metals to pour the liquid aluminum into a large mixing vessel or container and then pour the copper into the aluminum. For convenience, the mixing vessel should be located near the furnace used for melting the copper.

As it is important to keep the temperature of the resultant alloy as low as possible so as to avoid heavy dross losses, the liquid aluminum should be chilled by adding cold aluminum ingot or notch bar. Thus only part of the aluminum to be used should be melted—say about two-thirds—and the remainder should be retained for use in lowering the temperature of the alloy during the time the copper is being put in and afterward.

It requires considerable skill to maintain the resultant alloy at a low temperature because of the considerable rise in temperature which takes place when liquid copper is added to liquid aluminum.² The temperature rise is conducive to heavy dross losses, and it is best counteracted by the addition of sufficient cold aluminum in amount depending upon the temperatures of the liquid aluminum and liquid copper. Experience, together

with pyrometric measurements of the temperatures, will best indicate the correct procedure.

SOLID COPPER TO LIQUID ALUMINUM

This method for preparing rich alloys is similar to the method used for preparing No. 12 alloy by direct additions of solid copper to liquid aluminum. It is not used to any extent because foundries which prefer to add solid copper to liquid aluminum in the manufacture of No. 12 alloy do not use rich alloys. However, a few instances of the commercial use of this method have been reported. The method is carried out simply by melting the aluminum and then adding small amounts of light copper (sheet, punchings or other scrap) from time to time until the required amount of copper has been put in. After each addition of copper, the melt is stirred until the copper goes into solution. Dross losses are normally high in this method; furthermore, it is slow and not suitable for making large lots of 50:50 alloy.

LIQUID ALUMINUM TO LIQUID COPPER

No instances of pouring liquid aluminum into liquid copper as a commercial practice for the manufacture of 50:50 alloy have been reported, although this has been tried. A modification of this method is used, however, in some small foundries for making up small lots. In this modification, the copper is melted in a crucible, preferably in a stationary gas- or oil-fired furnace. A small notch bar of aluminum is held by tongs in the mouth of the furnace so that it gradually melts; as it melts, drops of liquid aluminum fall into the liquid copper. The resultant alloy is stirred from time to time until all the aluminum has been put in. This is a slow and expensive method, and conducive to high oxidation losses.

COMPARISON OF THE METHODS

In the commercial manufacture of rich alloys of copper and aluminum, the consensus of opinion among the larger foundries is that liquid copper should be poured into liquid aluminum, with an endeavor at the same time to keep the temperature low by chilling the melt with additions of cold aluminum ingot; this should be accompanied by vigorous stirring. Where solid aluminum is added to liquid copper, there is danger of explosions from absorbed water in the aluminum, and in this method the aluminum should be preheated so as to drive out any water. This can be done by placing the notch bars on top of the furnace while the copper is melting. This method is conducive to heavy dross losses because of the high temperatures and the thermit reaction if much copper oxide is present (as there usually will be unless the copper is melted under charcoal). This method is also slow and wasteful of fuel; only small amounts of cold aluminum can be added at a time, otherwise the whole melt will freeze. In general, this method is undesirable and but little used.

When liquid copper is poured into liquid aluminum, the temperature of the resultant alloy may become high because of the normal heat of formation of the alloy, and further, because of the thermit reaction which usually takes place. This is the only serious disadvantage in thus making the rich alloys, but it may be largely minimized by keeping the temperatures low by adding cold aluminum. This method is, in fact, the standard method for the manufacture of 50:50 alloy

FIGS. 1 TO 4.

Fig. 1—Eutectic alloy of copper and aluminum (33Cu : 67Al); etched NaOH; $\times 130$. Fig. 2—Eutectic alloy of copper and aluminum; etched $\text{Fe}_2(\text{SO}_4)_3$; $\times 230$. on a large scale, and while it is suitable for making both large and small lots, the method of adding solid copper to liquid aluminum may be preferable for small lots, say about 100 lb. Comparative figures as to dross losses for the various methods will be given later.

PROPERTIES OF THE RICH ALLOYS

Alloys containing 33 : 67, 50 : 50, and 60 : 40 copper : aluminum are all white in color, similar to aluminum, but the fractures are coarsely crystalline and bright. These alloys are all brittle, but the excessive brittleness diminishes with increasing aluminum content; thus, the 33 : 67 alloy is not so brittle as the 50 : 50 alloy, but the 60 : 40 alloy breaks readily if dropped on the floor. The 50 : 50 alloy is sufficiently brittle for all practical purposes, and if the rich alloys are too brittle, they powder excessively on breaking, thus causing dusting losses. Typical microstructures of these several alloys are shown in Figs. 1 to 4. The characteristic acicular structure formed when 50 : 50 alloy freezes uninterruptedly is shown in Fig. 5; the large interlocking crystals are conducive to brittleness, and this characteristic, together with the actual brittleness of the compound CuAl_2 , makes the alloy easy to break.

The eutectic alloy (33Cu : 67Al) melts at 540 deg. C., the 50 : 50 alloy at 575 deg. C. and the 60 : 40 alloy at 658 deg. C., practically the same temperature as aluminum.

EXPERIMENTS WITH RICH ALLOYS

In foundry practice, the rich alloys used for introducing copper into aluminum in the manufacture of No. 12 alloy and other such alloys include the 33 : 67 and 50 : 50 copper : aluminum alloys. The preparation of these rich alloys, as well as the 60 : 40 alloy, was studied in connection with the present investigation. A rich alloy containing 60.0 per cent copper and 40.0 per cent aluminum is very brittle, and it melts at about the same temperature as aluminum. In using this alloy, less of

* Solid metal temperatures are taken as room temperature - i. e., 25 deg. C.

† The figures indicate the observed highest temperatures; higher temperatures may have been attained, but they were not observed.

‡ Based on the assumption that dross is equivalent to Al_2O_3 , containing about 53.0 per cent aluminum.

§ The copper-melting furnace consumed 110.0 cu. ft. per min., and the aluminum-melting furnace 105.0 cu. ft. per min.; in some cases additional gas was used in addition to that required for melting.

¶ Based on gas at \$0.30 per 1,000 cu. ft.

it is required to make up a heat of No. 12 alloy than when using either of the two other rich alloys. For these reasons, the preparation of the 60:40 alloy was also investigated.

The metals were melted in gas-fired crucible furnaces, using natural gas as the fuel and plumbago-clay crucibles. The resultant liquid alloys were stirred with an iron rod from which any oxide was carefully scraped after using. The alloys were poured into small pigs weighing from 4 to 6 lb. each. Higher temperatures were taken with a platinum thermocouple protected by a quartz tube; and the lower temperatures were taken with a Wilson-Maeulen "pyod," using an indicating portable meter. The materials employed consisted of heavy copper clippings, light copper punchings and aluminum ingot of the analysis given in the subjoined table:

Material	Cu	Elements, per cent		
		Fe	Si	Al*
Aluminum ingot	0.25	0.39	0.31	99.05
Light copper punchings	99.89			
Heavy copper clippings	99.92			

* Aluminum, by difference.

The heavy copper used in experiments A-1, A-2, B-1, B-2, C-1 and C-2 was in the form of heavy clippings about $\frac{1}{4}$ to 1 in. thick. The light copper used in experiments A-3, B-3 and C-3 was in the form of light

punchings and clippings about 16 to 18 gage. The cold materials were charged into hot crucibles at a mean temperature of 600 deg. C., but this is an approximate mean temperature, as the variations were from 400 to 700 deg. C.

It required, on the average, 27 min. to heat a cold crucible to 600 deg. C., or a metered gas consumption of 2,800 to 2,900 cu. ft. The experiments are described in considerable detail below and are summarized in Table I.

33:67 COPPER:ALUMINUM ALLOY

This alloy was prepared by the three different methods mentioned above.

Experiment A-1. In this experiment, solid aluminum was added to liquid copper so as to make the desired alloy.

Experiment A-2. In this case, liquid copper was poured into liquid aluminum.

Charged copper into a hot crucible at 600 deg. C., lb.	8.25
Time required to melt the copper, min.	28.0
Gas consumption, cu ft.	3.080
Temperature of the copper at the time it was poured into the liquid aluminum, deg. C.	1,125
Charged aluminum (in a separate crucible) at 600 deg. C., lb.	16.75
Time required to melt the aluminum, min.	27.0
Gas consumption, cu ft.	2.835
Temperature of the aluminum at the time the copper was poured in, deg. C.	880
Highest temperature of the resultant alloy, deg. C.	1,065
Total gas consumption, cu ft.	5.915
Poured into pigs at, deg. C.	1,040
Weight of pigs poured, lb.	24.15
Weight of dross recovered, lb.	0.65
Shrinkage, lb.	0.20
Loss of metal due to oxidation and shrinkage, per cent.	3.4

Experiment A-3. Solid copper was added to liquid aluminum in this experiment in order to produce the desired alloy.

Charged aluminum into a hot crucible at 600 deg. C., lb.	16.75
Time required to melt the aluminum, min.	26.0
Gas consumption, cu ft.	2.730
Temperature of the aluminum at the time the first addition of copper was made, deg. C.	820
Charged copper in small amounts every few minutes during 20 minutes, lb.	8.25
Highest temperature of the alloy, deg. C.	925
Total gas consumption, cu ft.	2,730
Poured into pigs at, deg. C.	874
Weight of pigs poured, lb.	23.55
Weight of dross recovered, lb.	1.15
Shrinkage, lb.	0.30
Loss due to oxidation and shrinkage, per cent.	5.8

50:50 COPPER:ALUMINUM ALLOY

This alloy was made under the same conditions and by the different methods described above for the 33:67 alloy—i.e., by adding solid aluminum to liquid copper, by adding liquid copper to liquid aluminum and by adding solid copper to liquid aluminum.

Experiment B-1. In this experiment solid aluminum was added to liquid copper so as to make the desired alloy.

Charged copper into a hot crucible at 600 deg. C., lb.	12.50
Time required to melt the copper, min.	38.0
Gas consumption, cu ft.	4.180
Temperature of the copper at the time the first aluminum addition was made, deg. C.	1,120
Charged aluminum every few minutes during 20 minutes, lb.	12.5
Temperature of the alloy after an addition of 2.0 pounds solid aluminum, deg. C.	1,225
Temperature rise, deg. C.	105
Final temperature of the alloy, deg. C.	685
Total gas consumption, cu ft.	4,730
Poured into pigs at, deg. C.	677
Weight of pigs poured, lb.	23.75
Weight of dross recovered, lb.	1.00
Shrinkage, lb.	0.25
Loss due to oxidation and shrinkage, per cent.	5.0

Experiment B-2. Here, liquid copper was poured into liquid aluminum.

Charged copper into a hot crucible at 600 deg. C., lb.	12.5
Time required to melt the copper, min.	40.0
Gas consumption, cu ft.	4,400
Temperature of the copper at the time it was poured into the aluminum, deg. C.	1,203
Charged aluminum into a hot crucible at 600 deg. C., lb.	12.5
Time required to melt the aluminum, min.	26.0
Gas consumption, cu ft.	2,730
Temperature of the aluminum at the time the copper was poured, deg. C.	705
Highest temperature of the resultant alloy, deg. C.	1,085
Total gas consumption, cu ft.	7,130
Poured into pigs at, deg. C.	1,061
Weight of pigs poured, lb.	23.50
Weight of dross recovered, lb.	1.00
Shrinkage, lb.	0.5
Loss due to oxidation and shrinkage, per cent.	6.0

Experiment B-3. Solid copper was added to liquid aluminum in this experiment.

Charged aluminum into a hot crucible at 600 deg. C., lb.	12.5
Time required to melt the aluminum, min.	24.0
Gas consumption, cu ft.	2,520
Temperature of the aluminum at the time the first copper addition was made, deg. C.	690
Charged copper every few minutes during 20 minutes, lb.	12.5
Highest temperature of the alloy, deg. C.	906
Total gas consumption, cu ft.	3,145
Poured into pigs at, deg. C.	887
Weight of pigs poured, lb.	22.25
Weight of dross recovered, lb.	2.25
Shrinkage, lb.	0.5
Loss due to oxidation and shrinkage, per cent.	11.0

Experiment B-4. In this experiment copper was melted under a charcoal cover to prevent oxidation, and solid aluminum was then added. The temperature rise was observed.

Charged copper, lb.	10.0
Temperature of the copper at the time the aluminum was added, deg. C.	1,105
Charged solid aluminum, lb.	2.5
Temperature of the resultant alloy after the aluminum had gone into solution, deg. C.	1,220
Temperature rise, deg. C.	115

Experiment B-5. In this experiment a heat of 50:50 alloy was made in an electric furnace (Baily type), by adding solid aluminum to liquid copper.

Charged copper punchings into an electric furnace at 1,020 deg. C., lb.	50.0
Time required to melt the copper, min.	60.0
Power consumption, kw-hr.	52.0
Temperature of the copper at the time the first aluminum addition was made, deg. C.	1,050
Charged solid aluminum every few minutes during 60 minutes, lb.	50.0
Final temperature of the alloy, deg. C.	965
Total power consumption, kw-hr.	114
Poured into pigs at, deg. C.	800
Weight of pigs poured, lb.	91.5
Weight of dross recovered, lb.	14.0
Shrinkage	Gain
Loss due to oxidation and shrinkage, per cent.	8.5

60:40 COPPER:ALUMINUM ALLOY

This alloy was made by the methods mentioned above for the 33:67 alloy.

Experiment C-1. In this experiment solid aluminum was added to liquid copper so as to make the desired alloy.

Charged copper into a hot crucible at 600 deg. C., lb.	15.0
Time required to melt the copper, min.	42.0
Gas consumption, cu ft.	4,620
Temperature of the copper at the time the first aluminum addition was made, deg. C.	1,170
Charged aluminum every few minutes during 20 minutes, lb.	10.0
Temperature of the resultant alloy after adding 2.0 pounds of aluminum, deg. C.	1,278
Temperature change, deg. C.	108
Final temperature of the alloy, deg. C.	860
Total gas consumption, cu ft.	4,620
Poured into pigs at, deg. C.	842
Weight of pigs poured, lb.	22.60
Weight of dross recovered, lb.	2.00
Shrinkage, lb.	0.40
Loss due to oxidation and shrinkage, per cent.	9.6

Experiment C-2. Here, liquid copper was poured into liquid aluminum.

Charged copper into a hot crucible at 600 deg. C., lb.	15.0
Time required to melt the copper, min.	43.0
Gas consumption, cu ft.	4,730
Temperature of the copper at the time it was poured into the aluminum, deg. C.	1,205
Charged aluminum into a hot crucible at 600 deg. C., lb.	10.0
Time required to melt the aluminum, min.	21.0
Gas consumption, cu ft.	2,205
Temperature of the aluminum at the time the copper was poured in, deg. C.	750
Highest temperature of the resultant alloy, deg. C.	1,256
Total gas consumption, cu ft.	6,935
Poured into pigs at, deg. C.	1,190
Weight of pigs poured, lb.	23.50
Weight of dross recovered, lb.	1.00
Shrinkage, lb.	0.50
Loss due to oxidation and shrinkage, per cent.	6.0

Experiment C-3. Solid copper was added to liquid aluminum in this experiment.

Charged aluminum into a hot crucible at 600 deg. C., lb.	10.0
Time required to melt the aluminum, min.	22.0
Gas consumption, cu ft.	2,310
Temperature of the aluminum at the time the first copper addition was made, deg. C.	783
Charged copper every few minutes during 35 minutes, lb.	15.0
Highest temperature of the resultant alloy, deg. C.	855
Final temperature of the alloy, deg. C.	809
Poured into pigs at, deg. C.	787
Weight of pigs poured, lb.	22.15
Weight of dross recovered, lb.	2.55
Shrinkage, lb.	0.30
Loss due to oxidation and shrinkage, per cent.	11.4

Experiment C-4. An experiment was made in the preparation of the 60:40 alloy for the purpose of observing the temperature changes on adding successive amounts of cold solid copper to liquid aluminum.

Charged aluminum, lb. 10 0
 Temperature of the aluminum at the time of the first copper addition, deg. C. 785

TEMPERATURE CHANGES	
Additions	Temperature Deg. C.
Original melt.	785
Added 2 lb. Cu	820
Added 2 lb. Cu more	830
Added 2 lb. Cu more	850
Added 2 lb. Cu more	846
Added 2 lb. Cu more	840
Added 5 lb. Cu more	808

Table I gives a summary of the results of the experiments made in preparing the various rich alloys by the three different methods. Table II gives the chemical analyses of the rich alloys prepared.

DISCUSSION OF THE EXPERIMENTS

These experiments have afforded some interesting data with regard to the temperature rise noted by other observers when solid aluminum is added to liquid copper. While most of the melts were made under such conditions that copper oxide was doubtless present in the liquid copper, some showed that a temperature rise is obtained even when aluminum is added to copper melted under charcoal. Others indicated that the temperature rise observed on adding solid copper to liquid aluminum continues with successive additions. These data prove that part of the temperature rise is due to oxidation of the aluminum and part of it to the heat of formation of the alloys. Practically, therefore, it is advisable to employ oxygen-free copper for making rich alloys, and the copper should either be deoxidized before pouring into the aluminum or be melted under reducing conditions so as to prevent the presence of any considerable amount of cuprous oxide in the copper bath.

Moreover, from a practical standpoint, it is desirable to hold dross losses low in the manufacture of rich alloys as well as keep the melting costs down. By the methods employed in the present experiments, the melting costs were highest for the three alloys when the method of pouring the liquid copper into liquid aluminum was employed. This is to be expected, because two different furnaces were running in this method, one on copper and the other on aluminum. In the other methods, where one solid metal is added to another liquid metal, some saving is had by taking advantage of the residual heat in the crucibles and furnace. The total losses (made up of dross plus shrinkage) and the dross losses were lowest in the case of the method of pouring copper into liquid aluminum. These losses were very heavy in the method where solid copper was added to liquid aluminum.

In considering the dross and shrinkage losses in Table I, it should be borne in mind that the experiments were carried out on a small scale, 25-lb. charges being used. The relative order of the losses in preparing the rich alloys by the different methods is correct, but the actual figures are not representative of large-scale practice. On preparing the alloys on a large scale, the losses would be considerably lower. Moreover, it should be pointed out that ordinarily the dross is not entirely loss in commercial practice, because a considerable recovery of metal would be made by running down the dross and skimmings.

The conclusion arrived at from these experiments is that the most desirable and best way of making any of the rich alloys is to melt the aluminum and copper separately and pour the copper into the aluminum. On a large scale, where, say, 2,000 lb. of the 50:50 alloy is made at a time, a satisfactory procedure is to melt about one-third of the total aluminum in an iron pot or other suitable vessel; after it is melted, cold pigs from part of the remaining aluminum should be thrown in to cool the metal. Here, solid aluminum would be floating around in the liquid metal. The copper should have been previously melted separately, and with the aluminum in the above condition, about one-fourth of the copper should be poured in. The addition of the copper will raise the temperature of the aluminum, but the resultant alloy may be cooled down by throwing in more pigs of cold aluminum. Then about one-fourth or more additional copper should be added and then more cold aluminum, and so on until the two melts have been properly alloyed. The alloy should be thoroughly stirred during the additions to facilitate alloying, and should be stirred well on pouring or ladling out into pigs. These directions are admittedly only very general, and the quantities of the several additions will vary considerably with the temperatures. The manufacture of rich alloys should be carried out under the supervision of a competent melter, and the use of pyrometers for frequent temperature measurements will be of value. In any event, the effort should be made to keep the temperatures as low as is consistent with rapid alloying and not allowing the alloy to freeze in the mixing vessel.

Status of the American Potash Industry

The American potash industry is in a more promising condition than at any time since the armistice. Domestic potash production in 1920 is expected to exceed that of the banner year, 1918. The producers not only have their entire possible output under contract but are being urged to take contracts for next year.

The domestic situation has been bettered by the refusal of the German syndicate to quote prices at American ports. This throws the burden of securing bottoms, negotiating freight rates and the absorption of demurrage on the American purchaser. On the other hand, the producers have had to face labor difficulties and trouble in obtaining materials. In Nebraska, the abnormal rainfall has so diluted the brine as to make much greater amount of evaporation necessary just at the time when fuel prices are at their peak.

Large new plants are being built at Searles Lake, Marysville, Utah, and at New Brunswick, N. J.

Searles Lake producers have reduced the borax content of their potash to 0.5 per cent. In that connection it is pointed out that the borax content of the Searles Lake potash never was so great as to be hurtful when used under normal conditions. The only places where damage resulted, it is stated, were where prolonged drought prevented the washing out of the borax. The lowering of the borax content is a very simple matter and could have been done before had it been known that it possessed an element of danger, producers state. The company which produced the potash which caused some small damage to crops is not selling its potash for fertilizer purposes this year, its entire output having been purchased by chemical users.

ROCHESTER COAL GAS PLANT

The Gas Industry; a Diagnosis and Prescription

The Manufacture of Gas, Although Fundamentally a Chemical Problem, Has Been, and to Some Extent Still Is, Directed on Mechanical Technologic Lines; Healthy Progress in This Industry Requires a Better Knowledge of the Chemical Fundamentals Involved

By R. S. McBRIDE*

THE title of this article implies that the gas industry is ill, and, frankly, it appears so to be. However, this conclusion need not be regarded in a pessimistic spirit, for a recognition of illness is perhaps the best promise of an early cure.

It is no simple disease from which the industry is suffering. A full diagnosis shows both mental and physiological problems. A nervous state of mind which threatens a most distressing case of melancholia is obvious to the casual practitioner who may be called into consultation. However, the root of the trouble is more serious. Careful analysis of all symptoms indicates that the patient is suffering from the gout, which has developed to its most acute and distressing stages despite the fact that the industry is simultaneously suffering from what appears to be an almost incompatible ailment—malnutrition.

A richness of opportunity has led the industry to pass through a period of opulence, during which, without proper self-restraint, it acquired all of the gouty characteristics of the dyspeptic plutocrat. At the same time neglect of important elements that must nourish the industry for any permanent healthy existence gave it the second ailment—malnutrition.

Let us lay aside this analogy and go straight to the root of the matter in plain English. The industry lacks

today a proper vision; it stands of all great chemical industries the most negligent of science and technology except within the very narrow field of mechanical engineering; and it is almost without effective organization in the possibilities for development in lines of future need. It would be desirable to discuss the lack of science alone if this were possible, but the three points of need just cited are so interwoven that it seems impracticable to go into one without discussing all.

THE FUNCTION OF GAS

Except with respect to the ease of storage, gas certainly can be conceded to be the ideal fuel. It is clean and convenient of use and can be most efficiently applied of any heating medium. To a limited extent the industries recognize this, but the public in general, including the vast majority of technologists, has not been educated to an appreciation of this point.

The gas business not only has for its responsibility the supply of such ideal fuel but it has also the duty of furnishing a group of fundamental raw materials for other industrial chemical activities. It takes coal, the lowest form of energy supply, available through almost all parts of this country at the lowest price of any important raw material, and converts it into (1) coke, which is a fundamental metallurgical raw material, an almost ideal substitute for anthracite and an important means for other gas-making and industrial-

*Engineering Representative, McGraw-Hill Co., Washington, D. C.

Washington

heating operations; (2) gas, which is the ideal fuel just mentioned; (3) tar, a liquid fuel of wonderful possibilities in the Diesel engine, a raw material for more organic industrial products than any other of which we know and a source of manifold possibilities in road making, roofing, building-paper manufacture and in other activities; (4) ammonia, which is produced as liquor, anhydrous ammonia or sulphate, as the cheapest inorganic nitrogen resource available on American markets, affording a large portion of the supply needed in explosives, fertilizer and other industries; and (5) light oils, a group of liquids whose possibilities are yet little appreciated for automotive fuel, explosives production, solvents and organic chemical production.

It is a rather appalling task which confronts the industry when the ramifications of its products are thus appreciated. The importance of proper vision and intensive scientific application should at once be apparent.

The gas business, born a century or more ago during that epoch when the rule-of-thumb system of operation prevailed, has collectively been ancestor worshipping in the most impressive Oriental style. However, since industries have ceased to pass from father to son like real and personal property, we have come into the new era of industrial life, and those industrial activities which have been born in the latter period are independent in thought, vigorous in personality and wholly unwilling to give even that respect to father and mother which enjoys Biblical admonition. Witness the automobile, the telephone, the airplane and similar recent developments. Certainly no tradition has hindered here. Gas, however, has been the antithesis of these.

The reason for this limitation of the gas business has apparently been the character of the men consistently chosen to direct the thought of the industry. The coking of coal, the gasification of oil and the production and handling of byproducts is fundamentally a chemical problem. Unfortunately, however, it has been almost exclusively directed by the mechanical engineer without the co-operation of chemical experts. The industry has, therefore, become almost a pseudomorph of mechanical engineering. The crystal habit of mechanical technology has prevailed almost to the exclusion of chemical thought. The machinery of the industry has been excellent, but the processes and the products have not developed correspondingly. The situation now demands an opportunity for free development of the natural habit of this chemical business. We would then see those crystal forms which are the natural product of chemical and physical science quickly taking shape, and a more perfect result would inevitably follow.

PUBLIC UTILITY OR MANUFACTURING BUSINESS

Not all of the criticism offered of the present state of affairs in the gas business would be fair or reasonable if it were not clearly recognized in its presentation that some of these conditions are the inevitable result of operation of the business as a public utility. Gas manufacture has been restricted by regulations more stringent than control in any other chemical activity. Investment has been safeguarded by artificial means, but no opportunity has been given for the encouragement of epoch-making advancement in the business. Limited returns upon investment have made inevitable a certain measure of conservatism which never would have followed had it been an unrestricted manufacturing industry. Despite these obstacles, however, cer-

tain important developments can and should be achieved. Operating as a public utility rather than as an essentially manufacturing concern, the gas works manager has usually had to think of reduced cost per thousand feet of gas rather than of his major technical problems. R. B. Brown, of Milwaukee, in commenting on this particular point, brings out strikingly one of the most important reasons why the science of gas manufacture has been thus neglected.

The possible savings in the cost of gas manufacture may usually be enumerated in fractions of cents per thousand. The possible savings in the fixed charges on investment through more intensive sales policies and the increase in the units of gas sold per capita and per dollar of investment have been so tremendously greater that the most progressive and most successful operators have been those that have devoted a great deal of their attention toward increasing the volume of sales. It is a far cry from the first days when 3,000 ft. per capita was considered a good year's business and when 150 to 170 maximum days was a reasonable load factor, to present-day conditions where 10,000 ft. per capita is only a stepping stone to greater things, and 280 to 300 maximum days is considered a fair load factor.

The corresponding reductions in the cost of capital charges—interest and depreciation and taxes—per unit of gas sold have been tremendous and we are not through with that phase of the situation yet, though of course the present low purchasing power of the dollar and the present high costs of interest and of taxes have blinded many people to the fact that the greatest possible reduction in cost of operation still remain on that side of the job. Personally I am not at all blind to the possibilities in improvement of gas production processes, but financially these are not so attractive today as are many possibilities in other phases of the operation.

A whole article might be written on the subject of whether the gas-producing part of the city gas business should not be removed from the public utility field and be given free rein as a manufacturing business. However, that for the present would be altogether too great a diversion from our major theme.

VARIETY IN PROCESSES IMPORTANT

Each type of bituminous coal has its own important characteristics with respect to coking. This fact is well known and is admitted by the gas man when he is pressed for comment on this particular point. However, the significance of the point has been concealed by the gas and coking interests in saying that certain coals are good coking coals, others are poor coking coals and some are non-coking coals. As a result, in the war period, when the promoters of a certain coking process came to Washington and set forth the claim that their process could "coke any coal" they stirred official Washington tremendously. In fact they created so great a stir, despite the fact their process had no fundamental novelty to offer, that the President himself was led to take personal cognizance and order an investigation of the processes described.

The recognition of limitations of coking of each type of fuel is not enough. We should take the other point of view and study and emphasize the advantages or possibilities of each particular supply. A high-nitrogen coal is to be avoided on the score that the nitrogen content of the gas is likely to be high and, therefore, the gas is lean and may not meet certain standards of quality which have been fixed. However, if we stop to consider the possibilities of such fuel for the greater production of ammonia when rightly coked we see that this characteristic may become a blessing and not a curse of the fuel. Similarly, if we are seeking solely a

MINERAL FUELS PRODUCTION IN U. S.

This diagram, prepared by E. G. Stevers of the U. S. Geological Survey, shows the values of mineral fuels produced in this country from 1906 to 1918, inclusive. The insert rectangles show the relative total value of these fuels for the 13-yr. period.

hard, dense coke and wish a high coke yield we would not choose a typical high-volatile Pittsburgh coal to use alone. On the other hand, when we consider the possibilities of this high-volatile fuel in the greater production of gas, the much higher yield of light oils and tar, the increased possibilities in other directions thus may far outweigh the limitations and characteristics of the coke. In other words, we emphasize the possibilities and not the handicaps of our raw material.

Today practically all the gas made in this country from solid fuel is produced in the "D" retort, the Low-type water-gas machine, or the chamber coke oven of

Koppers or Solvay type. Why we are so limited in processes is an economic question of importance. There is no doubt that these particular processes have fundamental advantages of great importance. If it were not so they could not possibly have endured so long and have been applied so extensively. However, the future must give us better opportunity than this. Low-temperature carbonization in metal retorts, the use of vacuum retorts, continuous operation, vertical retorts, steaming of coke in retorts, fractional condensation of liquid products of distillation and numerous other such possibilities are receiving some of the attention which they deserve. Out of all these we will doubtless develop a much greater variety of processes permitting the application of many fuels not now well suited to gas manufacture, because the thermal history to which these processes limit us is not suited to the characteristic of the coal.

KNOWLEDGE OF FUNDAMENTALS REQUIRED

The thermal history of the gas is important. The gas man says that the richest gas comes out of the coal first and that the lean gas remains in the coke until the end of the period of coking. This is another case of misleading use of terms which has probably been responsible for much of the misdirected effort in the coking of coals. In destructive distillation, as in any simple distillation process at lower boiling points, lighter fractions come off first and the heavier fractions remain behind until the later stages of the process. However, in destructive distillation of solid materials the quantity of the lighter materials which comes off in the early stages is so great that these materials flow rapidly out of the heated zone and many of the primary products of gasification leave the retort without being subjected to thermal disintegration. As the coking progresses the temperature increases, the quantity of material driven off per unit of time decreases and, therefore, the time and temperature of exposure of the initial products of the distillation are greater. We thus have at the later stages of heating the products of secondary decomposition of the primary products of distillation.

No one knows exactly what is the thermal history of the gases in most of the coking processes. We have still less idea as to what are the temperature ranges of formation and decomposition of each of the gas and vapor

BLUE WATER-GAS PLANT

This is a diagrammatic presentation of a blue water-gas plant designed to supplement a natural gas supply. The Bartlett-Hayward Co. was the designer and builder of this equipment. Capacity, 12,000,000 cu.ft. per day.

constituents. We know virtually nothing of the shielding effect of one gas upon another and are similarly ignorant as to the influence of time and solid surface action upon these thermal chemical reactions.

Take the case of ammonia alone. We have perhaps the greatest fund of physicochemical information regarding this constituent of crude gas that we have for any of the important products produced by coal distillation. However, except for limited conditions, we know very little as to the influence of factors upon the yield of ammonia. We know vaguely that the presence of a certain amount of water vapor is important in order to protect the ammonia or to facilitate its formation. (No one knows just which it is.) However, we are not quite sure to what extent the higher moisture content of the coal charged is justified, because this would require rather accurate information to balance against the increased ammonia yield the simultaneous increase of fuel requirement for heating the retort or the oven.

The products of low-temperature distillation give great promise. But who knows what low-temperature tar oils are worth? No one apparently. As an important element in our future liquid fuel supply we cannot afford to ignore these liquid products of coal distillation. If we can achieve anything like the estimated yields of these products, say 40 or 50 gal. of liquid per ton of coal treated, the carbonization of large quantities of coal may be justified in order to secure these liquid fuel resources alone. However, until we know much more of the fundamental characteristics of the liquid constituents of crude gas as coming from coal we can neither have direct manufacturing processes for their production nor appreciate the utilization possibilities.

In the future it appears likely that the chemist will come to the mechanical engineer and say somewhat as follows: "Here is the coal we intend to use. We wish to subject it to a certain thermal treatment. We will specify for you the condition of the coal and quantities of the various products which must be handled. We will give you the limitations of temperature, both maximum and minimum, at each stage of the handling of the raw coal, the crude gas and the various products eliminated from the gas. Mr. Mechanical Engineer, you will design and build us a machine to carry through the process within these limitations." Then, and not until then, can the mechanical engineer intelligently and effectively design gas-making equipment.

Of course when that time comes doubtless the engineers and the financial interests will insist upon some measure of uniformity in the processes which the chemist will ask for. This will be only proper, for it will

be no more reasonable to build a plant for a single coal than to build a house to suit all the peculiar ideas of one individual. If we build our gas plant for a single coal we place too severe a limitation of raw material which it must have. Nevertheless, recognizing this necessity for certain process uniformity, we will find a much greater variety in thermal history possible for the treatment of our fuels.

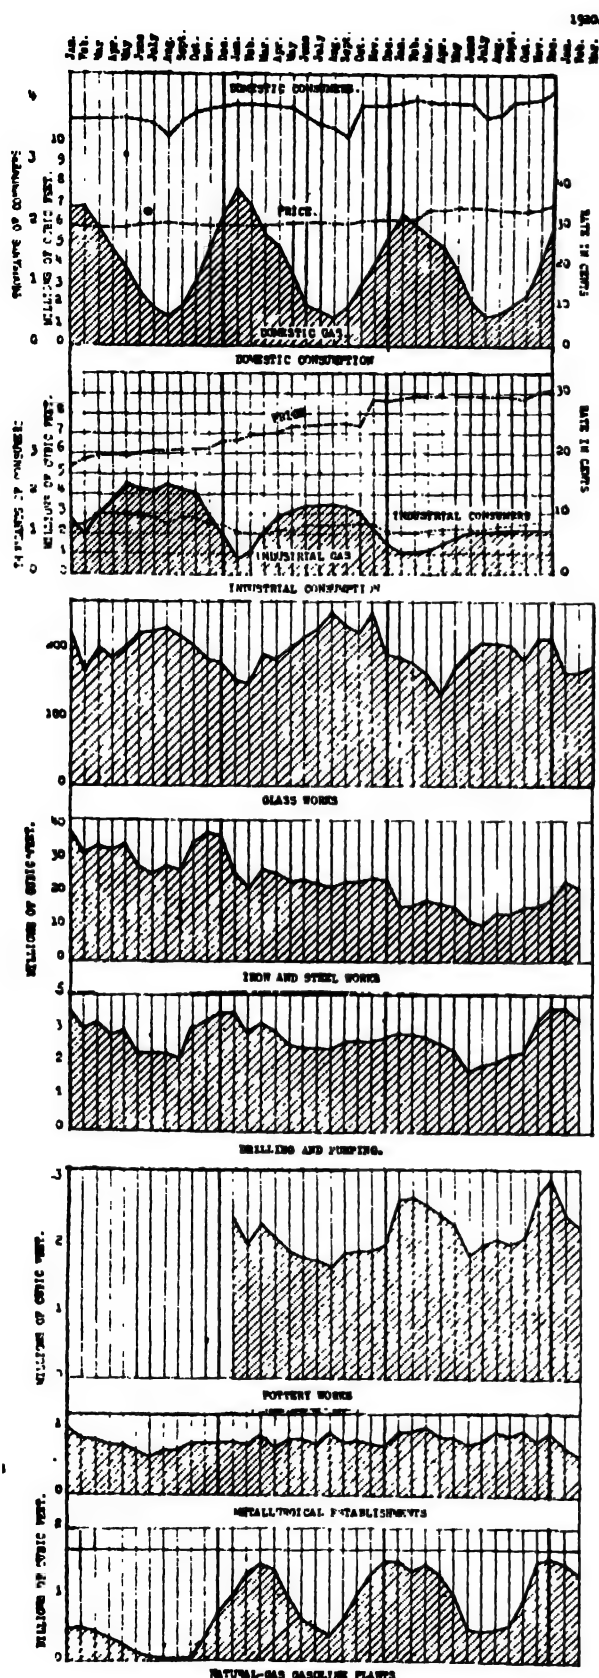

A MODERN VERTICAL RETORT PLANT

This installation shows diagrammatically a typical bench of six or nine retorts with waste-heat boiler, fuel handling, ash handling and producer gas heating accessories as built by the U.G.I. Contracting Co. It is one of several modern types, using intermittent vertical retorts.

The technology of electric power transfer over distances of 200, 300 and more miles is producing a great stir these days. We are talking about superpower systems, with the dispatching of current from one generating system to another system normally supplied by others, thus achieving wonderful advances in generating efficiency and power supply. At the same time natural gas transmission technology has been advancing. Today we have interconnected natural gas-transmission lines covering parts of eight states. Gas actually moves regularly from West Virginia to supply the city of Cleveland, and yet little attention has been given to these achievements. They are equally worth talking about.

Today there exists in western Pennsylvania, West Virginia and adjoining territory a supply of billions of tons of coal. It is a problem how to move the energy which this coal affords us to the seaboard, and into large industrial centers. There are three means to be used. We may move the solid fuel itself; this, of course, will be for many years to come the backbone of the transmission of energy from natural resource to the appliance of the user. However, we must take into account the possibility of generating gas by coking the coal, by gasification of the coke or by other yet undiscovered processes and the transfer of this gas to the industrial and municipal centers. The technology of

FLUCTUATING GAS DEMANDS BY MONTHS AND INDUSTRIES

Figures for domestic consumption, industrial consumption, glass works, iron and steel works, drilling and pumping, pottery works, metallurgical establishments and natural-gas gasoline plants. The monthly fluctuation in gas demand of various industries here shown is one of the serious difficulties encountered by the gas business. With such fluctuating demands, costs are, of course, correspondingly high. These data were prepared by E. G. Stevers of the U. S. Geological Survey.

this business is still young, but it is a thrifty, sturdy youngster.

We can move the coal as above mentioned, but in doing this one pound out of each four is consumed on the way for locomotive fuel simply to haul the remaining three. Judged on the basis of thermal efficiency, this, together with the low yield of heat in the ordinary coal-burning equipment, does not give us any very encouraging result to consider. Suppose instead of this we convert the maximum feasible amount of our fuel into gas and transfer the gas, say, 150 miles. This transfer, according to present none too good natural gas technology, requires only about 5 per cent of the energy for the movement of the remaining 95 per cent such distances as 100 to 150 miles. With careful study of the transmission problems, taking advantage of the latest developments in our knowledge of the physics of the flow of gas and of compression and with the mechanical engineering achievements surely to be expected in the coming decade, it is not too much to expect that the problem of energy transfer from resource to municipal supply will be accomplished by means of gas with an efficiency as great as if not greater than by any other medium. We have similar problems in the electrical business, where the finest of engineering talent is studying just how the balancing of loads, adjustment of load factor and power factor, and power line design will give us the greatest energy efficiency possible. The gas man may well take heed of this sort of investigation and development. With the fundamental advantage that gas can be generated with much higher thermal efficiencies than electric current can be generated by the use of any known processes of today, the gas engineer has much to encourage him.

Of course it would be foolhardy to assume that gas is destined to displace electricity. There is no need for such thought. The proper attitude is that gas and electricity are naturally supplementary, the one of the other. You might even call them "the gold-dust twins" of municipal energy and fuel supply. We need municipal fuel surveys in every large community or district. The total heating and power demands should be analyzed and the most effective means determined for meeting these needs. Gas, electricity and solid fuel will all have their share, of course, and it is important that they should work together to this end. For example, it is recognized as foolish in the present day for the gas industry to waste much time in the house- or industrial-lighting field. First of all, in this business we must have convenience, and there is no immediate prospect that gas can afford anything like the convenience of electricity in this particular work. Why, therefore, waste effort in trying to substitute gas for a more effective, more directly applicable medium? It is admitted to be far better to expend the effort which might thus be wasted on gas in persuading the householder or industrial plant manager to spend the money for any gas-burning equipment in lines where gas is an ideal fuel. For example, the cost of piping a house for gas light can much better be directed to the purchase of gas water-heating equipment or other modern effective devices that can be defended against all comers on the score of both efficiency and convenience.

GAS UTILIZATION AN IMPORTANT STEP

It is estimated that not more than 35 per cent of the natural gas delivered in the household is used effectively. In other words, nearly three times as much

service could be obtained from existing gaseous fuel supply in natural-gas territory were proper modern utilization methods pursued. From recent work done in several disinterested laboratories, it appears that this estimate and conclusion is amply justified. The reason for this rather appalling situation is not far to seek.

Until quite recently there has been no effort made in the scientific design of natural gas-burning equipment. A typical industrial-gas burner was a piece of pipe with a pipe cap on one end, a few holes drilled irregularly along its length and a smaller pipe projecting through the other end to supply the gas, perhaps with some means for controlling the air which entered between the smaller and larger pipes, very often no means at all being used for air control. Such device is a gas burner; it is more than this. It is a wonderful gas waster. Manufactured gas appliance manufacturers have not built quite as blindly as this, but some have almost done so. However, all are beginning to recognize that an appliance really does not burn gas. It burns a gas-air mixture. This at once impresses them with the fact that the appliance is a machine to make a mixture which it then subsequently delivers at the point where it is to be burned.

When appliance design reached this stage of interest in the production of air-gas mixtures, it was found that there was no information whatsoever as to the principles of air-mixer design. A few appliance makers have apparently studied the problem a little and have varied their appliance enough to give great improvement, but only recently have the fundamentals been considered. Within the past two years the first comprehensive, thorough work on this problem has been undertaken.

This work took up burner design in three parts. First, how to introduce the gas into the burner, maintaining in the gas stream the maximum of the kinetic energy possible; second, how to use this kinetic energy in building up a mixture, and third, under what conditions this mixture should be delivered to be most effectively burned and the energy of the flame utilized.

This work is only a beginning, however. It illustrates the necessity for study of viscosity, stream-line flow and momentum relations in burner design. The throat design must take into account both theoretical factors and practical matters of convenience in operation, ability of the operator to keep the appliance clean, etc. Already as a result of this work the appliance manufacturer can produce and handle almost "ideal" air-gas mixtures with low pressure gas. Formerly these possibilities were considered impossible without the use of air or gas under high pressure. By means such as this it will be possible to double or treble the efficiency of gas burning under many conditions, and as a result gas will be made available in many fields where before its relative higher cost per heat unit made it unavailable. Then, too, by simply better burner design, moving the burner closer to the kettle and teaching the householder a few simple principles, we shall find that manufactured gas at its much higher cost can replace natural gas, as these supplies decrease and finally disappear, without any increase in cost per month for service rendered above the expense to the householder for natural gas used as now so carelessly and inefficiently.

GAS AN INDUSTRIAL FUEL

Problems of industrial gas application are not limited alone to matters of appliance design. Here we have

much the same situation as was described in the coking of coal. We need first to study the fundamentals of the industrial process. We must find out the thermal history to which we wish to subject our materials and then it will be possible quite easily to apply the gas for the production of the temperature-time relations which are desired. Metal melting, metal heat treatment, enameling, baking, boiling or heating the tea kettle all have their problems to be solved. When it is known just how these operations should proceed for perfect satisfaction, the means for accomplishment will quickly follow both in appliance design and in effective gas merchandising. Not only shall we find increased thermal efficiency resulting but it is not too much to expect that actual decreases in fuel cost will come despite the continued rise in the price of fuel raw material, and not only will these fuel advantages occur but there will also be built up opportunities for better quality of product, more uniform plant operation, more satisfactory conditions for work of the furnace and appliance operators, cleanliness of surroundings and numerous other advantages that always follow replacement of solid fuel by gas.

PRESENT LIMITATIONS

It would be foolish to close a discussion like this without pointing out one limitation which is just as serious as that of our present limitation of scientific knowledge. In this the matter of construction cost and the high cost of money are referred to. At the present time, even if we wished, it would be foolish to undertake to replace solid fuel by gas for extensive house heating or for other operations where the seasonal load curve is bad. Today it costs \$2, \$2.50 or \$3 to build a plant where previously \$1 sufficed. The public utilities that used to get money for such construction at 5 or 6 per cent because of the stable nature of their business now are fortunate if they can secure the money for 7 or 8 per cent. As a result, we have today capital charges, interest, amortization, taxes, all on a basis of about three times as much per unit of gas output. This, of course, places severe limitation upon the expansion of the gas manufacturing industry today, for it makes the capital charge element of gas cost almost as much as the total delivered price was formerly; and the operating expenses, too, are higher today than ever before.

On the other hand, solid and liquid fuel costs have advanced similarly. It is an old story to discuss our "thirty-cent" or "forty-cent" dollar in any market. It is not to be expected, therefore, that this financial limitation will permanently prevent improvement of the opportunity in the gas business. It is high time, therefore, to undertake all of that essential investigation¹ in development work on fundamentals which will permit construction along right lines as soon as construction of any sort begins.

It should be recognized, too, that today the gas plants of the country are called upon to supply all or more than they can produce at seasons of maximum demand. Construction for the future, therefore, will be largely to supplement present capacities. We should not expect it for some years to come to be primarily a replacement of existing processes.

It is none too soon, however, to think of the new developments as being those which will be the backbone of the industry a decade or two from now. The great importance of their proper direction is thus at once evident.

Extraction of Calcium Oxide From Calcined Magnesite

L. H. DUSCHAK, chemical engineer, Bureau of Mines, has recently made a laboratory study of the extraction of the free CaO with water free from CO₂ from calcined magnesite. From the solubilities of Ca(OH)₂ and Mg(OH)₂, Seidell, "Solubility of Inorganic and Organic Compounds" (2nd Edition, 1919), it is estimated that at ordinary temperatures calcium hydroxide is fifteen to twenty times as soluble as magnesium hydroxide. It should, therefore, be possible to obtain a separation good enough for the purpose indicated by extraction with water.

SOLUBILITY OF Ca(OH)₂

Temp., Deg. C.	Grams per 100 g. H ₂ O Ca(OH) ₂	CaO
0	0.185	0.140
20	0.176	0.132
30	0.159	0.120
50	0.128	0.097
100	0.077	0.058

SOLUBILITY OF Mg(OH)₂ IN GRAMS PER LITER AT 18 DEG. C. BY CONDUCTIVITY METHOD

Solubility	Authority	Date
0.009	Kohlrausch & Rose	1893
0.008	Dupre & Brutus	1905
0.012	Tamm	1910

As some preliminary experiments indicated that the availability of the lime varied with the temperature of calcination, the majority of the extraction tests were made on material obtained by calcining portions of magnesite in a porcelain crucible at a fixed temperature for a definite time. The procedure commonly used for extracting the lime was to transfer the calcined material to a 200 c.c. graduated flask and add distilled water which had been freshly boiled to free it from CO₂. The flask was allowed to stand with occasional agitation for a fixed time, usually over night. The liquid was filtered if necessary, and a suitable volume, usually 100 c.c., was titrated with standard hydrochloric acid using phenolphthalein as indicator.

With the exception of a few experiments which will be noted below, the results in the accompanying table were obtained by the method just outlined.

A portion of the solution from test 14 was analyzed gravimetrically for CaO and gave a result corresponding to 4.5 per cent CaO. This shows that the alkalinity found by titration is due almost entirely to the Ca(OH)₂ in solution. This was confirmed by an experiment in which 3 g. of pure MgCO₃ and 0.150 g. CaCO₃ were mixed and calcined for one hour at 950 deg. C. The product was then leached with 300 c.c. water. Gravimetric analysis and titration on a 100-c.c. portion of this solution yielded the following results:

	Grams		Grams
MgO by grav	0.0008	CaO by grav	0.0280
CaO by titr	0.0307	CaO by calc	0.0280

In test 3 the calcined material was agitated with water for 3 hr. with CO₂ free air, and in test 15 there was similar agitation for 2 hr. It is evident that agitation in this way for 2 or 3 hr. is the equivalent of considerably longer leaching without agitation.

It will be noted that with the dead-burned magnesite and the magnesite bricks only a small portion of the CaO was found to be available, due, no doubt, to the high temperature of calcination. This influence on the tem-

perature of calcination is also indicated in some of the tests at 1,000 and 1,050 deg. C. In order to determine whether the effect of calcination at high temperature was simply to decrease the rate of solution of the lime, a duplicate of test 13 was run, in which the calcined material was rolled with water for 5 hr. in a glass bottle containing glass marbles. The result was 1.76 per cent CaO, only 0.02 per cent greater than with the ordinary method of leaching. Grinding in this way was tried with several other samples, including some of the dead-burned material, without increasing the amount of soluble lime. This would indicate that calcination at high temperature causes the CaO to enter into some compound which is not decomposable by water.

Research and the Production of Leather Belting

Tribute is paid to the service the chemist has performed in the manufacture of leather belting, in a recent issue of the *G. W. W. Bulletin*, the house organ published by Gaston, Williams & Wigmore, Inc. Speaking of the Graton & Knight Manufacturing Co., of Worcester, Mass., the *Bulletin* says:

"A large and completely equipped chemical laboratory was established by this company a number of years ago and has consistently availed itself of every scientific discovery tending to increase quality. A staff of chemists under a chemical authority on tanning is constantly at work. All raw material is tested and in addition much work of an experimental nature is done in tannage, currying and other processes."

The Post-War Status of the Ceramic Industries*

An Outline of the Need for Reducing the Fuel Consumption and for the Introduction of Labor-Saving Devices, With a Short Review of the Economic Status in the Manufacture of the Various Clay Products

By A. V. BLEININGER

THE general perplexed condition of American industry extends of course to the silicate industries, dealing with the manufacture of the various clay products, glass and enamel metal ware. The railroad situation, the lack and high cost of fuel and the acute labor conditions are responsible for the most difficult situation which has ever confronted these industries. The two primary aims of the manufacturers must of necessity be to reduce the fuel consumption and to strive for the introduction of labor-saving devices. The first part of this program is being attacked through the use of the continuous and especially the tunnel-car kiln. Rapid progress is being made along these lines and a considerable number of such kilns are being built. The adaption of the tunnel kiln to the manufacture of heavy structural products in large tonnages has not yet been completed and the problems of the successful water-smoking and oxidation of such products still awaits complete solution.

The introduction of the tunnel kiln is undoubtedly one of the most important advances ever made by the industry and means not only a saving in fuel of not less than 50 per cent but a reduction in the labor cost as well. It is interesting to note that the metallurgical and allied industries are awakening to the advantages of this type of furnace and are adopting it for calcining and annealing operations.

There are two types of tunnel kilns to be considered—one in which the gases come in direct contact with the charge and the other in which the heat is transmitted through the walls of combustion chambers. The former type requires the use of saggers for the burning of glazed ware, but in the latter the articles may be set unprotected. These kilns have also been built of the twin type consisting of two adjoining tunnels through which the cars pass in opposite directions. Progress is being made with reference to the use of producer furnaces attached to the kilns and the employment of mechanical stokers. A considerable number of tunnel kilns are now in operation and maintain temperatures as high as 1,450 deg. C.

Labor-saving devices, especially with reference to the more economic handling of raw materials, mechanical driers, automatic molding machines, etc., are being introduced rapidly in the different industries.

BUILDING AND PAVING BRICK

The high cost and scarcity of labor, the difficult freight situation and the extraordinary increase in the price of coal have had a strong depressive influence especially on the plants compelled to ship their product. The prices of the product have gone up to unprecedented levels through the enormous increase in the cost

of manufacture. The difficulty of securing labor has been a very important factor, since the hard manual labor of the brick yards does not attract the best workmen. Altogether the building and paving brick industries are laboring under serious difficulties. This applies still more strongly to the paving brick industry, dependent as it is upon road improvements and new projects for which municipalities find it difficult to obtain the money. The demand for brick products is fundamentally strong and is bound to be great for at least the next five or ten years.

BUILDING TILE AND SEWER PIPE

The demand for hollow building tile is increasing very rapidly with the enlarged use of stucco construction and the plants have ample orders. They, like the other structural clay products industries, are seriously handicapped by the prevailing conditions.

The sewer pipe industry, like the manufacture of paving brick, is hampered by the difficulties in the way of carrying out municipal improvements.

TERRA COTTA

This industry after its dormant existence during the war has revived considerably and is certain to regain its pre-war status as soon as the conditions permit it. The manufacturers are making rapid progress in the development of superior bodies and techniques. In one establishment the tunnel car kiln is being used, a step which is being watched with considerable interest.

In the Middle West States the question as to the feasibility of washing the terra cotta clays is being discussed and may lead to the erection of central preparing plants.

FLOOR AND WALL TILES—POTTERY

Manufacturers of floor and wall tiles have been considerably hampered by the general obstructions to industrial activity and the labor situation, so that it has been difficult to maintain even approximately normal conditions.

The pottery industries have suffered particularly with reference to their supply of raw materials, especially feldspar. This condition has become very serious, and for this reason increasingly large quantities of soda feldspar are being introduced in the body. In addition to these difficulties the question of the fuel supply has become very critical, especially in the districts where natural gas is no longer available. Unheard-of prices are being paid for coal in the eastern pottery districts.

A report issued some time ago jointly by the U. S. Potters' Association and the Bureau of Standards brings out the fact that the domestic kaolins are suitable for the manufacture of white ware pottery, but that at the present time the supply of primary kaolin is not sufficient

*Published by permission of the Director, Bureau of Standards.

to meet the needs of the industry. The use of imported English china clay therefore cannot be dispensed with until additional sources are developed in this country.

The demand for high-grade domestic porcelain tableware is constantly increasing and is being met by the enlargement of a number of potteries and the erection of new plants.

The tunnel kiln is rapidly establishing itself as a permanent feature of potteries, a situation very much to be desired.

ELECTRICAL PORCELAIN

The newer developments tend toward the more extensive introduction of the casting process in the making of high tension porcelain and the employment of somewhat higher burning temperatures.

More critical tests are being employed in the examination of the porcelain structure, such as by the penetration of alcoholic eosine solution under pressure, and the quality of the material is being raised generally. Extensive researches are being conducted by a number of concerns which strive for improvement in the product.

In the manufacture of spark plugs the quality has been pushed to a high degree of perfection and there is no doubt that these motor accessories are decidedly superior to the European product. High temperatures, about 1,450 deg. C., are employed in the firing, and tunnel kilns have been successfully adapted to this purpose.

CHEMICAL STONE WARE

This industry has been established on a firm basis and has made the United States independent of European products. Both as to quality of the material and the technique of producing intricate shapes the standards are very high.

THE GLASS INDUSTRIES

The demand for glass products of all kinds is very great and is not being adequately supplied, due to conditions beyond the control of the industry. The deficiency in fuel supply has been a serious drawback to production. The elimination of natural gas has made it necessary to equip many plants with exceedingly large and expensive producer gas plants and to adapt the tank practice to this fuel.

The activity in developing new mechanical processes has been particularly marked, especially in the manufacture of window glass and hollow ware. The methods of drawing straight sheets from the molten glass, the automatic feeders and presses, and tube drawing machines have all contributed toward lowering the excessive labor cost connected with the old practices. Incidentally it might be said that the wages of the glass operatives have gone up to high figures, so that it is not unusual to find gathering boys receiving earnings at the rate of \$2,000 per year. Improvements have also been made in the preheating of the pots and the installation of the tunnel kiln for this purpose.

ENAMELED METALS

The manufacture of enameled cast-iron and steel products has been handicapped by difficulties in securing raw materials, especially feldspar and cryolite. Enameling processes are being applied to an ever-increasing number of articles, and as a result the industry is expanding rapidly. From the research point the results of the work done by the Bureau of Standards on

the subject of "fish scaling," a common defect, are of importance and it can be safely predicted that this source of loss can soon be eliminated.

REFRACTORIES

As compared with war-time activities the demand for these products is small in volume, though the plants are continuing operations as regularly as is possible under the prevailing conditions. The demand for special refractories of high quality is very good and there are strong indications that considerations of quality will in the future govern sales to a much greater extent than they did in the past. It is being realized more and more that the first cost of refractory materials is secondary to quality. The work of such organizations as the American Society for Testing Materials in advocating specifications for refractories is bringing returns and users are coming to realize the importance of having definite requirements.

Basic refractories are still being made from American magnesite and the prospects are fair that the Washington deposits will remain a permanent source.

Work in connection with the further development of improved materials for electric furnaces is in progress. The use of silicon carbide as a refractory has made rapid strides.

In the manufacture of graphite crucibles it has been shown by the Bureau of Mines that American clays of the ball clay type are as well suited for the purpose as those formerly imported from Germany and in some respects are superior.

The refractories used in the glass industry are still being made to a large extent from domestic raw materials, though some shipments of Gross Almerode clay have been received. Considerable progress has been made in connection with the improvement of tank block compositions and firing treatments which should yield longer tank life.

RESEARCH WORK

It is gratifying to note the realization on the part of the manufacturers that industrial research has a real money value and the demand on the part of the industries for young men trained in ceramic engineering has been greater than the supply. Many concerns have established works laboratories when formerly they could not be interested in activities of this kind. In several instances associations of manufacturers have established either a joint laboratory or are supporting research fellowships.

ASSOCIATIONS

A very important factor in developing the new spirit of co-operation has been the associations of manufacturers, such as the National Terra Cotta Society, the National Paving Brick Association, the Hollow Tile Association, the Common Brick Manufacturers' Association, the U. S. Potters' Association and others.

From the standpoint of technical development the American Ceramic Society has undoubtedly been the most important factor. The creation of divisions representing the several branches of industry has been a notable step in bringing about closer co-operation between the manufacturer and the technical man and the scheme is already yielding good returns. The society has been fortunate in the wide vision of its officers, who have seen the opportunities for greater service and have grasped them.

Products From Dry Distillation of Matita Asphaltum*

By C. NICOLESCU-OTIN

BITUMEN is a very complex substance, and to be able to examine the properties of its constituent parts, it must be subjected to a distillation process. Materials are thereby obtained which do not exist as such in the original, but are split off during the course of the destructive distillation and which permit us to see the nature of the complexity of the bitumen.

The distillation took place in retorts, made of earthenware and iron, and the temperature was measured with a Le Chatelier pyrometer. Various gaseous, liquid and solid products were obtained. At the beginning of the distillation, the evolution of much water vapor was remarked, which comes from the water that is mechanically combined. Then, when the temperature increased to 400 to 460 deg. C., large quantities of a bluish-gray gas were produced. This gas contained considerable H_2S .

As the temperature increased, the gas gradually lost its color, and around 730 deg. C. its content in H_2S and water vapor had changed, due to the molecular decomposition that had taken place.

The gas contains about 1,500 l. of H_2S in 180 cu.m.—the quantity obtained from one ton of the bitumen—and possesses the following composition: 12.1 per cent CO_2 , 2.6 per cent C_nH_m , 1.9 per cent O, 13.1 per cent CO, 29.8 per cent H, 34.7 per cent CH_4 , and 5.4 per cent N.

The asphaltum contains 0.88 per cent N, of which 24 per cent is recovered in the ammoniacal liquors as NH_3 . This means that for every ton of bitumen there is obtained 2.5 kg. of NH_3 or 10 kg. of sulphate of ammonia. This quantity is almost equal to the yield procured from coal.

The solid residue, left in the retort after distillation, consists of the mineral part of the asphaltum, mixed with 5.6 per cent very fine carbon. The most valuable product of the distillation is the tar, which represents about 46.6 per cent of the weight of the bitumen. The tar is olive colored and holds in suspension very finely divided carbon. It has been noticed that the iron of the retort facilitates the decomposition of the tarry vapors, producing thereby a lesser quantity of tar—47 per cent—with more carbon in suspension—1.7 per cent—in comparison with the yield obtained in an earthenware retort, 56 per cent tar and 0.6 per cent carbon in suspension. The tar has a specific gravity below unity, varying between 0.908 and 0.930 at 18 deg. C., indicating that it must contain a large quantity of hydrocarbon oils and paraffines.

FRACTIONAL DISTILLATION OF THE TAR

The fractional distillation of the tar, first up to 310 deg. C. under normal pressure and then between 200-275 and 275-310 deg. C. under a vacuum, yielded fractions, with the corresponding specific gravities, are given in Table I.

Furthermore, these fractions were analyzed to find their ultimate composition and the iodine, saponification and total acidity numbers were determined. The results are given in Table II.

*Abstracted and translated from *Bulletin de la Section Scientifique de l'Académie Roumaine*, vol. 5, pp. 129-38.

TABLE I

Fraction	Per Cent of Tar	Specific Gravity
Up to 170°C.	6.23	0.7900 at 20°C.
170-230°C.	9.73	0.8420 at 20°C.
230-270°C.	9.45	0.8770 at 20°C.
270-310°C.	10.70	0.8990 at 20°C.
200-275°C.	15.90	0.9425 at 25°C.
275-310°C.	5.55	0.9725 at 25°C.
Above 310°C.	23.96	1.0060 at 15°C.

TABLE II

Fraction	%C	%H	%N	%S	%O	Iodine	Sapon.	Total Acidity
Up to 170°C.	83.73	12.66	0.41	0.11	3.09	150.85	12.31	2.74
170-230°C.	84.94	11.51	2.52	0.06	1.42	101.06	14.65	4.71
230-270°C.	85.78	11.86	0.87	0.09	1.90	62.47	20.12	10.12
270-310°C.	84.27	10.96	1.24	0.09	3.44	51.29	12.34	0.68
200-275°C.	81.67	11.57	2.42	0.38	3.96	34.54		
275-310°C.	85.18	10.89	1.22	0.42	2.29	31.63		

The oxygen was determined by difference.

These results indicated that the elements entering into the composition of the bitumen, namely, C, H, S, N and O, are found in all the fractions; that the saponification and acid numbers are relatively small, but that the iodine numbers are large, indicating a considerable proportion of non-saturated cyclic and aliphatic hydrocarbons; that the quantity of these compounds present diminishes as the ebullition point increases.

To determine the quantity of non-saturated cyclic hydrocarbons in relation to the non-saturated aliphatic hydrocarbons contained in the fractions, the Nastjukoff reaction was used, whereby the formolite number was found by means of formaldehyde. The formolites themselves were also analyzed and the combined results are given in Table III. As in Table II the O percentages are found by difference:

TABLE III

Fractions	Formolite Number	Composition of the Formolites, per Cent	C	H	N	S	O
Up to 170°C.	42.55	71.50	10.01	2.90	1.58		14.01
170-230°C.	36.25	73.37	11.64	4.11	1.57		9.31
230-270°C.	48.50	74.25	10.35	5.38	0.97		9.05
270-310°C.	72.16	77.15	11.58	4.67	0.96		5.64
200-275°C.	35.33	73.88	10.67	3.50	1.30		10.65
275-310°C.	38.90	78.25	10.35	4.15	1.03		6.22

From the above, it is seen that the formolite numbers are relatively small and that the formolites contain the five elements C, H, S, N and O, which are found in the sulphonated derivatives of the original products, which substances contained S and N and probably O as well in their molecules.

In order to substantiate our conclusion that the formolite reaction eliminates all the compounds containing N, S and O from the fractions, the liquid residues were analyzed and were found to contain C and H only. The results are given in Table IV.

TABLE IV

Fraction up to	170°C.	170-230°C.	230-270°C.	270-310°C.	200-275°C.	275-310°C.
Per cent C	86.90	87.27	87.12	87.35	86.62	86.12
Per cent H	12.82	12.62	12.76	12.49	12.92	13.46

The exact ratios between the cyclic and non-cyclic unsaturated hydrocarbons present in the original fraction can be determined by means of the iodine numbers of these very residues, by taking the difference between these numbers and the iodine numbers of the fractions. They are given in Table V.

TABLE V

Fraction	Up to 170°C.	170-230°	230-270°	270-310°	200-275°	275-310°
Iodine number of original fraction	150.85	101.06	62.47	51.29	34.54	31.63
Iodine number after the formolite reaction	34.78 116.07	43.01	22.44	23.69 27.05	24.07 10.47	19.95

As may be seen from the above, the unsaturated cyclic hydrocarbons predominate in the fractions having the lower boiling points, while the unsaturated non-cyclic hydrocarbons are predominant in the higher boiling-point fractions.

THE COMPOSITION OF MATITA ASPHALT

The researches of Prof. Charitskoff of Tiflis (*Chem. Zeit.*, 1912, p. 1,402), who examined the fractionated products of asphaltic tar and petroleum from Grosny, led him to conclude that the petroleum was a decomposition product of the asphalt. The author undertook a series of researches to establish the relation between the origin of Matita asphalt and petroleum. The petroleum that was used had a specific gravity of 0.902 at 20 deg. C. and contained 85.60 per cent C., 13.64 per cent H, 0.35 per cent N and 0.07 per cent S. On fractionation, the following products were obtained:

Up to 150 deg. C., 35 per cent by volume was distilled over, with a specific gravity of 0.721 at 20 deg. C.

From 150 to 300 deg. C., 33 per cent by volume, specific gravity, 0.817 at 20 deg. C.

Residue above 300 deg. C., 32 per cent by volume, specific gravity, 0.948 at 20 deg. C.

As can very well be seen, the petroleum fractions differ radically from the tar fractions, both in quantity and density. However, to compare them better, the saponification and iodine numbers have been determined for the oil fractions as well and are given in Table VI.

TABLE VI

Fractions	Saponification Number	Iodine Number
Up to 150°C.	1.30	1.88
150-300°C.	6.87	3.27
Above 300°C.	7.76	12.86

It is at once evident that the saponification and iodine numbers of the petroleum fractions—and hence of the oil itself—are much smaller than those of the corresponding tar fractions, indicating a very small proportion of saponifiable compounds and unsaturated cyclic and non-cyclic hydrocarbons. This constitutes the primary difference between the tar and the petroleum.

The Nastjukoff reaction was employed, as in the case of the tar, to determine the cyclic : non-cyclic ratio and the analysis of the formolites gave the results shown in Table VII.

TABLE VII

Fractions	Formolite Number	Composition of the Formolites— %C %H %S %N				C ₁₀ (by Difference)
Crude oil	22.13	64.83	11.11	4.55	4.08	15.43
Up to 150°C.	4.60	79.61	10.88	1.48	2.06	5.97
150-300°C.	21.38	77.20	9.89	1.97	1.90	9.04

Here also it is seen that the formolite members are smaller than those of the corresponding tar fractions, but that, just as in the latter case, the formolites contain the five principal elements C, H, N, S and O found in the sulphonated derivatives of all the original products which have S, N and O in their molecules.

To corroborate our theory that formaldehyde refines the petroleum, an analysis was made of the liquid residue remaining after the treatment of crude oil with formaldehyde. The analysis showed the residue to contain only C and H (85.98 per cent C and 13.39 per cent H).

The ratio between the unsaturated aromatic and aliphatic hydrocarbons was found by taking the iodine numbers of the crude petroleum and of the liquid residue from the formolite reaction. The results follow:

	Iodine Number
Crude petroleum	6.02
Liquid residue	3.75
Difference	2.27

Hence the proportion of unsaturated aliphatic hydrocarbons (3.75) is greater than that of the aromatic (2.27), which is contrary to that of the tar, where the aromatic type is predominant. In the case of the lower boiling-point fraction, this difference is even more pronounced.

CONCLUSION FROM THE RESEARCHES

The conclusions that may be derived from these researches are as follows:

1. The fractionated products of the tar are comparatively much less in quantity at the lower temperatures than in the case of the petroleum. This indicates that the original hydrocarbons in the petroleum have been subjected to a strong polymerization, which was caused by the oxygen in the air and was a gradual process, particularly facilitated by the fact that the petroleum, distributed throughout the sandy argillaceous rock, offers a very large reaction surface. Compounds of heavy molecular structure are formed in this way, which results in the elevation of the boiling point.

2. The same conclusion is reached from a consideration of the fact that the saponification numbers of the tar fractions are greater than those of the oil fractions. The oxygen in the air has polymerized the hydrocarbons, producing saponifiable compounds of various nitrogen bases, which characterize the bitumen.

3. The presence of large quantities of aromatic hydrocarbons in the tar fractions substantiates the contention that the bitumen is a product of the petroleum, for it is well known that by means of oxygen, pressure, temperature and especially time, saturated aliphatic hydrocarbons are transformed into non-saturated aromatic hydrocarbons. Such a transformation can be made to take place in the laboratory on the petroleum residues.

4. The tar products are characterized by relatively large proportions of S and N, which explains once more the molecular polymerization of the petroleum constituents.

From this study of the experimental results, it can be stated with certainty that Matita asphaltum was formed during the geologic ages by the polymerization of the hydrocarbons contained in Matita petroleum, distributed throughout the sandy argillaceous and shell-bearing marine deposits. Accordingly, its primordial origin is identical with that of the petroleum.

GENERAL CONCLUSIONS

The following general conclusions may be drawn from this general study of Matita asphaltum:

1. Matita asphaltum, found in quite large quantities

valued at 30 to 35 million francs—should constitute a source of exploitation of the first rank, because of its superior qualities as an asphalt, its high bitumen content (29 per cent), as well as for the favorable transportation conditions.

2. Matita asphaltum, when dry distilled, produces a combustible gas, which resembles that obtained from lignites in composition and yield (about 180 cu.m. per ton of bitumen).

3. The dry distillation yields about 10 kg. of $(\text{NH}_4)_2\text{SO}_4$ per ton of bitumen, 24 per cent of the N in the bitumen being recovered as NH_3 . The $(\text{NH}_4)_2\text{SO}_4$ yield is equal to that obtained from coal.

4. The coke procured in the dry distillation may be used in the refining of petroleum in place of florida earth. In any case it can be used as a ballast.

5. The tar has a specific gravity below unity and at least 120 kg. of it is obtained from every ton of asphaltic rock, or 450 kg. per ton of bitumen. This is an extraordinarily large quantity, and offers a fine source of profit, as it contains, especially in the lower boiling-point fractions, a high percentage of aromatic compounds, as well as a large amount of paraffine and hydrocarbon oils in the higher boiling-point fractions (the 200-275-deg. fraction contains 30 per cent paraffine). There is hence presented the possibility of manufacturing several explosives and there is here a precious source of paraffine, petrolatum and mineral oils of high quality.

6. The researches on the geo-chemistry of Matita petroleum and asphaltum have undoubtedly proved the latter to be a polymerization product of the former.

Steel Wizards, Past and Present

Professor Sauveur's Address Before the American Society for Steel Treating, in Which He Makes a Plea for More Important Contributions to the Art of Making Steel by American Metallurgists and Researchers

BY ALBERT SAUVEUR*

WE ARE rightly proud of our achievements, of the wonderful steel industry of our country, of our leading position as the greatest iron- and steel-producing nation in the world, but lest we forget what we owe to the steel wizards of other lands it will be salutary to recall their deeds. It will keep us from too complacent an attitude toward other metallurgical nations reporting smaller tonnage. It should stimulate in us a desire to contribute more substantially to the progress of the art in which we are interested.

We have been eminently successful. Our iron and steel industry has added vastly to the wealth of the nation. A book has been written entitled "The Romance of Steel; or, The Making of a Thousand Millionaires." Our business men, our captains of industry, our financial wizards have played their parts most successfully. Can the same tribute be paid to our scientific and technical wizards? Have they played their parts, or have they been satisfied with following the tracks of wizards of other nations? Can they be accused of parasitic tendencies?

I should first describe what I have in mind by steel wizards. I mean those men who have contributed the great basic inventions upon which the iron and steel industry is founded—men like Huntsman, Cort, Réaumur, Bessemer, Abraham Darby, Tschernoff, Osmond, Le Chatelier, Sorby, Howe—men whose discoveries, inventions or scientific contributions are epoch making.

OUR CONTRIBUTION CHIEFLY LABOR-SAVING DEVICES

Is it not true that although being by far the greatest iron- and steel-producing country we have not contributed our share of these great inventions, discoveries and scientific achievements? Is it not true that our

contributions have been chiefly of a mechanical kind, that they have consisted in the main in labor-saving devices and machinery destined to cheapen and speed up production? In this we have been undoubtedly successful and the importance of speeding up and cheapening production is not to be denied or belittled, but should we be satisfied with great advances in this direction only?

American mechanical wizards have passed through our steel plants and have left their marks, but do we not look in vain for evidences of the passage of American metallurgical wizards?

Is it not true, and is not the thought somewhat humiliating, that if all the contributions of American metallurgists and scientists to the art of making steel had never been made, iron and steel would continue to be manufactured, worked and treated practically as they are today, in reduced proportions to be sure, but of unimpaired quality? Is it not also true that if the contributions of English metallurgists and scientists were withdrawn the entire structure of the iron and steel industry would ignominiously collapse? We would have neither puddling furnaces, nor crucible steel, nor • bessemer steel, nor open-hearth steel, nor rolling or forging appliances.

We make more pig iron than any other country, but the blast furnace was neither invented nor developed in the United States. We have discarded the expensive fuel charcoal, but this was first done by the Englishman Dud Dudley in 1619. We make more coke and use more coke for iron making than any other nation, but coke was first made and first used as a blast-furnace fuel in England by Abraham Darby, who in 1735 had the inspiration of treating coal as the charcoal burners were treating wood.

More waste gases issue from our blast furnaces than in any other country, and possibly we utilize them

*Professor of Metallurgy and Metallography, Harvard University.

more thoroughly, but this has been made possible by the invention of metallurgists of other nations: by Aubertot in France, who in 1811 took a patent for the utilization of the waste gases; by James Beaumont Neilson of Glasgow, who in 1828 first suggested the use of hot blast; by Robert du Four in France and James Palmer Budd in England, who in 1833 and 1845 respectively suggested the heating of the blast by burning waste gases; by Philip Taylor in England, who in 1840 suggested the closing of the top of the furnace that the waste gases might be collected; by G. Parry of England, who in 1850 invented the bell and hopper or cup and cone as a means of closing the top of the furnace; and by the Englishman E. A. Cowper, who in 1860 introduced the use of regenerative brick stoves. We have now, I believe, a greater number of gas blowing engines than any other country, but the internal-combustion engine using blast-furnace gas was developed at Seraing in Belgium and we were at first quite reluctant to adopt it.

As notable improvements in blast-furnace operations we may claim, I believe, the automatic loading by skip cars and inclined planes and the double bell and hopper which that method requires.

We make more wrought iron than any other country, but the reverberatory puddling furnace was invented in England in 1784 by Henry Cort and the wet puddling process was introduced in that country also by James Hall and S. B. Rogers about 1830.

IN THE STEEL INDUSTRY

We have a very important crucible-steel industry, but crucible steel was first made by an English clock maker, Huntsman, in 1740, while the method we follow by which we do away with the necessity of using blister or converted steel was introduced by the Englishman Mushet in 1801.

We are making more bessemer steel than any other nation, but the bessemer converter and its necessary equipment was invented in 1856 by the illustrious Bessemer, an Englishman of French parentage, and the bessemer process was made successful by Robert Forrester Mushet, another Englishman who discovered the necessity of adding spiegeleisen or manganese in some other form.

The basic bessemer process, in which, to be sure, we are little interested, resulted from the masterly investigation and study of two Englishmen, Sidney Gilchrist Thomas and his cousin Percy C. Gilchrist, in 1878.

We make more open-hearth steel than any other country, but the regenerative furnace is not an American invention and open-hearth steel was first made by the French metallurgist Emile Martin in 1865.

We are, if I am not mistaken, making more electric steel than any other country, but we took practically no part in the development of the electric furnace for steel making, the furnace we most use being the invention of the French metallurgist Héroult.

We make more ferro-alloys and more special or alloy steels than any other nation, but the most important of these with the exception of high-speed steel we owe to the labor of metallurgists and scientists of other countries.

Our yearly tonnage of malleable castings is very much greater than that of any other nation, but the invention of the process is to be credited to the illustrious French chemist Réaumur, who described it in 1722. To him

also we owe the first scientific study and disclosure of the cementation and case-hardening processes.

We roll and forge more steel than any other nation, but with the important exception of the three-high rolling mill, rolling and forging appliances were not invented by us. The two-high pull-over grooved mill was invented by Cort; the reversing mill in 1866 by Ramsbottom in England; the universal mill is a German invention; the continuous mill was invented in 1861 by the Englishman Charles While, although it has been much improved by the American engineers Bedson and Morgan. We owe the steam hammer to the genius of two Englishmen, James Watt and James Nasmyth, and hydraulic presses to the Englishmen Bessemer and Gledhill.

We treat a larger tonnage of steel than any other country, but can we claim that the scientific investigations which have lifted the art of treating steel to such high degree of perfection are due chiefly to American metallurgists and scientists? Is it not true that with the exception of the invaluable contributions of Prof. Howe the work has been done chiefly in Russia by Tschernoff, in England by Sorby, Roberts-Austen, Arnold, Stead and Rosenhain, and in France by Osmond, Le Chatelier, Guillet, Charpy, Portevin, Chevesnard and Grenet?

HIGH-SPEED STEEL THE EXCEPTION

The discovery of high-speed steel, or, if you prefer, of the treatment imparting high-speed properties to certain steels, by F. W. Taylor and Maunsel White, I am inclined to consider as our one epoch-making contribution to the metallurgy of steel. I am well aware that some have tried to throw doubts on the novelty of this discovery, but in my opinion their contentions are not only ungenerous but unjustified. It continues to shine as the brightest American star of the metallurgical sky.

AMERICA'S ROLL OF HONOR

On a roll of honor for notable inventions, discoveries or improvements in the art of making, working or heating iron and steel or for notable and fruitful scientific contributions to that art, the following Americans are, I believe, entitled to a place:

H. H. Campbell, for designing the first tilting open-hearth furnace.

John Fritz, for his invention of the three-high rolling mill.

James Gayley, for conceiving and executing the drying of the air blown into blast furnaces.

A. L. Holley, for notable improvements in the construction of bessemer mills.

Henry M. Howe, for his invaluable scientific contributions to our knowledge of steel.

Robert W. Hunt, for his pioneer work in bessemer steel and in steel-rail manufacture.

W. R. Jones, for introducing the use of mixers in steel making.

Julian Kennedy, for notable improvements in the construction of blast furnaces and of blast-furnace equipment.

F. W. Taylor and Maunsel White, for their epoch-making discovery of high-speed steel.

Samuel T. Wellman, for notable improvements in the construction of open-hearth furnaces, for designing and constructing charging machines and other useful appliances.

Frederick W. Wood, for his introduction of the car-casting method for steel ingots.

CONCLUSION

The natural conclusion of my remarks must be a wish that we may become more prolific in steel wizards of the first order—that is, in metallurgists who will not be satisfied in merely speeding up production through ingenious labor-saving and other devices, but who will bend their energy and talent toward the discovery of new and epoch-making methods of producing, working and treating steel that we may in future, as the leading metallurgical country, contribute our full share to metallurgical progress.

Additional Technical Papers From Steel Treaters' Convention

IN THE last issue of CHEMICAL & METALLURGICAL ENGINEERING (vol. 23, p. 565, Sept. 22, 1920) there were presented brief abstracts of a few of the papers read before the first meeting of the American Society for Steel Treating. Lack of space and exigencies of publication made it necessary to hold over Prof. Sauveur's address, as well as the following abstracts gathered during the technical sessions.

FATIGUE STRENGTH OF CARBON SPRING STEEL

An important paper on the effect of heat treatment on the fatigue strength of steel was read by E. P. STENGER and E. H. STENGER, covering an investigation of spring steel made at the Sheldon Spring & Axle Works. They notice that fatigue failures are somewhat similar to failures in brittle material in that they occur with suddenness and show no deformation. Brittle metals, however, have a uniform-grained fracture, while laboratory and service failures under fatigue show a larger or smaller area of fine-grained "detail" fracture near the point of maximum stress surrounded by coarser grain.

After defining fatigue strength as the number of repetitions required to produce failure at a given stress, the authors reviewed the literature and listed the following facts which are known about the fatigue strength of steel:

First, the number of repetitions required to cause failure has a logarithmic relation to the maximum unit fiber stress. It is especially noted that there is no break in the curve at the elastic limit.

Second, the number of repetitions to cause failure depends upon the range of stress—that is to say, upon the difference between the maximum and minimum stresses imposed upon the steel. There is a certain range which will allow an infinite number of repetitions without failure, but this range narrows as the maximum stress increases.

Third, the fatigue strength is independent of the speed up to 2,000 per minute.

Fourth, rest and repeated tempering below A_c , does not increase the endurance of unhardened steel.

Fifth, cold work affects the fatigue strength variously.

Sixth, endurance of metal shows a maximum when the metal is held at from 300 to 400 deg. C.

Seventh, the endurance of carbon steels is greatest with hardened eutectoid steel.

The authors describe in detail the heat treatment and preparation of samples in their research upon a carbon spring steel containing the following analysis: Carbon 1.03 per cent, manganese 0.45 per cent, sulphur 0.025 per cent, phosphorus 0.026 per cent. They conclude that the shape factor is of great importance because it gives a non-uniform disposition of internal loads with stresses highly concentrated at certain points. Again, the condition of the external surface, whether impaired by the gases of the heat-treating operation or ground clean, has an enormous influence upon the fatigue strength of the sample. Results of their systematic tests on this carbon steel are plotted in Fig. 1, from which many inferences may be drawn.

FIG. 1. ENDURANCE OF CARBON SPRING STEEL AFTER VARIOUS HEAT TREATMENTS

Two curves are shown for the 1,700 quench. The authors are of the opinion that a parabolic curve such as the dotted one may be more reliable than the full line following the points more closely, since one of the bars drawn at 450 deg. F. withstood nearly 8,000,000 repetitions. They also remark that it is very hard to get test pieces from a 1,700 quench free from a multitude of finest hardening cracks.

A complete study of their results from all angles appears to show that the maximum fatigue strength of this steel varies both with the quenching and with the drawing temperature. Apparently the sample has the best resistance when it has been quenched from just above A_{c_m} , which obliterates the previous grain structure. They also found that bars hardened from this temperature showed the highest strength after drawing to a structure of troostite. A final important conclusion of the authors is that re-shaped springs fail very quickly; in other words, a duplication of regular heat treatment on springs that have been used for some time actually hastens fatigue failure.

FIG. 2 COST OF MAINTAINING FURNACES AT VARIOUS TEMPERATURES AND WITH DIFFERENT FUELS

ECONOMY IN ELECTRIC FURNACES

E. F. COLLINS, of the General Electric Co., presented a paper on "Relative Thermal Economy of Electric and Fuel-Fired Furnaces," containing the diagram reproduced in Fig. 2. This was plotted from data figured for perfect combustion with 50 per cent excess air, and regards nothing except cost of heat units involved.

DATA FOR CURVES

Points Figure 1 Deg. F.	Suitable for	Radiation Loss per Cent
400	Baking	15
1600	Heat treating	20
2300	Forging	30
2800	Melting	40

Source of Heat	Calorific Value	Rate
Coal	13,000 B.t.u. per lb.	\$10.00 per ton
Electricity	3,415 B.t.u. per kw. hr.	9.81 per kw. hr.
City gas	5.93 B.t.u. per cu ft.	1.00 per M
Fuel oil	19,000 B.t.u. per lb.	10 per gal.
Anthracite	12,000 B.t.u. per lb.	10.00 per ton
Bituminous	12,550 B.t.u. per lb.	5.00 per ton
Natural gas	1,100 B.t.u. per cu ft.	30 per M

As a matter of fact, electric power is actually cheaper per B.t.u. at higher temperature, although convenience, ease in handling, automatic regulation, low repairs and overhead have favored electric heating even at low temperatures. Metallic resistor furnaces are therefore very popular in enamelling ovens, core-baking ovens, drying and annealing furnaces and hardening furnaces. Arc, induction, or carbon resistor furnaces are also widely applied to forging and melting furnaces; in large installations their relative economy in cost of heat is less than inferred from the curves owing to the possibility of regenerating heat lost from carbon-fired furnaces in products of combustion.

DETERMINING COMPARATIVE EFFICIENCY OF COMBINATIONS OF ALLOYS IN STEEL

"A Suggested Method for Determining the Comparative Efficiency of Certain Combinations of Alloys in Steel" was given by J. D. CUTLER, metallurgist for the Climax Molybdenum Co. His thesis is that if some value be assigned to the effect of a certain alloy addition (merit index), and this value be divided by the

cost of the additions, then the quotient will be a figure which represents relatively the comparative value of the combination under discussion. Merit index should be proportional to the ability of steel to withstand work done upon unit quantity—i.e.,

$$\text{merit index} \propto \text{work} \div \text{mass}$$

Work done to break a standard tension test piece is equal to the average pull times the distance it works through, the latter factor being of course the elongation. Lacking the complete stress-strain curve for integrations, the author assumes the average of elastic limit and the ultimate strength to be the average pull. That is to say, his expression proportional to the work is $\frac{1}{2} (e.l. + ult.)$ elongation. Furthermore, since a piece which suffers pronounced necking usually has the deformation strictly localized, while a piece which breaks with little necking is ordinarily stretched throughout its entire length, the mass of deformed material is roughly proportional to $100 - \text{reduction}$. Hence, Mr. Cutter proposes the formula

$$\text{Efficiency} = \frac{\text{merit index}}{\text{expenditure}} \\ \frac{\frac{1}{2} (e.l. + ult.) \times \text{elonga.}}{100 - \text{red.}} \\ : (\text{lb. ferro} \times \text{unit cost})$$

which may be utilized to determine the relative economy of two alloys which might be used for the same purpose.

ELECTRICAL HEAT TREATMENT OF STEEL

H. P. MACDONALD, vice-president, Sneed & Co., in his paper, entitled "Electrical Heat Treatment of Steel," described an electrical resistance method he has been using to heat-treat long rods and tubes, particularly thin-walled nickel-steel tubing for lances and airplanes. When using fuel-fired furnaces soaking is necessary to insure uniform heating, and the tendency is toward too long a soaking time with its attendant surface deterioration and crystalline growth. Non-uniform heating is also a prime cause of warping. To obviate these difficulties the author has rigged up a pair of grips to clasp the ends of the pipe or bar to be treated, held vertically between them. A heavy current is thrown through the piece, using the grips as contact pieces, very much after the action of an electric butt welder. As the pipe or bar heats it expands, and this elongation is indicated by a pointer, whose movement is geared to the upper grip. When passing through the transformation the combination of volume change and heat absorption halts the movement of the pointer, and even reverses its motion; when finally transformed the pointer again resumes its movement. Shortly thereafter both grips are released, interrupting the electric current and dropping the bar into a vertical quenching tank immediately below. Obviously, quenching of pipe might be done while still in the grips by an internal stream of oil or water. About $1\frac{1}{2}$ in. is unhardened and wasted, where the copper grips were in contact with the piece. Pieces may also be annealed in the same machine by a simple modification in the procedure. The method is rapid—requiring only a minute to heat each piece; it obviates scale formation, decarbonization, crystallization and warping; it is self-indicating; and finally it is cheap, due to the efficient application of the energy. On the other hand, it is limited to straight pieces of uniform cross-section.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Copper and Its Alloys.—For deoxidizing and refining copper and its alloys, a copper cartridge containing potassium phosphide is first added to the metal heated above its melting point to convert the impurities, silicon, arsenic and protoxide of copper into phosphorus compounds; then, at a higher temperature, a second copper cartridge, containing one of the metals of the alkaline earths or lithium, is added for the purpose of decomposing the phosphorus compounds, which burn at the expense of the alkaline-earth metal, and the oxides formed float on the surface of the copper. (Br. Pat. 142,441—1919. A. STRASSER, Rorschach, Switzerland, July 7, 1920.)

Glucose, Furfural, Methyl Alcohol.—In the manufacture of furfural, methyl alcohol and easily fermentable glucose from materials containing cellulose, a larger yield is obtained by the addition of a small quantity of an acid or acids besides the acid required for the conversion purpose. Hydrochloric, sulphuric, sulphurous and hydrofluoric acids are suitable, or acid salts, or salts decomposed by excess of acid or hydrolytically—e.g., chlorides of magnesium, calcium, aluminum, zinc and manganese. When several additional acids are used, excess of one ingredient is preferable. When hydrochloric acid is employed as the conversion agent, a mixture of sulphuric and sulphurous acids is preferred as catalyst. The ligneous material is mixed with one-half to less than an equal volume of water in order to prevent formation of non-fermentable sugars. After the vapors from a preliminary steam-treatment in an autoclave have been removed, the requisite acids are introduced, the conversion acid being added in sufficient quantity to leave the treated material so that it can readily be disintegrated, and the pressure is raised to 7 or 8 atmospheres. Steam may be employed at lower pressure by the addition of special "protective" substances—e.g., metallic oxides. On completion of the conversion process, the contents are rapidly cooled by evacuation into a cooling-chamber, where the furfural is condensed. Any furfural or methyl alcohol remaining in the residues is removed by suction or by blowing in steam. The sugar solution is obtained from the residue by lixiviation. (Br. Pat. 142,480—1919. A. CLASSEN, Aachen, Germany, July 7, 1920.)

Ammonia.—In making mixtures of hydrogen and nitrogen for preparing ammonia by the Haber process, a mixture of air, oxygen and steam, or of air and steam is passed through coke in a gas-producer heated to 650-850 deg. C. at a rapid rate to avoid formation of much carbon monoxide. The resulting gas is treated to remove sulphur compounds, oxygen, water, etc., and to transform carbon monoxide to carbon dioxide, which is removed by treatment with ammonia. If necessary, hydrogen may be added to bring the mixture to the requisite composition. The coke is prepared by carbonizing coal which has been washed to remove iron pyrites

and mixed iron oxide and calcium carbonate or other sulphur retainer, in a preliminary producer A. Air is introduced through openings D, and the gas withdrawn at E is purified and used for heating and power purposes. The hot coke is fed into the main producer B formed of a casing of sheet iron with a lining of hollow glazed bricks of silica in which passages are formed for preheating the gases. Owing to the low temperatures used and the rapid current of gas, the ash does not clinker, and much of it is carried by the gas into a separate settling-chamber (not shown). The hot gases are passed over limestone, magnesia, or magnesium limestone in a vessel K heated to about 700 deg. C. to remove sulphur compounds, are treated to remove dust and tar, and mixed with steam and passed over suitable known catalysts, such as iron oxide at about 450 deg. C. to convert carbon monoxide into carbon dioxide with formation of hydrogen, and to convert carbon bisulphide

PRODUCER FOR NITROGEN-HYDROGEN MIXTURES

into sulphuretted hydrogen, which is removed by passage over iron oxide or by other means. The gases are mixed with air and passed over a low-temperature catalyst as described in Specification 127,609, to transform the residual carbon monoxide into carbon dioxide, and are compressed to 5-15 atmospheres to separate water, which is passed through a heat-exchanger and formed into steam at ordinary pressure and used in the earlier part of the process. Carbon dioxide is removed by treating the gases in towers O¹, O² with water and ammonia from the Haber plant or from another source. The ammonium bicarbonate formed is treated with sodium chloride to form sodium bicarbonate, or is passed over calcium sulphate to form ammonium sulphate. The towers may contain calcium sulphate to form ammonium sulphate directly. The gases are passed through a tower O³ containing packing, water, and iron or copper to remove oxygen, and are compressed at A to 100-150 atmospheres. The water which separates is used to wash, in the tower T, the circulating gases in the Haber plants to remove the last traces of ammonia. The gases are mixed with the circulating gases, washed with water, and dried by passage through caustic soda or potash solution and over solid caustic potash or sodium wire. The final trace of carbon monoxide may be removed by adding oxygen and passing over a low-temperature catalyst as described in the above-mentioned specification, the carbon dioxide formed being removed by adding the gases to the catalyzed gases under pressure before removal of ammonia. (Br. Pat. 142,874—1919. J. HARGER, Liverpool, July 14, 1920.)

Current Events

in the Chemical and Metallurgical Industries

C.W.S. Officers Appointed

Results of the examinations for commissions in the Regular Army are now being announced. The following appointments as commissioned officers in the Chemical Warfare Service have been announced:

To be Majors, B. A. Brackenbury, San Francisco; A. M. Heritage, Washington, D. C.; H. H. Stickney, Jr., Lakehurst, N. J.

To be Captains: E. B. Blanchard, Charleston, S. C.; James H. Bogart, Boston; D. B. Bradner, Edgewood, Md.; Arthur Cobb, Lakehurst, N. J.; Harold Guiteras, Tyrone, N. M.; Stroud Jordan, Brooklyn; Lewis Latimer, Washington, D. C.; L. M. McBride, Chicago, Ill.; John G. McCoy, Edgewood, Md.; John A. MacLaughlin, Washington, D. C.; Earl Poppe, Fort Sam Houston, Tex.; Harry Scarborough, Cornwall-on-Hudson, N. Y.; Edward C. Thompson, Edgewood, Md.; William W. Wise, Camp Benning, Ga.; O. E. Roberts, Jr., Washington, D. C.; Edward Wolesensky, Cliffside, N. J.; Chester M. Scott, Edgewood, Md.

To be First Lieutenants: Joseph F. Battley, Edgewood, Md.; H. B. Bramlet, Camp Funston, Kan.; Guy L. Chamberlin, Lakehurst, N. J.; Patrick F. Craig, Lakehurst, N. J.; L. A. Elliott, Edgewood, Md.; Edwin L. Frederick, Catonsville, Md.; Arthur J. L. Hutchinson, Taft, Cal.; Harry A. Kuhn, Edgewood, Md.; Harry R. Lebkicker, Lakehurst, N. J.; George A. Mackay, Edgewood, Md.; Paul G. Miller, Alton, Ill.; David P. Miles, Redding, Cal.; Charles S. Moyer, Governor's Island, N. Y.; John E. Ott, Ocean View, Va.; Murray C. Wilson, Chicago; Howard Stokes, Lakewood, N. J.

To be Second Lieutenants: Fred M. Henley, Edgewood, Md.; Maurice E. Jennings, Seymour, Ind.; Harold A. Pelton, Camp Lewis, Washington; Paul R. Smith, Edgewood, Md.; M. E. Webber, St. Louis; Frank B. Gorin, Chicago; Shelby N. Griffith, Camp Dix; Ralph H. Tate, Owosso, Mich.

Further appointments are to be announced, but General Fries has been advised of the total number which have passed, which leaves thirty vacancies still to be filled. Additional examinations will be held.

Chemical Advisory Committee Named

General Amos A. Fries, head of the Chemical Warfare Service, states that he expects to lean heavily upon the committee of the American Chemical Society which is to co-operate with the Chemical Warfare Service in an advisory capacity. Charles H. Herty, who is to be chairman of the committee, has conferred at length with General Fries as to the assistance which the committee will be expected to give. The committee is to be divided into four sections. One is to be composed of research advisers, another of development advisers, a third of production advisers and a fourth physiological investigation advisers. The following personnel for these groups has been recommended:

Research advisers—W. D. Bancroft, Cornell Uni-

versity; R. C. Tolman, Fixed Nitrogen Research Laboratories, Washington, D. C.; A. B. Lamb, Harvard University; E. P. Kohler, Harvard University.

Development advisers—F. M. Dorsey, National Lamp Works, Cleveland; W. K. Lewis, Massachusetts Institute of Technology; L. T. Sutherland, New York.

Production advisers—L. C. Jones, National Aniline Co.; C. L. Reese, E. I. du Pont de Nemours & Co.; William H. Walker, Massachusetts Institute of Technology; Bradley Dewey.

Physiological investigation advisers—Reid Hunt, Harvard University; A. S. Loevenhart, University of Wisconsin; Julius Stieglitz, University of Chicago.

Nebraska Potash Situation Improves

Cessation of rains in Nebraska during recent weeks has greatly improved the potash situation at the evaporation plants in that state. The abnormal amount of rain earlier in the year had flooded the entire country and had so diluted the brine that evaporation costs were very high. A much larger recovery is being obtained from the same amount of fuel.

Despite rumors to the contrary, no plant in the Nebraska district has been closed, it is stated at the office of the United States Potash Producers' Association in Washington.

A recent report from France to that organization is to the effect that car shortage, strikes and the uncertainties pending the probable nationalization of the Alsatian mines makes it improbable that there will be any exports of Alsatian potash in the near future. As a matter of fact, delivery has not been completed on orders taken in the United States a year ago. It is not expected that the Alsatian production will offer any particular competition to Germany for a long time to come.

News of Alpha Chi Sigma

L. I. Shaw has resigned as national secretary and treasurer of the Alpha Chi Sigma fraternity. He is to be succeeded by B. H. Ball of Highland Park, Ill. Mr. Shaw has been appointed to succeed the late E. U. Titus as vice-president of the fraternity.

Mr. Shaw has held the office of secretary and treasurer since 1912. During that time he has seen the membership of the fraternity increase from 700 to 3,500. When he began his work as secretary there were seventeen chapters. The fraternity has expanded until it has become truly a national organization with thirty-one chapters. A chapter is now in existence at practically all the leading universities in the country.

The *Hexagon*, the official publication of the Alpha Chi Sigma fraternity, is to be published monthly in the future. Heretofore it has been appearing quarterly. Paul D. V. Manning, who recently succeeded R. S. McBride as editor of the *Hexagon*, will continue in charge of the paper.

Method for the Quantitative Measurement of Consistency

Some time ago the U. S. Bureau of Standards developed a method for the quantitative measurement of plasticity. This was described in Scientific Paper 278, and proved of great commercial value. Papers on the application of the method to paints have appeared in the *Proceedings* of the American Society for Testing Materials in 1919 and 1920.

The general method is to force the substance under investigation through a capillary tube by means of air pressure. The pressure is kept constant during any one run, but runs are made at various pressures with the same substance. The two values which are deduced from the readings thus obtained determine the consistency, but do not determine the plasticity as defined for mortars and plasters. In this latter sense, as described in Technologic Paper 169, plasticity depends upon other factors besides consistency.

At the present time an investigation is in progress at the Bureau in regard to the application of the plastometer, as used for paints, to adhesives such as starches and dextrines. This work is being done by an industrial associate under the general direction of a member of the Bureau's staff. The indications are that the quantitative measurement of the consistency of adhesives of definite concentration will do much to enable manufacturers to predict the exact behavior of their products in service.

Pulp and Paper Developments in Newfoundland

Grants to a British and a Norwegian pulp and paper company at the last session of the Colonial Legislature are indicative of important developments in the pulp-wood timber resources of Newfoundland. Reports from St. John's, N. F., state that the British concern will locate its plant half way up the west coast at Bonne Bay, where there are large tracts of spruce and fir together with ample water facilities for power and transportation. The Norwegian company's site will be at Bonavista Bay, on the east coast.

At present the only pulp and paper mills on the island are at Grand Falls, established by the Anglo-Newfoundland Development Co. some years ago to supply the Northcliffe papers in England.

Negotiations are under way to exploit large tracts of spruce on the south coast. The extensive timber holdings of the Reid Newfoundland Co. are also expected to be utilized for pulp making in the near future. Another project contemplated is the establishment of paper and pulp mills, sawmills and veneer mills for the manufacture of birch into boxes and barrels at St. George's, on the west coast.

Philippine Vegetable Oil Companies Combine

It is reported by the *San Francisco Journal of Commerce* that the Philippine properties of the Visayan Refining Co., the Rizal Refining Co. and the Philippine Refining Co. have been consolidated into one company to be known as the Philippine Refining Corporation, with a capital of 20,000,000 pesos. Lever Bros. are large subscribers for the stock of the new corporation and Lord Leverhulme will be chairman of the board of directors. Lever Bros. are the largest consumers of coconut oil in the world and will monopolize practically the entire output of the consolidated company.

Anaconda to Manufacture Fertilizer

The Anaconda Copper Co. has decided to embark, with a plant of considerable size, in the manufacture of a super-phosphate fertilizer. It is the intention to market this fertilizer in the Middle West. A. E. Wells has just completed a survey of the markets for this type of fertilizer and is of the opinion that an outlet can be found for it throughout the farming regions of the upper Mississippi Valley.

Waste gases will be used for the manufacture of sulphuric acid. The phosphate rock will be obtained in Idaho and Montana. It is an intention of the Anaconda company to prepare a fertilizer which will contain 48 per cent of available phosphoric acid. In this way, it is believed, it will be possible to overcome the high transportation charge so as to enable the product to compete with the ordinary Eastern-made material which contains 16 per cent of available phosphoric acid.

Use of Etched Balls in the Brinell Test of Hardened Steels

At the request of the chairman of the Hardness Committee of the National Research Council, the device described by Hulgren for obtaining impressions with etched balls in the Brinell hardness test was examined in detail by the U. S. Bureau of Standards. Briefly this method of testing consists in etching the steel ball with which the impression is made for a minute or so in a weak (2 per cent) alcoholic-nitric acid solution, after which the test is performed as usual. If the specimen the hardness of which is to be determined is in a polished state, the impressions with the etched balls are very distinct, while those with an unetched ball are almost invisible when viewed at certain angles. If the specimen to be tested is not polished, however, preliminary etching of the ball does not appear to be of much advantage.

Wood Alcohol Causes Death of Nine Men

There was no admixture of poison gas with the alcohol which caused the death of nine employees of Edgewood Arsenal. General Amos A. Fries, head of the Chemical Warfare Service, investigated the matter personally immediately after the case was reported. General Fries found that some liquor had been secured off the arsenal grounds. The men who brought in the intoxicants gave a "party" to a number of their fellow-workers. The liquor soon ran out and to meet the demand for additional supplies resort was had to a steel drum of wood alcohol in one of the laboratories. Nine men drank the wood alcohol with fatal results.

The Problem of Scientific Abstracts

The Royal Society of London has called a conference in London beginning Sept. 28 to consider the future of the International Catalogue of Scientific Literature. Financial problems confront this publication and it is uncertain what further steps are necessary for its continuance or modification. American representatives will speak for the National Research Council, the Smithsonian Institution and the National Academy of Sciences. R. M. Yerkes and S. I. Franz will represent the Research Council; L. E. Dickson, professor of mathematics, University of Chicago, will represent the National Academy of Sciences; and L. C. Gunnell will represent the Smithsonian Institution.

Permeability of Concrete

Some preliminary tests have been made by the U. S. Bureau of Standards of a new apparatus for determining the rate of penetration of water through concrete and other permeable materials. The apparatus is so constructed that it is not necessary to mold the test piece in any particular shape, but any slab having one fairly smooth face may be tested. Only a few seconds are required for placing and adjusting the test specimen. This will permit specimens to be cut from walls or other portions of structures for tests. Tests so far made, while more in the nature of a try-out of the apparatus than the materials used, have furnished some rather interesting results.

In the following table the results of tests on samples of building stones from various quarries, as well as on some mortar and concrete specimens, are shown. The specimens varied from 1½ in. to 2½ in. in thickness and 60-lb. water pressure was applied over an area of 25 square inches.

Test Specimen	Absorption, in 24-Hr., per Cent	Thickness, In.	Time Required for Penetration Through Wat.
Limestone 50	5.80	1½	10½ min.
Limestone 715	5.10	1½	11 min.
Limestone 8907	4.40	1½	19 min.
Limestone 9c	4.60	1½	2½ min.
Limestone 14F	3.81	1½	20 sec.
Limestone 5G	3.48	1½	1½ min.
Sandstone	5.56	2½	10 sec.
1:6 portland cement mortar	7.8	2	3½ hr.
1:1½:2 concrete	5.8	2	Did not fail in 24 hr. When broken through water had penetrated

These results appear to bear out conclusions previously drawn in the Bureau's investigation of the durability of concrete in alkali soils that there is no apparent relation between absorption and permeability.

While considerable work must be done to standardize the method of making the permeability tests, it appears that this apparatus will assist in studying with a minimum of effort an important characteristic of concretes which has in the past been generally ignored, due to lack of suitable apparatus.

The Artificial Silk Industry

The end of June, 1920, saw the entry of the United States on a notable scale in artificial silk manufacture. The scarcity of the natural product and the increased demand for the artificial product have created a new industry.

As artificial silk was first invented and developed in the chemical laboratories abroad, Europe naturally took the lead in its production. In 1911, when artificial silk and its manufactures were first shown as a separate class on the import schedule, out of 1,947,423 lb. valued at \$3,279,559 all but 12 lb. came from Europe. England was the chief shipper, followed by Germany, Austria-Hungary, Belgium, France and Switzerland.

The war greatly reduced the European production of artificial silk, stopping work in all the plants in Belgium and the invaded portion of France, while the shortage of labor and chemicals affected the industry in other countries. The great Tubize Co. in Belgium, in operation since 1900, with a pre-war production of about 10,000 lb. daily, dismantled its factories and buried or otherwise concealed its lead, copper and other metal fixtures, its electric motors, generators, wiring and belting, and escaped German confiscation. Shortly after the war closed, this factory was operating at the rate

of its pre-war output, and showed a profit for the fiscal year of 1919 of 4,178,264 fr. This plant uses the Chardonnet process and is about to commence making silk by the viscose process. Recently it contracted with an American syndicate to erect a large artificial silk factory in the United States with an initial capital of \$5,000,000.

Artificial silk exports from the United States were not shown separately in the report schedule prior to the fiscal year 1917. In that year \$857,318 worth of American-made products were distributed to all parts of the world. Europe received \$395,990 of this amount, North America \$260,216, South America \$56,653, Asia \$19,033, Oceania \$118,850 and Africa \$6,576.

Prior to the war only the viscose process for making artificial silk had been used in the United States and before 1914 the bulk of the yarns used by American manufacturers was imported from Europe. In 1919 there were only two concerns in the United States actually producing artificial silk yarns on a commercial scale, one located at Marcus Hook, Pa., and one at Roanoke, Va. The latter is said to be producing 150,000 to 200,000 lb. per week at the present time. The extraordinary demand for this product has led to the recent formation of other corporations with abundant capital to establish large factories. Each of these large concerns is said to be allied with the largest producers in France, England and Belgium.

There are three varieties of artificial silk entering into our imports, according to their origin. They are classified as cellulose silk, collodion silk, and glue or gelatine silk. The products of the various processes differ from one another and from the natural silk in chemical composition. The artificial silk excels the natural product in luster only. France succeeded in making artificial silk bags to hold powder and wove certain parts of gas masks used on the front during the war. A Lyons factory is now producing a product called silk cellulose to be used in the manufacture of velvets, jerseys, satins, draperies, linings and other goods. The artificial silk textiles are also used in upholstery and carpet manufacture. Serviceable imitation horsehair hats are made of artificial silk braids, and novelties of this material appear each season in the millinery trade.

Non-Ferrous Metallurgical Research

Thanks to facilities afforded by one or two leading manufacturers, the association formed in Birmingham, England, for carrying on research work in connection with the non-ferrous metals is now getting into practical work, says the *Engineer* (London) of July 23. A specially installed electric furnace has been placed at the disposal of Prof. Thomas Turner, of the university, for experimental work upon the casting of brass and copper ingots. The furnace, which is itself in the experimental stage, has been erected on the firm's premises, and tests are being made which, it is hoped, will solve problems that have long puzzled the brass-founders, particularly respecting ingot blow-holes. Another local firm has placed a laboratory at the disposal of the association for twelve months, and this concession is likely to prove of distinct aid to research. Though the association is now eighteen months old, it is practically unhoused. Research work can be delayed only at serious risk to the development of the industry's welfare.

British Cotton-Growing Research Association

The British Cotton-Growing Research Association has issued a report covering the first nine months of the work, of which a short abstract was lately published in *Science*. In order to co-ordinate the work of its various departments a property known as The Towers has been purchased for its headquarters in East Didsbury, near Manchester. Heads of the following departments either have been or are about to be appointed: Chemistry, physics, colloids, botany and technology. Dr. E. A. Oxley of Cambridge and Sheffield Universities has been named head of the department of physics; Dr. J. C. Withers has been appointed to direct the abstracting and indexing of technical information in the records bureau. It is said that information is so scattered that it will be some time before a comprehensive idea can be given of the work accomplished in the past.

The report adds that the chief aim will be to arrive at the principles or theory underlying the practice of the industry, leaving the application of the theory to those actively engaged in the industry. Applied research cannot, however, be entirely omitted, especially in respect of such matters as may be considered beyond the resources of individual firms.

In co-operation with the Empire Cotton-Growing Committee a joint committee has been appointed, with the immediate object of granting scholarships to graduate students, so as to secure a supply of trained men for the future. Three botanical research studentships have already been established. The total number of individual members of the association is 1,408. The income for the year, including £6,750 government grant, amounts to £17,150.

Canada's Paint Industry

More than \$17,000,000 worth of paints and varnishes were manufactured in Canada during 1918, according to a report published recently from the Mining, Metallurgical and Chemical Division of the Dominion Bureau of Statistics. In the same time Canada imported more than \$6,000,000 worth of paints, varnishes and materials used in the paint and varnish industry. Of this sum \$1,000,000 was spent in gums, nearly \$2,000,000 in white zinc and more than \$1,000,000 in rosin. Forty-five establishments were operated during the year with an aggregate capital investment of \$15,784,610.

The report gives detailed information regarding the numbers and compensation of the officers, superintendents, clerks and wage-earners according to classes, and also shows the quantities and values of materials used in the manufacture of the products, which are listed by quantities and values.

This report, one of a series of advance chapters dealing with the production of chemicals and allied products in Canada during the year 1918, is available for free distribution to those interested. Requests should be addressed to the Dominion Bureau of Statistics, Ottawa.

U. S. Bureau of Mines Establishes Experiment Station at Rolla, Mo.

The Mississippi Valley Experiment Station of the U. S. Bureau of Mines has been located at the Missouri School of Mines and Metallurgy, Rolla, Mo. A conference of operators of the Mississippi Valley section will be held in the Chamber of Commerce Building, St. Louis, Oct. 9, to discuss problems that should be considered by the new station.

Investigation of Combination of Aluminous and Siliceous Bond Clays Used in Making Crucibles

During the war the making of glass pots, crucibles and various other special refractories was seriously interfered with, owing to the lack of certain clays formerly imported from Germany, particularly plastic bond clay known as Gross Almerode. The Bureau of Standards conducted an investigation with the object of finding an American clay or combination of clays which could be used as a substitute for the German material. It was found that a mixture of three parts of Arkansas kaolin and one part of No. 4 Kentucky ball clay formed a satisfactory substitute for the Gross Almerode clay, and this combination was used extensively during the war. This investigation is now being extended and will soon be completed. Sixty small pots have been made and will be subjected to the corrosive action of various kinds of glasses. It has been found that when used with 50 per cent grog and Arkansas kaolin it has even a lower shrinkage and higher porosity than the German clay. These are very valuable properties for clays to be used in the making of glass-house refractories, and present indications are that this clay will be extremely important for this particular purpose.

Movement of Nitrate Through Panama Canal

The movement of nitrate of soda through the Panama Canal during July totaled 32,101 tons. Of that amount 14,801 tons was consigned to American ports. The remainder went to European ports.

Book Reviews

THE ORGANIZATION OF INDUSTRIAL SCIENTIFIC RESEARCH. By C. E. Kenneth Mees, D. Sc., Director of the Research Laboratory of the Eastman Kodak Co., Rochester, N. Y. Pp., ix + 175; 10 figures. New York and London: McGraw-Hill Book Co., Inc., 1920. Price, \$2.

This book is intended by its distinguished author as a contribution to the study of the best methods of organizing research work for industrial purposes and of the conditions under which such work should be conducted. It gives consideration to general principles, but, in addition, reflects throughout its nine chapters the effort of the author to be as definite in statement as the nature of the subject will allow. The following matters are discussed serially: Types of research laboratories; co-operative laboratories; the position of the research laboratory in an industrial organization; the internal organization of industrial research laboratories; the staff of a research laboratory; the building and equipment of the laboratory; the direction of the work; and the design of a research laboratory for a specific industry. There is also a select bibliography, which is comprehensive and usefully valuable for reference.

The scope of the book and the method of presentment employed in its preparation are excellent, and both industrialists and scientific workers will find it interesting and informative. It is thought, however, that most of its readers will regret that the author has given such brief treatment to certain of the aspects of the subject, that no attention is accorded to the co-ordination of research, and that more space is not devoted to the systematic collection and distribution of scientific information, especially research findings. The book is intended principally for manufacturers who have had no occasion to consider in detail the planning and executive control of a research department; and while most manufacturers who will decide to read

it will be convinced in advance of the need for research in their specific industries, the author has passed by an opportunity to demonstrate in review the economic and social benefits of properly planned, well directed scientific inquiry, for the use of executives who may need this material for educational purposes.

W. A. HAMOR.

PERSONNEL ADMINISTRATION; ITS PRINCIPLES AND PRACTICE. By *Ordway Tead* and *H. C. Metcalf*. 538 pp., index. New York: McGraw-Hill Book Co., 1920.

During the past half-century a complete change has come about in the viewpoint of industrial administration, a change so gradual that few people have any clear realization of its completeness. The change is further masked by the fact that it was theoretically unnecessary. What has happened is that actual practice has come to approximate the general principles of social relations which have long been publicly proclaimed. With the new viewpoint and practice has come a new literature; countless articles on how to prevent accidents by means physical and metaphysical, how to conserve health, how to prevent fatigue, how to do things with the least effort, how to pick the right man for the right job and how to make him satisfied with it after he has it, first began to trickle into periodical literature and then swelled to a flood that has led to the founding of journals primarily devoted to such matters. Some of this literature is the result of the application of trained minds to industrial and social problems, some of it is a hybrid of sentimentalism and half-baked social theories, and a modicum of it is little better than charlatanism run riot. There has been great need for the gathering together of what has appeared, the separation of the wheat from the chaff, and the presentation of that most worth while in orderly and systematic fashion so that the busy man (and busy man is almost a synonym for the worker in industrial fields nowadays) can easily acquire a grasp of the progress that has been made. This is what the authors have tried to do in their volume on personnel administration, and on the whole they have succeeded very well. Ten years from now, it is quite possible, their views will be regarded as somewhat conservative and old-fashioned; ten years ago they would have been regarded as dangerously radical and socialistic. In not a few quarters today the fact that the authors have ventured to quote at times from the *New Republic* will be taken as sufficient indication that they are not worthy of consideration by conservative business men.

The field of their task is defined by the authors as setting forth the principles and the best prevailing practice in the field of the administration of human relations in industry, and they take up *seriatim* the personnel department, employment methods, health and safety, education, research (job analysis, specifications, etc.), rewards, administrative correlation, and joint relations. In a book of this character it is not reasonable to expect anything new beyond the integration of material, much as writers in the *Literary Digest* collate a number of quotations into a complete story. In both cases the result is almost certain to be interesting and helpful; the only opportunity for criticism lies in the choice of material and the relative amount of space accorded to it. Thus the seven pages devoted to safety may be regarded by some as all too little for its importance, yet into that space the authors have compressed an admirable summary of the principal methods for accident prevention, and the economic pressure of workmen's compensation laws puts sufficient emphasis on such work in the average plant so its importance does not need to be stressed. The health of the workers is accorded twice as much space, fatigue being considered at some length, but with the usual defect of regarding it as chiefly a physiological problem, the mental factor being underestimated, though possibly the authors may have it in mind in suggesting the value of changing jobs. Much of the longer chapter on standards of physical working conditions is really a more extended discussion of the health of the worker, and accident prevention is again mentioned. The

section on education takes up the training of executives, foremen and workers and goes on to consider the company magazine from its educational and other aspects, which leads naturally to the arousing of interest in work, to which twenty-five pages are devoted. Transfer and promotion are taken up from their educational aspects but in their development lead naturally into the next division, which the authors have designated as research—an inclusive term intended to cover the analytical and statistical study of the measurable factors in personnel problems. In their consideration of job analyses and job specifications, measurement of turnover and labor audit the authors display a humanness of view that is refreshing in comparison with the coldly statistical attack of most practitioners of scientific management. The question of rewards, wage payment, plans and methods, and meeting the industrial risks, is covered in fifty pages, which is all too little in proportion to its importance to the worker, but this is a topic which it is hard to make interesting to anyone except the recipient of the reward. The treatment is, on the whole, good, though the authors seem to share in some degree the common fallacy that pay can largely be based on what it costs a man to live rather than on an adjustment of shares in the value of the joint product which will insure a proper balance of labor and capital supply in the conduct of industry. So much discussion has been devoted to wages in the history of industry and so little of real enlightenment has emerged that the authors are perhaps wise in being brief. From this point the book grows steadily more "advanced." The boards of directors are still few that would accept the organization chart shown on page 375, where the production manager and personnel administrator are shown as co-equal in plant administration, and a subsequent chapter on the business value of the collective bargain, impartial as it is, will be regarded by many as too sympathetic to the employee. The chapter on national industrial councils will be interesting and useful to the many people who have been unable to get any clear comprehension of what has been afoot in England in the past few years, even though they may be inclined to raise more objections than the authors do to the general adoption of the plan in America. An unusually full index adds much to the usefulness of this valuable and timely volume.

T. T. READ.

Personal

H. M. BOYISTON, of Sauveur & Boylston, has accepted an appointment to the chair of metallurgy in the Case School of Applied Science, Cleveland, Ohio.

A. W. MANGUM has resigned as chemical supervisor of soap making in the Procter & Gamble Co. to accept a position in the chemical division of Lever Bros. Co., Cambridge, Mass.

PERRY N. MOORE has recently become associated with Parker C. McIlhiney, consulting engineer, of New York City.

KARL C. PARRISH, of Cartagena, Colombia, South America, a prominent engineer in the development of mining and business properties in that district, is in Chicago and other Western points on an extended business trip. Among other activities he is the representative in Colombia for Fairbanks, Morse & Co.

C. PRICE-GREEN, commissioner of the Canadian National Railways, spent the week at the Chemical Exposition in the interest of the development of Canadian resources.

Dr. S. P. SADTLER left this week for a trip to the West to make a study of the brine potash industry. He will be gone several months.

MARK L. SPERRY, president of the Scovill Manufacturing Co., Waterbury, Conn., who has been with the company fifty-eight years, has retired. Edward O. Goss, who has been general manager, succeeded Mr. Sperry.

Current Market Reports

The Iron and Steel Market

Pittsburgh, September 24, 1920.

The stagnation in the pig-iron, semi-finished steel and finished steel markets has grown more intense in the past week. The markets for prompt and forward deliveries are equally dull.

For the dullness in the markets for prompt material the much heavier deliveries of late, due to the loosening up in the rail transportation situation, are chiefly responsible. For the dullness in late deliveries, in forward buying, uncertainty as to the future of prices is chiefly responsible.

For four months, April to July inclusive, the steel mills were piling steel, semi-finished and finished, because they could not ship the entire product. At the present time the accumulations are not as much as one-third as heavy as at the maximum, and some observers assert that the stocks are practically all cleaned up. It is clear that the reduction in stocks at mills in the past few weeks has been at two or three or four times as rapid a rate as that by which the stocks were accumulated.

PRICE READJUSTMENTS

It is putting it delicately to say that the lightness of forward buying in pig-iron and steel products is due to uncertainty as to the future of prices. In the mind of the average buyer there seems really to be no uncertainty, but rather a conviction that prices are going to be lower. This does not mean, however, that prices of all steel producers are expected to be lower. There has been a wide range of prices. All the independents have had prices much above those of the Steel Corporation, but some much farther above than others. Nowhere in the trade is the opinion expressed that the Steel Corporation's prices are going to come down. The corporation itself certainly has no such expectation, for after adhering punctiliously to the Industrial Board price schedule of March 21, 1919, for seventeen months, last month the corporation made some slight advances, \$5 per gross ton on wire rods to \$57 and \$5 per net ton on cold-rolled strip steel to 6.15c., while it adopted a new card of nail extras, increasing the cost of an average nail specification 15c. or 20c. a keg.

PRESSURE FOR DELIVERIES

In some lines there is still fairly heavy pressure for deliveries on old contracts, these lines including nails, tin plate, standard steel pipe, oil country goods, the smaller sizes of merchant bars, and sheets. The case of sheets is the most impressive, for the pressure in general exists despite the fact that a large proportion of the sheets due the automobile trade is the subject of suspension of deliveries or of direct cancellation, yet the other consumers want all the sheets that can be furnished.

In plates and structural shapes there is no pressure at all. There are fair deliveries of plates on old contracts. In shapes there is not much contract business on books. The monthly report of the Bridge Builders' and Structural Society shows August bookings of fabricated steel contracts to have represented 40 per cent of the shop fabricating capacity, against 50 per cent for July.

SEMI-FINISHED STEEL SOFTENING

Demand for sheet bars has been light in the past week. On account of light deliveries on old contracts the mills have considerable tonnage due them for fourth quarter and they show little disposition to make fresh contracts. Conversion contracts have been impossible except in isolated cases and thus buying of sheet bars by sheet consumers has largely been absent. Some transactions have occurred, however, and these have been at about \$65 Pittsburgh, or \$2.50 decline. In one or two instances the f.o.b. mill

price was \$62.50 on account of the necessity of equalizing freight with Pittsburgh.

In billets the mill quotation remains at \$60, but this quotation is practically nominal. Attractive lots of billets are offered at second hand at about \$58 Pittsburgh, but there is no demand even for these.

THE CASE OF PIG IRON

Nothing could be clearer than the showing made by pig iron that prices on the recent advance were carried up too far. In most districts pig iron is absolutely stagnant, while in none is there any healthy degree of activity. Deliveries are heavier, as merchant production has increased somewhat, while in addition there has been the movement of furnace stocks previously accumulated, when cars were in short supply. Consumption, on the other hand, shows a decreasing tendency in the case of not a few consumers and none seem to be increasing their melt. These conditions would naturally make for an easier market.

The plainest test, however, is secured by referring to Southern iron. The Birmingham producers were conservative and when their price got up to \$42 Birmingham at the end of last April they did not advance farther. With foundry pig iron on a \$50 level at valley and Cleveland furnaces, Southern iron can penetrate farther, even with the large freight rate advances of Aug. 26, than formerly. Yet the buying of Southern iron is very light, and thus Northern iron at \$50 practically "stands no show."

The Chemical and Allied Industrial Markets

New York, September 24, 1920.

The continued depression in these markets is being attributed to several causes: The unsettled conditions that usually precede a Presidential election, the "waiting" attitude that many consumers have assumed, and a return to more normal and pre-war levels. The depression is felt not in any one particular line, but in all commodity markets, and for this reason tables have been prepared to show the trend.

It will be noticed, among the chemicals, that of the eight items listed four show declines, two have increased and two remain about the same. In the coal-tar bases and intermediates there are six lower prices, one unchanged and two decreases. There have been no increases lately among the naval stores, and prices have been steadily going down. As can be seen, there is a \$5 difference in all grades of rosin between the two years.

The Baltimore Market

Baltimore, Md., September 23, 1920.

Buying activity on this market has not appreciably increased since the last writing. Because of the generally bearish situation, however, parcels of various raw materials are being quietly absorbed by the fertilizer manufacturers at lower prices than nominal quotations. It seems to be the general belief that the materials which have shown the most pronounced decline in prices have about reached the bottom.

Orders for bagged goods are coming in more rapidly and as a consequence the trade is feeling more optimistic than a few weeks ago for a good fall business. The demand, however, for mixed goods will probably show a curtailment, with the result that it will be necessary for some to carry over stocks of raw material until spring.

The local car situation has improved. It is estimated that shippers are now receiving about 75 per cent of their car requirements.

ACID PHOSPHATE

There has been no appreciable weakness in the market for this commodity. Spot parcels are changing hands at prices in line with last quotations of \$20 per ton, bulk acid phosphate, run of pile, basis 16 per cent A. P. A., f.o.b. Baltimore. Also a few sales for export have been noted. Spain has been receiving a fair sized tonnage from this port.

NITRATE OF SODA

The market on nitrate is in a distinctly unsettled condition, with the general trend of the market downward.

Importers are quoting well above the actual market, though there is a report of one recent sale by an importer of a round lot of 95 per cent at \$3.50 ex-vessel Atlantic port for November-December arrival. Spot parcels are being freely offered in the South as low as \$3.50 and counter propositions are being solicited. Deliveries after Jan. 1 are held at higher figures.

SULPHATE OF AMMONIA AND CYANAMIDE

There has been but little change in chemical ammoniates. A few resale parcels of sulphate are being offered at \$5.50 delivered in bulk with counter bids solicited. A sale of a round lot of cyanamide in bags has been reported at \$4.50.

POTASH

The potash market is unchanged. Kainit and manure salts may be had under \$2 and muriate is being quoted nominal at \$2.25. A rise in this market is dependent upon a curtailment of shipments from the German and Alsatian deposits.

FISH SCRAP

Menhaden fish scrap has declined appreciably in price since the last report in this journal. The past week has brought local trading of several thousand tons at prices ranging from \$7.50 per unit of ammonia to \$6.50. This break was due largely to the tight money situation together with lack of storage space at the factories. It is thought that the entire accumulation of scrap on Chesapeake Bay has been cleaned up. It has also been noted that the market has begun to recover as a consequence.

Bromine.....lb.	.70 - .90	1.00 - 1.05
Calcium acetate.....cwt.	3.50 - 3.55
Calcium carbide.....lb.	.04 1/2 - .04 3/4	.04 1/2 - .05 1/2
Calcium chloride, fused, lump.....ton	33.00 - 34.00	35.00 - 45.00
Calcium chloride, granulated.....lb.	.02 - .02 1/2	.03 - .03 1/2
Calcium hypochlorite (bleaching powder).....cwt.	7.25 - 7.50	8.00 - 8.50
Calcium peroxide.....lb.	1.50 - 1.70
Calcium phosphate, monobasic.....lb.75 - .80
Calcium sulphate, pure.....lb.25 - .30
Carbon bisulphide.....lb.	.08 - .09	.10 - .11
Carbon tetrachloride, drums.....lb.	.14 - .15	.16 - .17
Carbonyl chloride (phosgene).....lb.	1.25 - 1.50
Caustic potash (see potassium hydroxide).....
Caustic soda (see sodium hydroxide).....
Chlorine, gas, liquid-cylinders (100 lb).....lb.	.09 - .09 1/2	.10 - .10 1/2
Chloroform.....lb.	.40 - .43	.44 - .47
Cobalt oxide.....lb.	2.00 - 2.05
Copperas (see iron sulphate).....
Copper carbonate, green precipitate.....lb.	.27 - .28	.29 - .31
Copper cyanide.....lb.65 - .70
Copper sulphate, crystals.....lb.	.08 - .09	.09 - .09 1/2
Cream of tartar (see potassium bitartrate).....
Epsom salt (see magnesium sulphate).....
Ethyl Acetate (com. 85%).....gal.	1.10 - 1.30	1.40 -
Ethyl Acetate pure (acetic ether 98% to 100%).....	1.75 -
Formaldehyde, 40 per cent (nominal).....lb.	.48 - .50
Fusel oil, ref.....gal.	5.25 - 6.00
Fusel oil, crude (nominal).....gal.
Glauber's salt (see sodium sulphate).....
Glycerine, C. P. drums extra.....lb.26 1/2 - .28 1/2
Iodine, resublimed.....lb.	4.30 - 4.35	4.40 - 4.45
Iron oxide, red.....lb.03 - .20
Iron sulphate (copperas).....cwt.	2.00 - 2.25	2.35 - 2.75
Lead acetate, normal.....lb.13 - .16
Lead arsenate (paste).....lb.	.11 - .12	.13 - .17
Lead nitrate, crystals.....lb.90 - 1.00
Litharge.....lb.	.14 - .15	.15 1/2 - .16
Lithium carbonate.....lb.	1.50 -
Magnesium carbonate, technical.....lb.	.12 1/2 - .13 1/2	.15 - .16
Magnesium sulphate, U. S. P.....100 lb.	3.50 - 3.90	4.00 - 4.50
Magnesium sulphate, commercial.....100 lb.	3.50 - 3.60
Methanol, 95%.....gal.	3.25 - 3.30
Methanol, pure.....gal.	3.50 - 4.50
Nickel salt, double.....lb.14 - .16
Nickel salt, single.....lb.13 - .14
Phosgene (see carbonyl chloride).....
Phosphorus, red.....lb.	.50 - .55	.60 - .65
Phosphorus, yellow.....lb.35 - .37
Potassium bichromate.....lb.	.34 - .36	.39 - .40

	Carlota	Less Carlota
Potassium bitartrate (cream of Tartar) . . . lb.	\$0.52 - \$0.56	\$0.57 - \$0.58
Potassium bromide, granular . . . lb.	—	.73
Potassium carbonate, U. S. P. . . lb.	.50 - .55	.60
Potassium carbonate, crude . . . lb.	.20 - .21	.25
Potassium chlorate, crystals . . . lb.	.18 - .18 1/2	.19 - .20
Potassium hydroxide (caustic potash) . . lb.	.27 - .28	.29 - .33
Potassium iodide . . . lb.	—	3.35 - 3.60
Potassium nitrate . . . lb.	.17 - .17 1/2	.19 - .21
Potassium permanganate . . . lb.	.75 - .80	.85 - .95
Potassium prussiate, red . . . lb.	.85 - .95	1.00 - 1.05
Potassium prussiate, yellow . . . lb.	.32 - .36	.35 - .40
Potassium sulphate (powdered) . . . ton	\$240.00 - 255.00	—
Rochelle salts (see sodium potas. tartrate)	—	—
Sal ammoniac (see ammonium chloride)	—	—
Salt soda (see sodium carbonate)	—	—
Salt cake . . . ton	—	48.00 - 50.00
Silver cyanide (nominal) . . . os.	—	1.25 - .62
Silver nitrate (nominal) . . . os.	—	.60 - .62
Soda ash, light . . . 100 lb.	—	2.80 - 3.00
Soda ash, dense . . . 100 lb.	—	3.25 - 3.50
Sodium acetate . . . lb.	10 - 15	.20 - .25
Sodium bicarbonate . . . 100 lb.	2.50 - 2.75	3.00 - 3.50
Sodium bichromate . . . lb.	.22 - .24	.26 - .27
Sodium bisulphate (nitre cake) . . . ton	7.00 - 8.00	9.00 - 11.00
Sodium bisulphate Powdered, U. S. P. . lb.	.08 1/2 - .10	.10 - .11
Sodium borate (borax) . . . lb.	.09 - .10	.11 - .12
Sodium carbonate (sua soda) . . . 100 lb.	2.00 - 2.10	2.15 - 2.25
Sodium chlorate . . . lb.	.11 - .12	.12 1/2 - .14
Sodium cyanide, 96-98 per cent . . . lb.	.25 - .30	.32 - .35
Sodium fluoride . . . lb.	.18 - .19	.19 - .20
Sodium hydroxide (caustic soda) . . . 100 lb.	5.60 - 5.70	5.75 - 6.00
Sodium hyposulphite . . . lb.	—	.03 - .04
Sodium metabisulphite . . . lb.	2.50 - 3.00	3.25 - 3.75
Sodium nitrate . . . 100 lb.	3.00 - 3.25	3.75 - 4.00
Sodium nitrite . . . lb.	.16 - .18	.19 - .20
Sodium peroxide, powdered . . . lb.	.32 - .35	.35 - .40
Sodium phosphate, dibasic . . . lb.	.03 1/2 - .04 1/2	.04 - .05
Sodium potassium tartrate (Rochelle salts) lb.	—	.39 - .40
Sodium prussiate, yellow . . . lb.	.25 - .27	.31 - .32
Sodium silicate, solution (40 deg) . . . lb.	.01 1/2 - .01 3/4	.02 - .02 1/2
Sodium silicate, solution (60 deg) . . . lb.	.02 1/2 - .03	.04 - .05
Sodium sulphate, crystals (Glauber's salt) cwt	1.60 - 1.70	1.75 - 2.50
Sodium sulphide, crystal, 60-62 percent (cone) lb.	.09 - .10	.10 - .11
Sodium sulphite, crystals . . . lb.	.04 - 0.45	.04 - .05
Strontium nitrate, powdered . . . lb.	.15 - .18	.19 - .20
Sulphur chloride, red . . . lb.	.08 - .09	.10 - .10 1/2
Sulphur, crude . . . ton	16.00 - 20.00	—
Sulphur dioxide, liquid, cylinders . . . lb.	.09 - .10	.12 - .13
Sulphur (sublimed), flour . . . 100 lb.	—	3.80 - 4.35
Sulphur, roll (brimstone) . . . 100 lb.	—	3.40 - 3.90
Tin bichloride (stannous) . . . lb.	.42 1/2 - .44	.45 - .46
Tin oxide . . . lb.	—	.55 - .65
Zinc carbonate, precipitate . . . lb.	.16 - .18	.19 - .20
Zinc chloride, gran. . . lb.	.13 - .13 1/2	.13 - .17
Zinc cyanide . . . lb.	.45 - .49	.50 - .60
Zinc dust . . . lb.	.12 - .13	.13 - .14
Zinc oxide, U. S. P. . . lb.	.17 - .25	.25 - .30
Zinc sulphate . . . lb.	.03 1/2 - .03 3/4	.04 - .06

Coal-Tar Products

NOTE: The following prices are for original packages in large quantities:

Alpha naphthol, crude . . . lb.	\$1.30	\$1.40
Alpha naphthol, refined . . . lb.	1.50	1.65
Alpha-naphthylamine . . . lb.	.48	.52
Aniline oil, drums extra . . . lb.	.30	.33
Aniline salts . . . lb.	.55	.40
Aniline, 80%, in drums (100 lb) . . . lb.	.90	1.00
Benzaldehyde (C ₆ H ₅ CHO) . . . lb.	2.00 - 2.10	2.10
Benzidine, base . . . lb.	1.35	1.40
Benzidine sulphate . . . lb.	1.15	1.25
Benzoin acid, U. S. P. . . lb.	.85	.90
Benzoin of soda, U. S. P. . . lb.	.80	.90
Benzene, pure, water-white, in drums (100 gal) . gal	.35 - .40	.40
Benzene, 90%, in drums (100 gal) . gal	.33 - .38	.38
Benzyl chloride, 95-97%, refined . . . lb.	.35 - .40	.40
Benzyl chloride, tech . . . lb.	.25	.35
Beta-naphthol benzoin (nominal) . . . lb.	1.50	4.00
Beta-naphthol, sublimed (nominal) . . . lb.	.70 - .75	.75
Beta-naphthol, tech (nominal) . . . lb.	.65 - .70	.70
Beta-naphthylamine, sublimed . . . lb.	2.25 - 2.40	2.40
Cresol, U. S. P., in drums (100 lb) . . lb.	.18 - .19	.19
Ortho-cresol, in drums (100 lb) . . . lb.	.23 - .25	.25
Cresylic acid, 97-99%, straw color, in drums . gal	1.10	1.10
Cresylic acid, 95-97%, dark, in drums . . gal	1.05	1.10
Cresylic acid, 50%, first quality, drums . . gal	.65 - .75	.75
Dichlorobenzene . . . lb.	.07 - .10	.10
Diethylaniline . . . lb.	1.50	1.60
Dimethylaniline . . . lb.	.20 - .25	.25
Dinitrobenzene . . . lb.	.30 - .35	.35
Dinitrochlorobenzene . . . lb.	.32 - .35	.35
Dinitronaphthalene . . . lb.	.45 - .55	.55
Dinitrophenol . . . lb.	.40 - .45	.45
Dinitrotoluene . . . lb.	.40 - .45	.45
Dip oil, 25%, tar acids, cat lots, in drums . gal	.38 - .40	.40
Diphenylamine (nominal) . . . lb.	.80 - .85	.85
Fluoride (nominal) . . . lb.	1.90 - 2.05	2.05
Meta-phenylenediamine . . . lb.	1.25 - 1.30	1.30
Monochlorobenzene . . . lb.	.18 - .20	.20
Monochethylaniline . . . lb.	2.00 - 2.40	2.40
Naphthalene crushed, in bbls. (250 lb.) . . lb.	—	.17
Naphthalene, flake . . . lb.	.16 - .17	.17
Naphthalene, balls . . . lb.	.16 - .17	.17
Naphthionic acid, crude . . . lb.	.75 - .85	.85
Nitrobenzene . . . lb.	.14 - .19	.19
Nitro-naphthalene . . . lb.	.40 - .50	.50
Nitro-toluene . . . lb.	.18 - .25	.25
Ortho-amidophenol . . . lb.	3.25 - 4.25	4.25
Ortho-dichlorobenzene . . . lb.	.15 - .20	.20
Ortho-nitro-phenol . . . lb.	.80 - .85	.85
Ortho-nitro-toluene . . . lb.	.25 - .40	.40
Ortho-toluidine . . . lb.	.35 - .38	.38
Para-amidophenol, base . . . lb.	2.50 - 3.00	3.00
Para-amidophenol, HCl . . . lb.	2.50 - 3.00	3.00
Para-dichlorobenzene . . . lb.	.08 - .12	.12
Paranitroaniline . . . lb.	1.10 - 1.15	1.15

Para-nitrotoluene . . . lb.	1.25 - 1.40
Para-phenylenediamine . . . lb.	2.50 - 2.65
Para-toluidine . . . lb.	2.00 - 2.25
Phthalic anhydride . . . lb.	.70 - .75
Phenol, U. S. P., drums (dest.), (240 lb.) . . lb.	.12 - .20
Pyridine . . . gal	2.00 - 3.50
Resorcinol, technical . . . lb.	4.25 - 4.50
Resorcinol, pure . . . lb.	6.25 - 6.75
Salicylic acid, tech, in bbls. (110 lb) . . . lb.	.45 - .50
Salicylic acid, U. S. P. . . lb.	.45 - .50
Salol . . . lb.	.90 - 1.00
Solvent naphtha, water-white, in drums, 100 gal. gal	.40 - .35
Solvent naphtha, crude, heavy, in drums, 100 gal. gal	.20 - .26
Sulphanilic acid, crude . . . lb.	.32 - .35
Tolidine . . . lb.	1.70 - 2.50
Toluidine, mixed . . . lb.	.45 - .55
Toluene, in tank cars . . . gal	.35 - .40
Toluene, in drums . . . gal	.38 - .40
Xylidines, drums, 100 gal. . . lb.	.50 - .65
Xylene, pure, in drums . . . gal	.47 - .50
Xylene, pure, in tank cars . . . gal	.45 - .50
Xylene, commercial, in drums, 100 gal . . . gal	.32 - .35
Xylene, commercial, in tank cars . . . gal	.30 - .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark . . . lb.	\$0.36 - \$0.39
Beeswax, refined, light . . . lb.	.37 - .38
Beeswax, white pure . . . lb.	.65 - .68
Carnauba, No. 1, (nominal) . . . lb.	.90 - .95
Carnauba, No. 2, regular (nominal) . . . lb.	.85 - .86
Carnauba, No. 3, North Country . . . lb.	.35 - .36
Japan . . . lb.	.17 - .18
Montan, crude . . . lb.	.25 - .26
Paraffine waxes, crude match wax (white) 105-110 m p . . . lb.	.09 - .09 1/2
Paraffine waxes, crude, wende 124-126 m p . . . lb.	.09 - .10
Paraffine waxes, refined, 118-120 m p . . . lb.	.11 - .11 1/2
Paraffine waxes, refined, 125 m p . . . lb.	.12 - .13
Paraffine waxes, refined, 128-140 m p . . . lb.	.13 - .15
Paraffine waxes, refined, 133-135 m p . . . lb.	.16 - .17
Paraffine waxes, refined, 145-157 m p . . . lb.	.17 - .18
Stearic acid, single pressed . . . lb.	.20 - .21
Stearic acid, double pressed . . . lb.	.22 - .23
Stearic acid, triple pressed . . . lb.	.24 - .25

NOTE: Paraffine waxes very scarce

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on earload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist. sp. gr. 0.930-0.940 . . . gal.	\$2.15
Pine oil, pure, dest. dist. . . gal	1.80
Pine tar oil, ref. sp. gr. 1.025-1.035 . . . gal	.48
Pine tar oil, crude sp. gr. 1.025-1.035 (tankers) f.o.b. Jacksonville, Fla. gal	.35
Pine tar oil, double ref. sp. gr. 0.965-0.990 . . . gal	.85
Pine tar, ref. thin, sp. gr. 1.080-1.060 . . . gal	.36
Turpentine, crude, sp. gr. 0.900-0.970 . . . gal	1.75
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990 . . . gal	.35
Pine wood creosote, ref. . . gal	.52

Naval Stores

The following prices are f.o.b. New York, for earload lots

Rosin B. D. bbl . . . 280 lb.	\$13.00
Rosin E. L. . . . 280 lb.	13.10
Rosin K-N . . . 280 lb.	13.15
Rosin W. G-W-W . . . 280 lb.	13.25
Wood rosin, bbl . . . 280 lb.	12.50
Spirits of turpentine . . . gal	1.45
Wood turpentine, steam dist. . . gal	—
Wood turpentine, dest. dist. . . gal	—
Pine tar patch, bbl . . . 200 lb.	8.50
Tar, kiln burned, bbl (500 lb) . . . bbl	4.50 - 15.00
Retort tar, bbl . . . 500 lb.	5.00 - 15.00
Rosin oil, first run . . . gal	.72
Rosin oil, second run . . . gal	.55
Rosin oil, third run . . . gal	.92

Solvents

73-76 deg., steel bbls. (85 lb) . . . gal	\$0.40
70-72 deg., steel bbls. (85 lb) . . . gal	.38
68-70 deg., steel bbls. (85 lb) . . . gal	.37
V. M. and P. naphtha, steel bbls. (85 lb) . . . gal	.29

Crude Rubber

Para - Upriver fine . . . lb.	\$0.27 - \$0.28
Upriver coarse . . . lb.	.18 - .19
Upriver cauchó ball . . . lb.	.18 - .19
Plantation - First latex crop . . . lb.	.25 - .26
Highland smoked sheets . . . lb.	.23 - .24
Brown crepe, thin, clean . . . lb.	.22 - .23
Amber crepe No. 1 . . . lb.	.22 - .23

Oils

VEGETABLE

The following prices are f.o.b. New York for earload lots.

Castor oil, No. 3, in bbls . . . lb.	\$0.16 - \$0.18
Castor oil, AA, in bbls . . . lb.	.17 - .17 1/2
China wood oil, in bbls. (f.o.b. Pac. coast) . . lb.	.17 - .18
Cocanut oil, Ceylon grade, in bbls . . . lb.	.15 - .16
Cocanut oil, Ceylon grade, in bbls (nominal) . lb.	.16 - .17
Corn oil, crude, in bbls . . . lb.	.10 - .11
Cottonseed oil, crude (f.o.b. mill) . . . lb.	.14 - .15
Cottonseed oil, summer yellow . . . lb.	.14 - .15
Cottonseed oil, winter yellow . . . lb.	.14 - .15
Lined oil, raw, ear lots (domestic) . . . gal	1.22 - 1.25
Lined oil, raw, tank cars (domestic) . . . gal	1.16 - 1.20
Lined oil, boiled, ear lots (domestic) . . . gal	1.24 - 1.28

Olive oil, commercial.....	gal.	3.00	—	3 50
Palm, Lagos.....	lb.	.103	—	—
Palm, bright red.....	lb.	—	—	—
Palm, Niger.....	lb.	.091	—	.10
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.101	—	.121
Peanut oil, refined, in bbls.....	lb.	.17	—	.18
Rapeseed oil, refined in bbls.....	gal.	1.30	—	1.45
Rapeseed oil, blown, in bbls.....	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.14	—	.141
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.10	—	.11

FISH

Winter pressed Menhaden.....	gal.	\$0.85	—	\$0 90
Yellow bleached Menhaden.....	gal.	.87	—	.90
White bleached Menhaden.....	gal.	.90	—	.92
Blown Menhaden.....	gal.	1.05	—	—

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$22 00	—	\$25 00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	18 00	—	20 00
Barytes, crude, 88% to 94% ba., Kings Creek.....	net ton	8 00	—	10 00
Barytes, ground, white, f.o.b. Cartersville, Ga.....	net ton	23 00	—	25 00
Barytes, ground, off color, f.o.b. Cartersville.....	net ton	16 00	—	19 00
Barytes, crude, 88% to 94% ba., Cartersville.....	net ton	12 00	—	—
Barytes, floated, f.o.b. St. Louis.....	net ton	26 50	—	28 00
Barytes, crude, min. 98% ba., Missouri.....	net ton	11 00	—	11 25
Blanc fixe, dry.....	lb.	.05	—	.06
Blanc fixe, pulp.....	net ton	60 00	—	60 00
Casoon.....	lb.	.15	—	.18
Chalk, domestic, extra light.....	lb.	.05	—	.06
Chalk, domestic, light.....	lb.	.04	—	.05
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04	—	.05
China clay, (kaolin) crude, f.o.b. mines, Georgia.....	net ton	9 00	—	12 00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12 00	—	15 00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18 00	—	22 00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8 00	—	12 00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15 00	—	40 00
China clay (kaolin), imported, lump.....	net ton	25 00	—	35 00
China clay (kaolin), imported, powdered.....	net ton	30 00	—	60 00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	7 50	—	8 00
Feldspar, crude, f.o.b. Maine.....	net ton	7 50	—	10 00
Feldspar, ground, f.o.b. Maine.....	net ton	21 00	—	23 00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17 00	—	21 00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17 00	—	21 00
Feldspar, ground, f.o.b. Baltimore.....	net ton	30 00	—	35 00
Fuller's earth, granular, f.o.b. Fla.....	net ton	25 00	—	—
Fuller's earth, powdered, f.o.b. Fla.....	net ton	18 00	—	—
Fuller's earth, imported, powdered.....	net ton	35 00	—	40 00
Graphite (dust) polish grade 50% Ashland, Mo.....	lb.	—	—	.01
Graphite (dust) facing grade 50% Ashland, Mo.....	lb.	—	—	.02
Graphite, crucible, 80% carbon Ashland, Mo.....	lb.	—	—	.05
Graphite, crucible, 90% carbon Ashland, Mo.....	lb.	—	—	.10
Graphite, crucible, 85% carbon.....	lb.	—	—	.08
Graphite, crucible, 88% carbon.....	lb.	—	—	.09
Graphite, crucible, 90% carbon.....	lb.	—	—	.10
Magnesite, imported, lump.....	lb.	.04	—	.05
Pumice stone, domestic, lump.....	lb.	.06	—	.07
Pumice stone, ground.....	lb.	.04	—	.07
Quartz (acid tower) set to head, f.o.b. Baltimore.....	net ton	—	—	10 00
Quartz (acid tower) 1/2 to 2 in., f.o.b. Baltimore.....	net ton	—	—	14 00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

SAN FRANCISCO—The Federal Rubber Co., Cudahy, Wis., will soon award the contract for the construction of a 5-story factory for the manufacture of tires, etc. Estimated cost, \$150,000. G. B. Allen, archt. and engr.

Connecticut

NAUGATUCK—The Rubber Regenerating Co., Elm St., has awarded the contract for the construction of a 1-story addition to machine shop and alterations to other buildings at plant to the F. T. Ley Co., Inc., 499 Main St., Springfield, Mass. Estimated cost, \$50,000.

NEW HAVEN—The Nustone Products Corp., Waterfront St., will build a 1-story, 95x100-ft. stone products factory. Estimated cost, \$12,000. Work will be done by day labor.

UNION CITY (Naugatuck P. O.)—The Eastern Malleable Iron Co. has awarded the contract for altering and building additions to the present plant to the Fred T. Ley Co., Inc., 499 Main St., Springfield, Mass. Estimated cost, \$50,000.

VERSAILLES—The Versailles Sanitary Fibre Mills has awarded the contract for the construction of a paper factory to the H. Wales Lines Co., 134 State St., Meriden. Estimated cost, \$100,000.

Delaware

WILMINGTON—The Wilmington Sugar Refining Co. plans to build a sugar refinery. Estimated cost, \$2,000,000. W. Higginson, 18 East 41st St., New York City, archt. and engr.

Illinois

CHICAGO—The Coca-Cola Co. plans to build a plant on Crawford and Karlov Aves. Estimated cost, \$750,000.

CHICAGO—The Sherwin-Williams Co., 116th St. and Stephenson Ave., is building a white lead manufacturing plant and is in the market for equipment for the manufacture of litharge and red lead.

Kansas

CHIANUTE—The Mutual Oil Co., Mutual Bldg., Kansas City, Mo., will build a 3-story, 35x90-ft. wax plant for the manufacture of lubricating oil. Estimated cost, \$100,000. Work will be done by day labor.

TOPEKA—The Topeka Fdry. & Iron Co., 318-322 Jackson Ave., plans to construct 3 buildings, including a foundry and machine shop. Estimated cost, \$100,000.

Maine

WATERVILLE—The Keyes Fibre Co. has awarded the contract for the construction of a paper factory to the Aberthaw Constr. Co., 27 School St., Boston. Estimated cost, \$100,000. Webster & Leroy, 534 Congress St., Portland, engr.

Maryland

BALTIMORE—The Bd. of Awards has awarded the contract for the construction of a hydrolytic tank, sludge digestion tank, etc., at the sewage disposal works, west shore Back River, to the Robertson Bros., 106 Hopkins Pl.

BALTIMORE—The Interocean Oil Co., East Lexington St., plans to build a 1-story, 80x38-ft. chemical laboratory. Estimated cost, \$7,788. O. F. Adams, archt.

BALTIMORE—The Whitaker Paper Co., 415 Guilford Ave., has awarded the contract for the construction of an 8-story, 100x186-ft. warehouse on Guilford Ave., Saratoga and Davis Sts. to the Turner Constr. Co., 344 Madison Ave., New York City. Estimated cost, \$600,000.

Massachusetts

EAST PEPPERELL—The Nashua River Paper Co. plans to build a paper factory addition. Estimated cost, \$100,000.

HOLYOKE—The Perfect Safety Paper Co., Winter St., plans to build a 60x100-ft. paper factory addition on Appleton and Winter Sts. Estimated cost, from \$75,000 to \$100,000. Howes & Howes, 243 High St., archts.

Michigan

MARYSVILLE—The Aluminum Castings Co., c/o E. E. Allyne, 2800 Harvard Ave., Cleveland, O., plans to build a 2-story factory. Estimated cost, \$75,000.

ONTONAGON—The Northern Fibre Co. has awarded the contract for the construction of a 2-story pulp mill to W. E. Ule, Stevens Point, Wis. Estimated cost, \$350,000.

OWOSSO—The city has awarded the contract for furnishing labor and material for the construction of a water filtration plant with 1,000,000 gal. capacity to the Ann Arbor Asphalt Constr. Co., Ann Arbor. Estimated cost, \$75,000.

Minnesota

WABASSO—The city rejected all bids for the construction of a sewage treatment plant and general sewer. Estimated cost, \$15,000. J. F. Druar, 512 Globe Bldg., St. Paul, engr. Noted Sept. 1.

Missouri

EXCELSIOR SPRINGS—The city plans an election Oct. 4 to vote on \$25,000 bonds to construct a disposal plant, etc. Shockey Eng. Co., Kansas City, engr.

MOBERLY—The city is having plans prepared for the construction of an impounding dam, filter plant, etc. Estimated cost, \$350,000. Fuller & Beard, Chemical Bldg., St. Louis, engr. Noted July 14.

SPRINGFIELD—The Wood Everett Stove Co. plans to build a 2-story foundry. Estimated cost, \$100,000.

WEBB CITY—The Rock Paint & Cloth Co. is having plans prepared for the construction of a 2-story, 61x150-ft. paint factory. Estimated cost, \$150,000. Bucy Miller Eng. Co., Joplin, engr.

Nebraska

CHAPPEL—The city plans to build a sewage disposal plant and sewer system. Sewage treatment and Imhoff tank and sand filters will be installed in same. Estimated cost, \$90,000. Hensingson Eng. Co., 12th and Harney Sts., Omaha, engr.

North Dakota

HURDSFIELD—The Bd. Educ. will soon award the contract for the construction of a 2-story, 68x89-ft. grade and high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. R. H. Corson, clk. W. D. Gillespie, Fargo, archt.

Ohio

AKRON—The Miller Rubber Co., South High St., will build a 3-story, 60x210-ft. factory. Estimated cost, \$100,000. Work will be done by day labor.

CLEVELAND—The Bd. Educ. will receive bids until October 1 for the construction of a 1-story sewage treatment and water pumping plant. Estimated cost, \$50,000. C. W. Bates, Natl. Bank Bldg., Wheeling, W. Va., archt.

CLEVELAND—The Peerless Motor Car Co., East 93rd St. and Quincy Ave., rejected bids for the construction of a 1-story, 60x100-ft. japanning building. Estimated cost, \$100,000. Carter, Richards, Griffith Co., Illuminating Bldg., archts and engr.

COLUMBUS—The city will receive bids until Oct. 4 for the construction of additions and repairs to the sewage disposal plant on Dawson Ave. P. N. Roderick, village clk.

TOLEDO—The Maumee Tire & Rubber Co., 705 Madison Ave., is having plans prepared for the construction of a 3-story, 100x300-ft. rubber tire factory on Lackey Rd. Estimated cost, \$300,000. G. G. Morrison, pres. Osborn Eng. Co., 2848 Prospect Ave., archt. and engr.

Oklahoma

DOUGHERTY—The Continental Asphalt & Refining Co., Oklahoma City, will build a refinery here. Estimated cost, \$1,000,000. Work will be done by day labor.

OKLAHOMA CITY—The city will soon receive bids for the construction of a sewage disposal plant. Estimated cost, \$1,000,000. Pierce, Greeley & Hansen, 39 West Adams St., Chicago, Ill., engr. Noted July 14.

SPIRO—The city plans an election Nov. 4 to vote on \$50,000 bonds to construct a sewage disposal plant, etc.

Pennsylvania

PHILADELPHIA—E. Hubschman, Orleana and Willow Sts., has awarded the contract for the construction of a 1-story, 60x90-ft. leather factory addition, to Monaghan & Lossie, 3016 Chestnut St.

PHILADELPHIA—McIlvain Bros., 15th and Hamilton Sts., will soon award the contract for altering their drug factory. Ballinger & Perrot, 329 South Broad St., archts.

Rhode Island

PROVIDENCE—Brown University, Prospect St., will soon award the contract for the construction of a 3-story, 50x200-ft. laboratory. Estimated cost, \$250,000. Day & Klaunder, 925 Chestnut St., Philadelphia, Pa., archts. and engr. Noted Aug. 25.

Texas

WICHITA FALLS—The State Bd. of Control, Austin, will receive bids until Oct. 4 for the construction of a sewage disposal plant, etc., at the Northwest Texas Insane Asylum, here. C. H. Page & Bros., Austin Natl. Bank Bldg., Austin, archts.

Wisconsin

BELGIUM—The city had plans prepared for the installation of septic tank, etc. Estimated cost, \$25,000. J. Donohue, 8th St., Sheboygan, engr.

HARTFORD—The city is having plans prepared for the installation of sewage disposal tanks, etc. Estimated cost, \$25,000. C. Lehn, West Bend, engr.

MILWAUKEE—The Natl. Brake & Electric Co., Bellevue Pl., has awarded the contract for the construction of a 1-story, 164x180-ft. foundry addition to Paul Riessen's Sons, 1009 Humboldt Ave. Estimated cost, \$250,000. Noted April 21.

OSHKOSH—The Mercy Hospital, 185 Hazel St., is having plans prepared for the construction of a 4-story hospital addition and nurses' home on Hazel St. Chemical laboratories will be installed in same. Estimated cost, \$600,000. E. Brielmoeller & Sons, University Bldg., Milwaukee, archts and engr.

SHEBOYGAN—The Columbia Rubber Mills, 176 16th St., Milwaukee, has awarded the contract for the construction of a 2-story, 100x170-ft. factory to Herman Loesing, 914 Superior St. Estimated cost, \$60,000. Noted Aug. 11.

SHEBOYGAN—The Tomah Rubber Co., 176 16th St., Milwaukee, has awarded the contract for the construction of a 2-story, 70x100-ft. rubber factory on Lyman Ave. to H. Loesing, 914 Superior St. Estimated cost, from \$50,000 to \$60,000. Noted Aug. 4.

Ontario

LONDON—The Daughters of the Empire has awarded the contract for the construction of a 3-story, 100x280-ft. children's hospital on Ottawa Ave., to John Fotherbough, 272 Regent St. Special laboratory equipment will be installed in same. Estimated cost, \$250,000.

OTTAWA—The Ottawa Paint Works, 687 Wellington St., has awarded the contract for altering paint factory on Wellington St. to A. Christie & Son, Kensington Apts., Elgin St. Estimated cost, \$50,000.

SANDWICH EAST—The city plans an election to vote on \$200,000 bonds to construct intercepting sewers, sewage disposal plant, etc. Morris Knowles, Ltd., Heintzman Bldg., Windsor, engr.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN ENGINEERING COUNCIL, of the Federated American Engineering Societies will hold a meeting Nov. 18 and 19, 1920, in Washington, D. C. Headquarters will be at the New Willard Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1920 convention and exhibit at Columbus, Ohio, the week of Oct. 4.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1920 annual meeting will be held in the Engineering Societies' Building, from Dec. 7 to 10 inclusive.

CANADIAN INSTITUTE OF MINING AND METALLURGY will hold its second annual Western meeting in Winnipeg, Man., on Oct. 25, 26 and 27. Headquarters will be at the Hotel Fort Garry.

ELECTRIC FURNACE ASSOCIATION will hold a meeting Oct. 6, at Columbus, Ohio, the subject of which will be "Refractories."

ENGINEERING COUNCIL will hold its next meeting in Chicago, Thursday, Oct. 21.

INSTITUTE OF METALS DIVISION OF THE A. I. M. E. will hold its annual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 1.

NATIONAL ASSOCIATION OF PURCHASING AGENTS will hold its annual convention at the Congress Hotel, Chicago, Ill., Oct. 11, 12 and 13.

THE RUBBER SECTION of the National Safety Council will consider safety problems of especial interest to the rubber industry at a section conference to be held Sept. 29 to Oct. 1, in connection with the national session of the Council to be held in Chicago.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12.

Industrial Notes

W. S. ROCKWELL CO., New York, calls attention to Bull. 217, dated June, 1920, on "Automatic and Semi-Automatic Furnaces for the Continuous Heat-Treatment of Metals." This bulletin is a review of methods and equipment that the company has developed in recent years and which have shown their value in practice.

WELLS MFG. CO., Chicago, Ill., is issuing a four-page folder on coal handling equipment which helps solve the labor problem.

EGGERS WITTEZ, Brooklyn, N. Y., designer and builder for the enamel, glass, iron and steel industries of patent recuperator system furnaces, has issued a booklet giving illustrations and descriptions of different furnaces, together with illustrations of actual installations.

ROSS-TACONY CRUCIBLE CO., Philadelphia, Pa., has issued an illustrated booklet on its crucibles, phosphorizers, retorts, stirrers, skimmers, etc., special crucibles, stoppers, nozzles and sleeves.

WESTON DODSON & CO., INC., announces the appointment as export sales manager, of E. R. Wadleigh, formerly consulting and export engineer, vice J. H. Davidson, resigned, and of J. W. Sands as assistant export sales manager.

W. M. HUMPHREY has purchased the plant of the Gas Oil Chemical Co. of Hammond, Ind., and will enter immediately into the manufacture of dye intermediates, including paratoluidine, orthotoluidine and paranitrotoluidine.

THE KEWAUNEE MFG. CO., Kewaunee, Wis., has elected C. G. Campbell a member of the board of directors and has appointed him general manager.

THE POWERS REGULATING CO. has recently moved into a large modern fire-proof factory building having floor space of about 40,000 sq. ft. The company has grown to this size from the small beginnings in 1890 when W. P. Powers turned out the first house regulators in a small room 12 x 16 ft. Recently the older employees of the company, including one who has been with the organization from the beginning, presented W. P. Powers, their president, with a silver cup in token of their affection and esteem.

THE SIMONDS MFG. CO. has just completed an addition 40 x 50 to its research laboratory connected with its steel mills at Lockport, N. Y. Additional equipment consisting of a 300 to 500 lb. capacity special type electric melting furnace, several electric heating furnaces and other tools and equipment have been installed, with a view of greatly extending facilities for carrying on development and research work. New formulas and methods for making special steels will be worked out at the enlarged laboratory under the direction of an expert metallurgical staff.

THE WESTINGHOUSE ELECTRIC & MFG. CO.'s war memorial scholarship committee has announced as the winners of the four scholarships for the coming year, 1920-21, Alva C. Corrao, small motor drafting department; Henry Gardiner Symonds, son of N. G. Symonds, manager industrial sales division, Chicago office; J. Dale Seabert, transformer engineering department, and Herbert R. Hillman, son of William A. Hillman, who has been a machinist in the works of the R. D. Nuttall Co. for twenty-seven years. These memorial scholarships were established in 1919 as a means for perpetuating the memory of those employees of the Westinghouse company and its subsidiary companies who took part in the great war. Each scholarship carries with it the annual payment of \$500 for a period not to exceed four years. The payment is to be applied towards an engineering education in any technical school or college selected by the successful candidate. Scholarships are granted for one year only, and approved by the scholarship committee, but are continued for the full course provided the scholar maintains the academic and other standards required by the institution. The awarding of the scholarships is based upon the personal character of the applicants and grades in examinations.

AMOR A. HANKS, who has long conducted an assay office and chemical laboratory at 630 Sacramento St., San Francisco, and testing laboratories in separate quarters, has recently moved into a new and larger building at 621 Sacramento St. The new building will house the entire laboratory equipment and contains a sampling room, an assay room, a chemical laboratory with dark room, a testing laboratory and a library. The more commodious quarters permit of the efficient arrangement of equipment and allow space for additional apparatus. The testing laboratory is thoroughly equipped to handle materials of construction and commerce. There is a growing demand for this class of work both in volume and variety due to the increase in foreign trade through the port of San Francisco as well as because of the evident need of inspection of incoming and outgoing shipments. The testing laboratory has an experienced personnel and is in position to perform efficient service.

CHARLES WHITING BAKER, for many years editor-in-chief of *Engineering News* and since 1917 consulting editor of *Engineering News-Record*, announces his resignation and the establishment, under his direction, of the Engineering Business Exchange, with offices at 30 Church St., New York City, an agency to bring together those desiring to sell any sound engineering or technical business manufacturing, constructing, selling or professional—and those seeking opportunities to purchase.

THE AJAX ELECTROTHERMIC CORP., Trenton, N. J., announces that Dr. E. F. Northrup has recently been elected vice-president of the company and is now engaged in perfecting the brass-melting furnace of the Ajax-Northrup type. Dr. Northrup has resigned his professorship at Princeton University in order to devote his entire time to the business of the company.

Manufacturers' Catalogs

THE PENNSYLVANIA FORGE CO., Bridgeburg, Philadelphia, Pa., has issued a 32-page booklet on Forges and Pressed Steel Die Blocks Made from Acid O.H. Steel. This booklet is known as Cat. No. 3.

THE MONARCH MFG. WORKS, INC., Philadelphia, Pa., has issued a 4-page folder, Cat. 6, Section C, on improved chemical sprays, which gives descriptive matter and illustrations.

THE WARREN CHEMICAL DIVISION of The Barrett Co., New York, calls attention to a small booklet on Alkali and Acid-Proof Anchor Rock Asphalt Floors.

THE MINE & SMELTER SUPPLY CO., New York City, has just received from the press Bull. No. 63, on Massco Furnaces for melting, hardening, tempering, annealing, forging, assay work, ore roasting, etc., using oil, gas or gasoline fuel. This attractive 48-page booklet gives illustrations and descriptive matter of the following furnaces: crucible tilting; potless tilting; small stationary gas; gasoline melting; muffle; rod heating; pack hardening; billet forge; annealing; oil forge; die hardening; reverberatory and mechanical roasting, together with burners, accessories and motor blowers.

MOJONNIER BROS. Co., engineer, Chicago, has just issued a new 160-page catalog on Scientific Dairy Apparatus and Supplies, wherein is shown a comprehensive line of the company's own apparatus, also a very complete line of laboratory accessories for the chemical and bacteriological control of milk and milk products. The second section of the catalog is devoted to vacuum pans, sterilizers, pumps and a complete line of heavy machinery used in condensed and evaporated milk plants.

LEEDS & NORTHRUP CO., Philadelphia, Pa., has issued Cat. No. 75, entitled "Electrometric Methods and Apparatus for Determining Hydrogen Ion Concentrations." This booklet contains the following: General Considerations, The Working Formulas, Electrometric Methods Applicable to Hydrogen Ion Measurements, Methods Employing Potentiometer Principle, Practical Considerations in Applying Working Formulas, Applications of the Gas Chain to Titration Analysis, Industrial Applications of Gas Chain Methods, Bibliography and Price List.

THE YARNALL-WARING CO., Philadelphia, Pa., is distributing Bull. No. 410, descriptive of the Yarrow scotch and double tightening blow off valves, both separately and in combination. The Yarrow double tightening valve is a new development, having been designed primarily to use in conjunction with the scotch valves in certain states where boiler laws require use of either two valves or a blow-off valve and a cock on each individual blow-off line. This conforms with the A.S.M.E. boiler code. A copy will be sent upon request.

THE OXWELD ACETYLENE CO., Chicago, Ill., has its new "Eveready" catalog ready for the public. The catalog is issued in sections, each devoted to a particular phase of "Eveready" equipment—welding and cutting blowpipes, regulators, accessories, etc. The "Eveready" line was formerly manufactured under the name of "Prest-O-Lite" apparatus by the Prest-O-Lite Co., and was extensively used in the metal trades. The Oxweld company took over the production and sales under the present name—Eveready—early in 1920, incorporating certain improvements in design lately developed in oxy-acetylene engineering. For the benefit of users of Eveready welding and cutting apparatus who desire special information on any particular phase of the industry, a series of small printed pamphlets containing matter excerpted from the Eveready instruction book and catalog. Among the subjects ready for distribution are: Directions for Operating Lead Burning Equipment, 12 pages; Directions for Operating Welding Equipment, 12 pages; Directions for Operating Cutting Equipment, 8 pages. Each pamphlet contains a detailed list of parts comprising the equipment treated. Copies are mailed free on request.

THE LOOMIS-MANNING FILTER DISTRIBUTING CO., Philadelphia, Pa., calls attention to a new catalog on its filters, which insure clean, safe, freshly-filtered water for all uses.

Choosing a Director For the Bureau of Mines

DESPITE the limitations of its name, the United States Bureau of Mines has a very definite and practical interest for the chemical and metallurgical industries. Mines belie their name unless they yield ores, and ores are without value unless metals can be produced from them economically. Nor is it the metallic minerals alone in which our industries are concerned; the non-metallics form the basis for the wide range of chemically-controlled industrial processes. The Bureau, therefore, serves a wide clientele and our interest in its welfare is almost personal in so far as we serve the chemical and metallurgical industries.

It has been an open secret for some time past that the present director of the Bureau, Dr. FREDERICK G. COTTRELL, plans to retire at an early date. His appointment on the resignation of the previous director, Mr. MANNING, was a merited honor. Moreover, it was advisable in the interest of maintaining the spirit of the organization and continuing its work until the proper man could be found to take the post permanently. Dr. COTTRELL neither sought nor desired the position, realizing that its administrative nature would not be wholly to his liking. His friends, likewise, felt that he would be wasting unusual talents of a high order in a place which offered little opportunity for the exercise of them.

Thus we are confronted with the necessity of securing a new director for one of the most important bureaus in the Department of the Interior. All will agree that the greatest care should be exercised in making the choice. The position calls for certain qualifications that are quite obvious. Primarily, we suggest that it seems appropriate that the director of the Bureau of Mines should be a mining engineer—one experienced in the theory and practice of mining, skilled in administration and organization, sympathetic with the related subjects of chemistry and metallurgy and having a broad view of the mining industry and its relation to the welfare of the country. In addition to these qualifications the incumbent should be in a position to make that sacrifice which a Government salary entails, and yet he must not be so secure in his independence as to have lost ambition and initiative.

A number of men suggest themselves in this connection—men of the type of POPE YEATMAN, R. M. RAYMOND, A. H. ROGERS or ARTHUR THACHER. Any one of these would bring to the office administrative ability and technical knowledge of a high order, combined with familiarity with all phases of the mining industry and a salutary knowledge of business.

We commend their consideration to those officials of the Government on whom will fall the responsibility of making the appointment.

Competitive Conditions In Commodity Markets

FOR many months past there has been what is commonly called a "sellers' market" in the majority of commodities. There has been competition, but it has been competition among buyers rather than competition among sellers. We cannot forget, however, how suddenly market conditions have changed at times in the past and there is reason therefore to expect that as many commodities are now swinging from the sellers' to the buyers' side the swing will be more or less violent.

If there had not been compensating influences the resulting tendency in recent times would have been for competition among manufacturers to become more violent each time the market turned against the sellers. One great compensating influence has been the growth of a feeling on the part of manufacturers that the individual must not do something that will prove harmful to the class. This is a substitute for the price agreements that are interdicted by the common law, written specifically into the statutes by the Sherman "anti-trust" act of 1890.

There is a serious question whether this co-operative feeling will be as prominent in the competition that is to come as it has been in the recent past. Some new influences have arisen. There has been much of what is called "profiteering" and in a given industry the amount of "profiteering" attempted by the individual sellers has varied.

In some industries there has been a wide division, some sellers having very plainly been profiteers, or seekers after the maximum prices obtainable from anxious and nervous buyers, while other sellers have been punctilious, even overscrupulous, in their efforts to avoid even the appearance of profiteering. As a result of these divergencies in attitude the men engaged in these industries are not in as close harmony with one another as was formerly the case, and the outcome of this situation may be a disposition to compete more keenly than in the last competitive period.

Another new condition is that both on account of profiteering and on account of the inability of some manufacturers to meet their customers' requirements in the past year or more many buyers are thoroughly disgruntled with their regular sources of supply and have registered vows that upon the first opportunity they will take their custom elsewhere. There will therefore be a great deal of "swapping" of customers. In many trade channels it has been the common practice among the majority of buyers to stick to a certain source of supply, their experience having been that thus they will best be "taken care of" in times of scarcity of the commodities involved. Many buyers now feel that instead of being taken care of they have been left entirely in the lurch or have been exploited to the limit—that in

other words the test has been pushed beyond the yield point and merely kept inside the breaking point, so that a permanent set has been acquired, and the permanent set means another source of supply for the future.

As to the attitude of sellers toward the buying trade, many have recognized frankly that after the period of famine and unreasonable prices they would have to buy their way into the trade again, and with large profits accumulated they are willing to devote a percentage of those profits to the buying process, to the selling of goods at a loss if necessary in order to purchase a clientele.

From a consideration of these circumstances it may be concluded that there are distinct possibilities of our seeing keener competition in some of the commodity markets than has been witnessed for a long time past or than was ever expected to appear again.

Who Is

A Chemist?

RECENTLY we noted in a valued contemporary of such high standing that it pains us to read them, two advertisements of chemical "positions vacant," which showed a striking lack of appreciation of what a chemist is.

One of these advertisements wanted "a graduate chemist or one who has *almost completed* the course" (the italics are ours); and then proceeded to state that analytical and investigation work in an almost unlimited field "in connection with manufacturing processes in many industries" was to provide "intensely interesting work, practically no routine." We wonder how that man who has only "almost completed the course" is to care for this field involving "manufacturing processes in many industries." He certainly would have to show unusual promise.

The other advertisement to which we refer wanted a chemist to do research work in one of our industries in which there is large opportunity for new investigation, but where extremely difficult problems are to be met. This position was to be filled by someone who was asked to state "age, education, past position, *if any*, etc." (Again the italics are ours.) We wonder how any man who has never held a position in chemical work before is to take advantage of the "good prospects" which this advertiser offers.

It is high time that our industries realized that a man fresh from college is not a full-fledged chemist. At this stage in ordinary circumstances he has not reached even the end of an apprenticeship. It is also high time that the chemists of the country made clear to the industries what they can do and who belongs within their learned cult.

It is almost a temptation to urge that no one should be permitted to style himself "chemist" unless he had passed certain qualifying tests. This very point was emphasized by Dr. M. L. CROSSLEY at the last meeting of the American Chemical Society in his address on "The Qualifications of Organic Chemists." Until we get some means of thus identifying the qualified members of our profession we are bound to be discredited in the eyes of industry, which inevitably through misunderstanding of the facts will seek out the man who has "almost completed the course" or will ask for the "previous position, if any," in the experience of one to engage in investigation work and in the solution of extremely difficult chemical problems.

Poor Fish

DR. JACQUES LOEB, of the Rockefeller Institute, has made many and profound studies of tropisms, and published several books on the subject. A tropism is a non-volitional act. Perhaps we can best explain it in the example of a species of fish with which Dr. LOEB was at one time experimenting. The fish were heliotropic—that is, the presence of light in a dark place compelled them to turn toward it. Thus if such fish are placed in a globe and if the globe be taken to a dark room into which a lighted candle or other light is brought they will forsake everything and keep their noses pressed against the side of the globe nearest the light. Move the light and all the fish will move to face it and stay right there as long as the light does; stay there until they float belly up on the surface with the life gone out of them. Disagreements, the search for food, love-making, and all the other joys and sorrows of fish life are forgotten or abandoned against what seems a grand passion of curiosity. Take the light away or make the whole room generally light again and the fish will swim about as before just as though nothing extraordinary had happened.

But if, while they are engaged in what seems like pop-eyed and perpetual wonder at the burning candle, we secretly lead into the water in which they swim a tube conducting carbon dioxide, we shall soon meet an amazing phenomenon. As the saturation of the water with CO₂ reaches a given point the apparent curiosity of the fish ceases, and one by one they give up their posts of observation and swim around and back and forth with no more reference to the burning candle or the single bright light than a society gold-fish. The little extra carbonic acid made them just like others. The phenomenon is an instructive example of photochemistry, and a demonstration of the theory of mass action in life.

Now suppose these fish were people and could talk. And suppose we should ask the biggest one why he looked at the candle.

"Why," he would reply, "I observed a new element in our world, and I didn't know what it was. So I made up my mind that I would not leave my post until I learned what it was, or at least what it would do. 'Here,' I said, 'is danger, and only death itself can drag me from my vigil until I know what it signifies!'"

Then we might ask him why he quit looking at it and gave up his quest. In reply he would declare that he finally reached the conclusion that the light was not dangerous; that it was a thing that did not concern the life of the colony. At this point he dismissed the subject from his mind and went about his business. Or he might offer any other reason *ex post facto*. An intimation as to the influence of carbon dioxide upon his opinions would offend him. He would want us to understand that he knew what he was about, that he was a fish of character, and not to be swayed in his opinions by carbon dioxide or anything else. If we were to ask him why the other fish also began to swim about freely at the same time as he, he would distend his chest and inform us with a dignified swish of his tail that he was probably not wholly without influence among his neighbors. Other fish would claim similar originality, fishy books would be written on the claims of the various leaders who brought the community back to "normalcy," and the history of the great light disturbance would become a subject of academic dispute and later a standard means of training the minds of young fish.

Now we're like that; very like it. For the past few years this country has been very prosperous and money has been easy to make. Thinking has hardly been necessary. We know of a young engineer who knew his business moderately well, but found it more profitable to work as a journeyman carpenter. Work has been very well paid. Hundreds of thousands of persons—men being scarce—have consequently declared that labor is the true source of all wealth; and there are tons of so-called literature to prove it. This means that, given a man, a horse and a cart, the cart and its earnings belong to the horse.

Gradually conditions are changing. The impossible has happened. American dollars have become so precious in comparison with foreign money that the foreigner refuses to buy of us. Ten dollars a day and bankers' hours—which are the hours banks are open rather than the hours bankers work—are still standards of payment for certain kinds of labor, but the jobs are getting scarce. Labor is beginning to underbid, and while we insist that labor is not a commodity and that every man and woman who works in an organization is part of its human staff, the fact remains that a little competition is a wholesome thing. There are limits to the earning power of a husky shoulder carrying a hod, especially in comparison with the earning power of thinking. Tropisms are less valuable than thoughts.

Now if our good dollars have got to be so valuable that the poor foreigner can't use them, then we must do something besides strut about and explain our glory and our might and our wisdom in making our dollars so valuable. When we do that we are merely displaying tropisms. What we need to do is some thinking, some real thinking, to get a line on the causes and to plan out a line of conduct that will be wise instead of foolish; intelligent instead of smart. A little season of meditation will do the best of us no harm. Then we may look inwardly and consider how much of what we think is mere tropism; conclusions reached because of influence, weather, situation, liking, etc., on the one hand, and on the other how much of our thinking is pure constructive thought. When hard times threaten it is impossible for us to get ahead by repeating old saws or by exercise of mere tropisms.

Need for Technical Advances In Carbon Black Technology

CARBON black is a highly important commodity. It is as essential as paper to the printing industry, every printed word almost being a composite of countless particles of it, which when mixed with linseed oil form an ink that is not tarry and instantly divides its oil with paper, giving a dry, adherent, black film over the wetted impression area. During the past five years the rubber industry has found it the superior compounding ingredient. The familiar black cord automobile tires are taking twenty million pounds, half the annual production and twice the amount consumed in printing inks, and promise an unlimited market.

West Virginia, the birthplace and home of the gas-black industry, as well as most all other states having natural-gas resources, does not welcome the prospect of having this fuel, so potential for industrial advancement and domestic comfort, all burned up in a few years to extract only one pound and a half of carbon black per 1,000 cu.ft. of gas. Legislation prohibiting the use of gas in this industry has failed so far on constitutional

grounds when tests of its legality were carried to the highest courts.

The remedy for the situation depends on the industry making a more satisfactory showing. Ninety-five per cent loss of the carbon in the original gas certainly looks bad, without even bringing up the subject of calories escaping in hundred per cent lots. That some effort has been made to improve the technology of the industry is well known. Many patents form a record of the creation of new ideas. Unfortunately, however, most of these were ill conceived and effected nothing. A tarry lamplblack or a gray coky powder are usually produced by all these would-be efficient processes.

In this issue we are publishing a full description of the channel process by ROY O. NEAL of the Bureau of Mines. In a subsequent number we shall describe the other commercial processes, and in the future we shall be looking for new developments to present to our readers. Every investigator on this subject should first acquaint himself with the processes now in use and then study the reactions and products, physically and chemically. Other sources of heat than the partial combustion of the gas may possibly be used, but not in thermally decomposing the gas into carbon and hydrogen. Pyrogenetic reactions take place with the hydrocarbon decomposition products, yielding tarlike particles which if further heated produce coke dust having no resemblance to carbon black. The reducing flame composition is undoubtedly necessary as well as its temperature, but the means of obtaining these are various and should be the basis for developments of the future.

A Note On Research

SUPPOSE, it was lately suggested, that GREGOR MENDEL, the Abbot of Brunn, had asked the head of his monastic order for land and labor and the privilege to carry on experiments in heredity. Of course, the request might have been granted, but he might also have been advised that it would be better to leave that kind of work to others. Such things often happen in the best of organizations. It may occur in a laboratory almost more easily than anywhere else.

We know that the sloppy man is a nuisance, we are fully alive to the hopelessness of results from disorderly minds, but we maintain, nevertheless, that the system and order which issue from incompetent administration is often the devil's own work. Research in industry points to a definite goal, but the trails found on the way are not to be despised. These trails are dividends, and to miss them is to miss the fruits of research. A proper division of work is necessary; great research laboratories must have analysts to speed up the achievement of men of originality; some persons are full of invention and short of accomplishment, while others can do only what they are told to do, although in this they are amazingly effective. But a false concept of system and order must not be allowed to kill invention or to discourage it. When a man of research has an idea it is well to advise with him and see if it cannot be brought to development with the help of his own enthusiasm. About the worst thing to do is to take the idea away from him and to kill his initiative because of some rule. Research is the occupation of a gentleman, and this fact should always be borne in mind. It is a very distinguished calling.

Readers' Views and Comments

More and Better Tools Needed

To the Editor of Chemical & Metallurgical Engineering

SIR:—There have been several references in CHEMICAL & METALLURGICAL ENGINEERING recently to a subject that has seemed to me one of the most important that could be considered by our technical societies, for indirectly it leads to a consideration of the proper function of the technical school and of the best training for technical students.

In the issue of Sept. 22, in describing the meeting of the American Chemical Society in Chicago, Major Howe's speech at the dinner was summarized as "a plea for better tools, among which the most important was the publication of tables of physical and chemical constants."

In the issue of Sept. 8 J. W. Richards writes at length under the head of "More and Better Tools Wanted" of the hiatuses in our knowledge of physical and chemical constants. Not long ago the American Chemical Society undertook a drive for \$100,000 to make a collection of constants for publication, a work which had been begun by the International Congress of Applied Chemistry with its three volumes of "Tables Annuelles."

I am inclined to believe that the most necessary thing at present is not so much further compilation of existing data as it is the determination of new constants. In preparing the last edition of my "Metallurgists and Chemists Handbook" I made some inquiry into the source of a number of the constants there published and was amazed to find how many of them were based on work done in the '80s and '90s.

Having had my attention called to one group of melting points, I tried to find later determinations than the early '90s and spent every evening for nearly three weeks in the Library of Congress in this attempt, without success. I am convinced that a very large proportion of our published data rests on work done between twenty and thirty years ago and that almost the entire field needs rechecking.

Who is to do it? It does not seem to be the place of the consulting engineer or of the private research or analytical laboratory. It is expensive and absorbing work, and contributes not at all toward meeting the H. C. L. On the other hand, the logical place for this work would appear to be the technical school, the college laboratory and the subsidized institution, such as the Bureau of Standards. There the professor or director has a large corps of assistants, his own living is already taken care of, and apparatus and chemicals are usually available without stint. Especially important for research work of the kind I have indicated is the first point. The professor can cover a large amount of territory in a short time, checking the results of different observers against one another, yet none of his assistants is wasting his time, for the training is valuable to each of them.

Yet apparently there is no longer thought in the technical schools of anything but "industrial fellowships." A friend of mine, head of a large chemical company, told me he recently received in one week pressing invitations from six colleges to establish industrial fellow-

ships. His own comment was, "I refused. Either I was hiring the professor, and it would be too cheap, or I was hiring an untrained student, and it would be too dear."

Again quoting from CHEMICAL & METALLURGICAL ENGINEERING, page 565 of Sept. 22, in referring to the Chicago meeting of the American Chemical Society, it says: "'The Qualifications of Organic Chemists' was presented by L. Crossley, chief chemist of the Calco Works, in which he, like Dr. Rose (and both Drs. Crossley and Rose have had wide experience as professors of chemistry before entering into industry), felt that so-called utilitarian work was of least value, while training in general principles in those studies which are necessary for the meditations of thoughtful men was of leading importance."

Isn't it about time to get away from the industrial fellowship idea, and the publication of constants idea, and leave the former to the practicing chemical engineer and the latter to individual enterprise, and give a little attention to research work on the determination of some of the needed constants? It will probably be said that I write "as one whose ox is being gored." Who else is there to write on the subject but those who are vitally interested in it?

New York City.

DONALD M. LIDDELL.

There's Trillions in It!

To the Editor of Chemical & Metallurgical Engineering

SIR:—The Exposition brings to light all sorts of unexpected things. A gentleman who owns 6,400 acres of shale land showed a report that he had received from a technical "expert." He refused to give up the expert's name, so I am restricted to the mere record of his glorious imagination, which seems too rich, too active, too venturesome to be permitted to blush unseen. If we could only transform this imaginative energy into foot-pounds, I believe we could run a blast furnace with it. Like all men of similar (but lesser) gifts, he presented two sets of figures in his estimate of the industrial value of the gentleman's property, which he calls respectively "high" and "average."

The value of the shale per ton is declared to be:

	High	Average
Oil, 75 gal., Penna. grade	\$12 50	\$7 50
Gold	65 00	10 00
Silver	33 15	5 00
Platinum	86 00	8 00
Potash	12 00	6 00
Ammonium sulphate	6 00	3 00
Production cost...	\$214 65	\$39 50
	5 00	5 00
"Net value" per ton	\$209 65	\$34 50

The report continues: "Actual surveys show an average surface deposit of 1,000,000 tons of shale per acre, or an average profit of \$34,500,000 per acre. The total tract is 6,400 acres and the prospective earnings therefore 6,400 times the above sum." Here's where we begin to see wealth! We are considering only the surface deposits and we can't tell how much more there may be underneath. But taking only the so-called

"average" or conservative figures we have a prospective clean-up of twenty-two billion, eight hundred million dollars. That's something like! It gives a man a chance to make John D. Rockefeller look like thirty cents. And these, remember, are the conservative figures. Using the "high" estimates, the happy investor can see value up to one trillion, three hundred and forty billion, with a little matter of 760 million dollars on the side.

The only prospectus to compare with this that I have ever seen is one that I came across a score of years ago when the trusts were forming, and that is a mere bagatelle in comparison. It reads:

AMERICAN RABBIT FARM CO., UNLIMITED,

to be organized under the laws of the Philippines
Prospectus

Rabbits commence breeding at six months and have drops of eight every three months. It is proposed that we commence with ten pairs, ten males and ten females, which exclusive of land will call for an investment of four dollars, resulting in the following product:

3 months	80	1 year, 3 months	4,160
6 months	160	2 years	279,680
9 months	880	3 years	306,446,720

This product can be sold in the market certainly at five cents each, giving a gross income in three years of \$15,322,366, to be deducted from which are the following expenses:

Rent of land, per annum	\$4,000	\$12,000
Superintendence, per annum	2,000	6,000
Feed (estimated), per annum	2,000	6,000
		\$24,000

This leaves a net profit on a four-dollar investment of over fifteen million, two hundred and ninety-eight thousand, three hundred and thirty-six dollars (\$15,298,336) in three years.

The Company will issue Capital Stock to the amount of four dollars divided into 400 shares, par value one cent.

Subscriptions are invited to the Capital Stock of the Company at par.

The right is reserved to allot less than the amount applied for hereunder.

When I think of poor old Colonel Sellers and his eye wash I—why, say, Mr. Editor, I just pity him!

New York City.

MARTIN SEYT.

Data on Operation of Continuous Type Lime-Soda Ash Water Softener

To the Editor of Chemical & Metallurgical Engineering

SIR:—I wish to present a number of corrections to be applied to the article on "Data on Operation of Continuous Type Lime-Soda Ash Water Softener," which appeared in your journal of Sept. 15, 1920, page 526.

The paragraph on "Analytical Data Determinations" has the following statement: "Since the water was acid in character, these readings were obtained on the raw water with the exception of C." This statement is wrong chemically and should be: "Since only the methyl reading could be obtained on the raw water, the carbonate hardness was due to bicarbonates alone."

In the paragraph on "Interpretation of Data," some one inserted a statement as follows: ". . . the CaCO₃ forming a gelatinous precipitate." This is not quite true and should be: ". . . the CaCO₃ forming an amorphous precipitate which slowly crystallizes."

Cincinnati, Ohio.

H. C. FISHER.

The Type of Explosive in Wall Street Explosion

To the Editor of Chemical & Metallurgical Engineering

SIR:—One of the most important points in the Wall St. explosion is to determine the type of explosive actually used and perhaps by discovery run down the investigation to a single track and finally indentify the plotters of this crime through this channel. The first question that interests the public is, "What kind of explosive did they use, and where did they get the supply?" From all the facts, materials and observations in possession of the authorities, one should by systematic and scientific examination and elimination arrive at an accurate conclusion, quite possible under similar circumstances, and thus determine whether any TNT, dynamite, picric acid, smokeless powder, black powder and other explosives were used in this criminal exploit.

The amount of property damage done by this explosion is surprisingly small. With the exception of window smashing there is no material loss of property over \$150,000. Furthermore, instead of reducing the wagon carrying the explosive into splinters, which would be the case with powerful explosive like dynamite, picric acid or TNT, the explosion simply broke it into small pieces large enough to be collected and reconstructed. This evidence shows on its face either that the explosive was not powerful or the quantity used was very small, say not exceeding 50 lb., and probably nearer 25 lb.

All explosives are recognized by their physical and chemical characteristics and are easily differentiated from one another by the report or sound of explosion, flame, smoke, fumes and the residue they leave behind. For instance, a smokeless powder burns and explodes without smoke, leaves no residue and has a light yellowish flame; on the other hand, TNT and picric acid burn and explode with a deep orange yellow flame, dark fumes, but leave no residue. These last two explosives explode with sharp and deep detonation and when exploded in the open carry loose particles of TNT and picric acid in the air and color the fumes somewhat yellow. All the evidence obtainable in this case indicates that smokeless powder, TNT and picric acid were not used in the explosion, since no black fumes were observed and no deep orange yellow flames, and, most important of all, such explosives would not leave any residue. In the Wall St. explosion the explosives left a residue, after the explosion, which was scattered all over the ground and some of it was attached to the window weights which actually came in contact with explosive matter.

After eliminating TNT, picric acid and the smokeless powder there remains black powder, dynamite, nitro-starch and chlorate powders, which leave a distinct residue after the explosion. Although the black powder leaves a residue, its use is not likely in this case, because it is a weak explosive and leaves behind such a large volume of black smoke that it can be easily recognized by almost everybody.

Dynamite upon explosion leaves behind a residue consisting of sodium carbonate, sodium sulphate and other sulphur and soda compounds, if sulphur was used in the manufacturing process.

Nitro-starch explosive leaves behind the same ingredients as dynamite. The chlorate powders leave sodium and potassium carbonates, sodium and potassium sulphates and the chlorides and the sulphides of the same

salts. Either potassium or chlorine in the residue will indicate at once the presence of chlorate powders. One of the principal points testified by witnesses was that the explosion sound was not sharp and short as dynamite but rather long and rumbling. As a matter of fact, dynamite explodes with a short and sharp detonation, a short flame and with only gray-white fumes. Again, 25 lb. of dynamite would do more damage than was caused in the Wall St. explosion. Moreover, it would make a big cavity in the street just under the wagon in spite of the fact that the explosive was placed 3 ft. from the ground. Nitro-starch explosives are principally made by one manufacturer, and its sales could be easily traced by the authorities. Therefore it is unlikely that the plotters used this last explosive at all.

Chlorate of potash and soda are the only ingredients of this explosion that remain and fall under suspicion. There is no manufacturer of explosives in this country regularly making powder containing chlorates or perchlorates. Chemical examination of the residue has indicated conclusively the presence of potassium, chlorine and antimony. It is possible that the plotters of this crime bought their raw material in small quantities from chemical houses, drug stores, fireworks makers, etc., and by mixing them with charcoal, nitrobenzene, sulphur and antimony they concocted an explosive imperfectly balanced but strong enough to create this disaster. Had the explosive been a regularly manufactured product it certainly could have done more damage than was experienced in Wall St.

Another important point on which all the witnesses agreed is the length of the flame that came out from the explosion, burning window shades seven stories high. Now, there is only one explosive that has such a long flame, and that is the chlorate explosive.

Most people have never seen an open explosion of any explosive, hence they have no perfect idea as to the physical characteristics of the reaction. While their testimony is not contradictory, certainly it is not constructive. Estimates of the flame, sound or the fumes are widely apart. It would be a very useful as well as a practical procedure to take these witnesses in an open space and explode before them different charges of explosives, say 2 lb. each, from a safe distance (200 ft.), and discover whether their memory as to the character and the intensity of the sound, the flame, the smoke and fumes could be refreshed. While the chemical examination of the residue indicates the presence of the chlorate explosives, a practical demonstration such as mentioned above would strengthen by physical observations the conclusion brought about by chemical examination.

*This matter deserves the attention of state and Federal authorities and it is to be hoped that they will carry out these practical suggestions in order to satisfy the demands of a careful investigation.

In conclusion I would re-emphasize the fact that the determination of the type of explosive used in the explosion can thus be made by two tests.

1. Chemical examination of the residue.
2. Physical examination, including the testing of the evidence from witnesses.

In the chemical test, the residue consists of a comparatively few number of ingredients, therefore this examination is short and comparatively easy. The physical examination includes reproducing the sound, the flame and the fumes, which can be determined from

persons who actually saw the explosion, and the same can be repeated by practical test in the field.

From all the facts in my possession one can safely conclude that the explosive actually used in the Wall St. explosion was not a well-made manufactured product, but was concocted by the plotters of the crime and made up of such ingredients as they could buy. The explosive was not confined in any stout metal container or bomb, but it was put probably in a wooden box and covered by iron slugs and window weights. That is the reason why the damage was mostly caused by concussion and expansion of gases rather than by metal projectiles or fragments.

It is of course possible to compound explosives containing a number of materials such as TNT, picric acid, nitrobenzene, chlorates and nitrates. An explosive of this type would not show any decided characteristics and the examination of its ingredients would not lead to anything definite, but it is my opinion that even if such a mixture was used the basic ingredient of the explosive used in Wall St. consisted mostly of chlorate. If small quantities of other explosive materials were used they did not materially change the character or the power of explosion.

A Suggestion to Exhibitors

To the Editor of Chemical & Metallurgical Engineering

SIR:—The recent Chemical Exposition can scarcely have failed to impress both the technical man and the layman by its extent and by the care with which the various exhibits were prepared. As an advertising medium for the chemical industries and as a method for presenting the latest in chemicals and equipment it was excellent.

It is all the more deplorable that so many of the exhibitors placed their booths in charge of salesmen rather than under the direction of men who were thoroughly qualified to explain their respective displays. In at least half a dozen instances, to my own knowledge, well-intentioned inquiries about exhibits were answered by statements which would have been ludicrous had they not displayed such gross ignorance of facts. Surely progress in the chemical industries will be enhanced as much by the liberal use of technical men at the expositions as by the use of those men trained in salesmanship only.

AILEN ABRAMS.

Aluminum Trade of Japan

Although the aluminum industry is now well established in Japan, most of the forty-four manufacturers conduct business on only a small scale, chiefly for home consumption, states a recent article in the *World Salesman*. The variety of articles manufactured is comprehensive, including all kinds of cooking utensils, candlesticks, pipes, cigarette cases, alcohol lamps, army canteens, bottles and various kinds of castings. Japan is entirely dependent upon the United States and England for raw material in connection with this industry, though at present, in co-operation with an American aluminum company, plans are under way for the erection of a plant in Fukui Prefecture which, with the help of experienced American workmen, will later be able to supply the raw aluminum material needed. In 1918 imports of ingots from the United States were 1,466,967 kin (kin — 1½ lb.) valued at 1,662,471 yen, and from England they reached 12,346 kin.

of the Cleveland, Ohio

Cleveland Meeting, American Electrochemical Society

**Report of Technical Sessions, With Discussion of Papers on Electrometallurgy and Electrochemistry—
Visit to the Nela Research Laboratories and Industrial Plants—
Banquet and Other Social Features of the Meeting**

THE thirty-eighth general meeting of the American Electrochemical Society was held at Cleveland, Sept. 30, Oct. 1 and 2, with headquarters at the Hotel Statler. In spite of the fact that Cleveland is centrally located, and further, that this was the first meeting of the Society in that city, the attendance was not as large as usual. Whether this is to be ascribed to the increase in railroad fares or to some other cause is not apparent. Certainly the technical sessions which are herewith reported fully, were quite as lively and interesting as usual and the hospitality and entertainment afforded by the Cleveland members, assisted by the Cleveland Engineering Society, elicited approval and congratulations. In fact the refreshment provided was of a distinguished order.

Social Features

A complimentary smoker was tendered by the National Carbon Co., at which entertainment was provided by professional talent and members of the Society. The success of the banquet was assured by the presence of a large number of ladies and by a short but imposing list of after-dinner speakers. Dr. A. W. SMITH, professor of chemistry of the Case School of Applied Science, presided as toastmaster, and responses were made by Dr. CHARLES S. HOWE, president of the Case School of Applied Science; Dr. W. S. LANDIS, president of the American Electrochemical Society; Dr. CHARLES F. BRUSH, inventor of the arc light, and Dr. E. P. HYDE, director of the Nela Research Laboratories.

Taken as a whole, the meeting was one of unusual

interest, and the Society is indebted to Dr. N. K. CHANEY, chairman of the local committee, and his efficient coworkers of the Cleveland Engineering Society. The visiting ladies will long remember the attractive program arranged for them under the direction of the Ladies Committee, headed by Mrs. E. R. GRASSELLI.

First Technical Session, Thursday

HEAT LOSSES THROUGH ELECTRODES

The first technical session was held in the large hall of the Hotel Statler on Thursday morning. M. R. WOLFE and V. DE WYSOCKI, of Lehigh University, gave an account of their measurements on the "Heat Losses Through Electrodes." A six-ton Heroult furnace was provided with three electrodes, each 38 cm. in diameter and made of ordinary amorphous carbon. In working up the calculated heat flow, Hansen's value for thermal conductivity, 0.016 cal. per second per centimeter cube per degree C., was used. Each electrode was provided with a water-cooled ring immediately above its exit electrode, the average rise in temperature of the water cooled connection at varying distances above the roof. The grams of water flowing per second was 427.8 per electrode, the average rise in temperature of the water 22.9 deg. C., and the sum total of heat in the cooling water for the furnace was 123.1 kw. Since 650 kw. was supplied to the furnace, the total electrode loss was therefore 18.7 per cent of the power used. Of this total, 18.5 kw. was absorbed by the upper cooling contact holders, and 104.6 kw. by the lower water-cooled rings.

The paper was discussed by Messrs. TURNBULL, HERING, FINK and RICHARDS. It was pointed out that Hansen's value, 0.016, was determined about fifteen years ago and that in the meantime the conductivity of the carbon electrodes had changed. A redetermination of this value seemed advisable. At all events, the resistivity of the electrodes under investigation ought to be included in Wolfe and Wysocki's report. Furthermore, it was argued that the 104.6 kw. absorbed by the lower water-cooled rings was partly derived from the roof and that therefore the value reported for the electrodes was too high.

HEAT CONTENT OF STEEL AND SLAG FROM AN ELECTRIC FURNACE

A. M. KUHLMANN and A. D. SPILLMAN, of Lehigh University, reported on a series of calorimetric determinations of the heat content of liquid steel and liquid slag from a 6-ton Heroult steel-casting furnace at the works of the William J. Wharton, Jr. Iron & Steel Co. A Fery radiation pyrometer was used for high temperatures and either a platinum-iridium thermocouple or platinum resistance thermometer for the lower temperatures. The slag analyzed 23.5 per cent SiO_2 , 24 per cent FeO , 1 Al_2O_3 and 42 per cent CaO . The mean specific heat of the solid slag up to 810 deg. C. was found to be $0.133 + 0.00011t$ and the heat content, Q , $0.133t + 0.00011t^2$. The value of Q for liquid slag was found to be 476 cal. at 1,190 deg. C. and 520.5 cal. at 1,250 deg. C. The heat content of the liquid steel (0.1 per cent C, 0.2 per cent Mn) was determined and at 1,900 deg. this was found to be 325 cal.

In the discussion of the paper that followed Dr. CARL HERING pointed out that in dropping the molten slag or steel into the water of the calorimeter, considerable steam was evolved which would naturally lead to errors in the thermal values. W. S. LANDIS referred to errors that would arise when using an optical pyrometer in making temperature determinations of liquid slag on account of the emissivity of the slag depending largely upon its composition. Dr. J. W. RICHARDS agreed that probably the values reported were high and that the temperature of the liquid steel was nearer 1,800 deg. than 1,900 deg. Dr. HERING suggested that the molten steel or slag be poured into lead or into a metal cup or crucible and this introduced into the calorimeter, thus largely avoiding the formation of steam.

ELECTRICAL RESISTIVITY OF REFRACTORIES

The third paper of a series on the physical properties of specialized refractories was presented by M. L. HARTMANN, A. P. SULLIVAN and D. E. ALLEN, of the Carborundum Co. research laboratory. The first two papers were read at the Boston meeting of the society. This contribution dealt with the electrical resistivity of refractories at high temperatures.

In the design of electric furnaces it is important to know the electrical resistivity of the refractories used in those portions of the furnace which contain, or come in contact with, the electrodes or resistor material. Practically no data have been published on the resistivities of commercial bricks except those by Stansfield, McLeod and McMahon.¹ These investigators determined the resistivities of silica, chrome, magnesia and fireclay from 600 to 1,565 deg. C. Hering² has compiled from the literature the resistivities of many substances, but these do not include commercial refractories.

Using a method similar to that employed by Stansfield, McLeod and McMahon, the authors determined the electrical resistivities of nine commercially used refractories, at temperatures up to 1,500 deg. C. Measurements were taken while heating up slowly and while cooling down slowly, the thermocouple measuring temperature being outside the specimens. The amount of temperature lag thus involved was approximately determined. The results, which are summarized in the table, are necessarily only approximate, but show the relative resistivities of the different materials and the general order of magnitude of their resistivities up to 1,500 deg. C.

The paper brought forth considerable discussion in which Messrs. SAUNDERS, FINK, HERING and RICHARDS participated. It was pointed out that resistivities of refractory bricks should always be accompanied by a chemical analysis and grain size. Furthermore, whenever possible the binder used in the brick ought to be taken into account. A silica brick with 97 per cent SiO_2 and 3 per cent of a highly conducting binding material might have decidedly lower resistivity values than a 93 per cent SiO_2 brick with a low conductivity binder.

DETERIORATION OF NICKEL RESISTORS

The high cost of nichrome wire and the onerous conditions attached to a license for its use led F. A. J. FITZGERALD and GRAN C. MOYER to study the use of nickel wire as a resistor in electric furnaces. It seemed possible that for some purposes nickel wire might prove to be a suitable substitute in spite of its high thermal coefficient of electric resistance, for this disadvantage can be overcome, and its deterioration by oxidation, since this, with reasonable precautions, can be diminished so as to give a fairly extended life.

It was found, however, in some heating devices that nickel resistors broke down after very short service, for although there was no appreciable oxidation the resistor wire had become so very brittle that the slightest bend would break it. This effect was thought at first to be due to carbonization of the nickel, since the wire had been embedded in cement and a heat insulator

containing carbonaceous matter. Further investigation showed that the real cause of the trouble was sulphur, which makes nickel wire brittle even at low temperatures, while the effect is very marked and rapid at temperatures above 500 deg. C.

When precautions are taken to prevent reaction with sulphur, nickel wire seems to stand up well as a resistor.

In the discussion of the paper, the question was brought up whether sulphur was the only cause of brittleness in nickel wires. To this Mr. FITZGERALD replied that they had confined themselves to the effect of sulphur and that analyses of the samples supported their conclusions. For example, in the original nickel sample only a trace of sulphur was found, but the sample subjected to sulphurous fumes for ninety-six hours contained 0.054 sulphur. C. P. MADSEN referred to the patent situation on the use of nickel as a resistor and to his elaborate experiments to determine the best refractory covering for incandescent nickel wire. Pure oxides were in general preferable to silicates. Dr. FINK referred to the bad effect of carbon on the ductility of nickel and the beneficial effects of manganese when added to the extent of about 2 per cent.

THE SÖDERBERG CONTINUOUS ELECTRODE

Dr. JOSEPH W. RICHARDS submitted a second report on the progress of the Söderberg electrode.* He described and commented upon the success of the three-phase installation of the Söderberg self-baking electrodes in operation at Anniston, Ala., since July 2 of this year. The furnace is rated at 1,800 kw. and is used for the manufacture of ferromanganese. An open top furnace of the usual ferro-alloy type is used. The working space is 12 x 20 ft., elliptical in shape. The three electrodes are each 32 in. in diameter and extend from the furnace up into the tamping house, which is 12 ft. above the charging floor. The total length, when a new section has just been added to the top, is 24 ft. and the weight, exclusive of the holder, about 13,200 lb. per electrode. The casing is formed of No. 18 sheet iron riveted together to the correct diameter, and provided with inwardly directed partitions, as previously described. One section 46 in. long weighs approximately 110 lb., or 2.4 lb. per in. In the baked electrode there are 18 parts of carbon per 1 part of iron shell. A new section may be required per electrode every five to fifteen days, according to the nature of the ore being reduced in the furnace and the current taken by the electrode. In the straight-line three-phase arrangement, it is almost impossible to get each electrode to take the same current, so the consumption will be somewhat different on each electrode. Holders and electrodes are suspended by wire cables controlled by hand.

The ore used was Caucasian di-oxide ore of high grade, 56 per cent manganese, with not sufficient iron for producing 78 per cent ferromanganese and not sufficient silica to give a proper slag volume in the furnace. Analysis of the ore showed 4.67 per cent moisture. The dried ore contained: Manganese 56.35 per cent, iron 0.80, silica 5.04, alumina 1.40, lime 1.90, magnesia 0.84, baryta 0.93, manganese dioxide 88.34, manganese monoxide 0.65.

Iron turnings were added, and picked return slag put back in the furnace to increase the slag volume. The average carbon consumption was 6.6 kg. per 1,000 kw.-hr. The ore was so fine in structure that it packed badly in

the furnace, causing frequent cratering. It was a difficult charge to work, requiring frequent stoking. Another furnace in the same plant, working the same ore with square baked electrodes, had the same difficulties from the packing of the charge.

The advantages for the Söderberg electrodes are:

1. Absolute continuity of operation, as far as the electrodes are concerned.
2. Smaller consumption of electrode carbon per given power supplied to the furnace.
3. Lower cost of electrode per given power supplied to the furnace.
4. Lower power losses in the electrodes.
5. Greater regularity of running of the furnace, and therefore less wear and tear on the workmen and the management, and greater uniformity of product.

In commenting upon Dr. Richards' report ROBERT TURNBULL suggested that it is more practical to state electrode consumption in terms of pounds per ton of product rather than pounds per 1,000 kw.-hr. The consumption per 1,000 kw.-hr. might be very low and yet the consumption per ton of product very high. The question was also raised whether or not the tamping house would interfere with the free operation of a furnace of the Heroult type. In reply Dr. Richards read a cablegram just received from Norway advising of the successful operation of a steel furnace equipped with Söderberg electrodes. Tests are furthermore under way in the substitution of the Söderberg for the graphite electrodes used in the manufacture of aluminum. In the case of the steel furnace, the Söderberg electrodes are made up and added in sections, thus permitting of the tilting of the furnace. At Anniston the ferromanganese furnace operated twenty-eight days during August with but thirteen minutes shutdown on account of electrodes. The carbon consumption was 14.2 lb. per 1,000 kw.-hr. A ferrosilicon furnace in Norway equipped with Söderberg electrodes is consuming but 12.6 lb. of carbon electrode per 1,000 kw.-hr. This compares favorably with Mr. Turnbull's figure of 11.6 lb. per 1,000 kw.-hr. when using standard carbon electrodes (65 lb. per ton of 50 per cent ferrosilicon).

ELECTRIC FURNACE SMELTING OF MANGANESE ORES

A paper of the above title, originally presented by E. S. BARDWELL at the spring meeting of the society in Boston (see CHEM. & MET. ENG., vol. 22, page 681, for the full paper), was brought up for discussion.

PHENOMENA OBSERVED IN ELECTRIC FURNACE ARCS

The last paper of the Thursday morning session was by J. KELLEHER, of the University of Toronto, on "Phenomena Observed in Electric Furnace Arcs."

In the first set of experiments a bath of iron-nickel alloy covered by an acid calcium silicate slag was melted in the electric furnace. To observe the arc under these various conditions the following arrangement was employed: An opening was made in the front wall of the furnace. The opening was then covered by a piece of sheet iron in which a pinhole had been drilled. The light emerging from the opening was allowed to fall on a ground glass screen, which was moved backward and forward until a clear inverted image of the arc was obtained, thus permitting sketches and even photographs of the arc to be made. In the normal arc, that is, one where the movable electrode is the negative pole, the flame apparently flows from the electrode to the slag, depressing the slag and flaring out to all sides, or to one

*For first report see CHEM. & MET. ENG., April 21, 1920, p. 732.

side. An arc length of about 3 inches could easily be maintained. Under these circumstances the arc was silent.

As soon as the polarity of the furnace was changed, a very unstable arc appeared. This arc started below the surface of the slag, the flame moving away from the slag surface and projecting particles of slag into the air with considerable force. The length of this arc could barely be maintained at a greater length than 1 in. The noise of the arc was loud and spluttering.

It had been noticed that if with a normal arc large currents were allowed to flow, the arc became noisy and had a tendency to quench itself, even at comparatively short lengths.

The results of numerous observations might be summarized as follows: A disturbance takes place in the furnace running on normal load with an arc when the electrode is near the slag surface, tending to increase the current. The regulator immediately starts to raise the electrode. The large arc maintains its original shape until the length becomes so great that it is ruptured. Immediately all the lesser arcs move away to the outer edge of the electrode, leaving about 75 per cent of the surface of the electrode end bare. This causes a rapid and large decrease in the current flowing, and the regulator commences to lower the electrode.

These arcs do not spread across the surface of the electrode until the surface of the slag is almost reached. They then suddenly spread over the whole electrode surface, causing a sudden and large increase in current, and the whole cycle of events is repeated.

A number of sketches were shown to illustrate the various appearances of the arcs.

Dr. HERING in discussing the paper referred to the rectifying action of the arc.

Friday Morning at the Case School of Applied Science

INDUSTRIAL APPLICATIONS OF ELECTROLYTIC CONDUCTIVITY MEASUREMENTS

The use of accurate conductivity measurements on electrolytes, to determine therefrom variations in composition, such as using a salt solution of known conductivity as a solvent for sugar, and determining the amount of sugar by its effect in increasing the resistivity of the solution, was described by EARL A. KEELER. Such measurements may be useful methods of control in chemical manufacturing operations, such as boiler water concentrations, degree of evaporation, losses in tail-races, acidity of liquors, etc.

It is well known that many chemical processes or reactions can be followed and investigated by the measurement of the potential difference or changes in potential difference between two electrodes immersed in the solutions involved. These potential changes result from the changes in magnitude or nature of the ionic concentrations in the solutions undergoing the reaction or chemical changes. The determination of hydrogen ion concentration by means of the potential difference existing between a hydrogen electrode and calomel cell is the most notable example of this type of measurement.

While the technique of the hydrogen ion method has been highly developed during recent years, considerable work must be done to develop and design apparatus that will be satisfactory under the severe requirements of industrial use. Development work along this line is

progressing rapidly, and it is expected that material will soon be available for a paper on the "Industrial Applications of Hydrogen Ion Determinations."

In commenting upon Mr. KEELER's results President LANDIS briefly described a practical installation at the cyanamide plant at Muscle Shoals. Cylindrical nitric acid containers were lowered into the wells in sections and in order to detect any possible leakage of acid several pairs of electrodes were placed a short distance away from the cylinders. The electrodes were connected in series with an incandescent lamp and a current supply. The lamp would light up automatically as soon as acid leaked out near the electrodes. E. R. MORTON criticized the method of calibrating the Leeds & Northrup cells used by Keeler. They were all standardized by comparing them with another standard cell kept by the company in its factory. There ought to be some quantitative measurement independent of this comparison method.

A NEW FORM OF STANDARD CELL

A new portable standard cell which is a satisfactory laboratory standard was described by C. J. RODMAN and THOMAS SPOONER. It is of the cadmium type of special design with the usual ingredients but having a container of hard glass with tungsten leads. Instead of the common H-type a compact concentric arrangement has been devised possessing a number of advantages. This cell is made either saturated or unsaturated, and other combinations besides the standard cadmium formula may be used in the present cell blank if desired.

The cell is a marked improvement over older types and is an interesting application of the tungsten seal in pyrex glass.

FARADAY'S LAW AT THE CATHODE

Since the direct invariable relation between electrical current and chemical quantity subsists only at the anode, and the present theory of electric current postulates current passing, as negative electrons, only toward the anode, is it not logical and reasonable to assume that the direct relation between electrical current and chemical quantity is true only at the anode?

On the other hand, the relation at the cathode being variable, and therefore probably indirect, Prof. J. W. RICHARDS declared that it was logical and reasonable to assume that this relation is not electrochemical but is more properly designated as chemical only—that is, it is governed by the chemical relation between the quantity of anodic element set free at the anode and the cathodic element. In other words, when the electric current sets free electrochemically at the anode a given amount of the anodic element or constituent of the compound, an amount directly determined by the electrochemical relations and Faraday's law, there is set free at the cathode that amount of the cathodic constituent which was chemically combined with the amount of anodic constituent liberated. This relation is chemical, and determined by the chemical equivalents of the substances in question, and subject to the variable valence of the cathodic element just as in any simple chemical decomposition.

If the above reasoning is valid and logical, it would follow that Faraday's law will apply fundamentally only to the anodic constituent, which is directly related to the quantity of negative electrons traveling to the anode; it would correspondingly follow that Faraday's law does not directly apply to cathodic constituents,

but only indirectly through the chemical relation that the quantity of cathodic element liberated is simply that which was chemically combined with the quantity of anodic constituent liberated, and is only thus indirectly related to the quantity of electric current passing.

Messrs. HERING, MADSEN and LANDIS participated in the discussion and it was generally conceded that Dr. Richards' interpretation of Faraday's law was an excellent one, although perhaps not entirely new.

Saturday's Technical Session

The third technical session was held Saturday morning and was devoted to papers on electrolytic refining, electroplating and corrosion. In the electroplating art considerable attention has been paid to brass plating and remarkable results have been achieved within the last few years.

ELECTRODEPOSITION OF BRASS FROM CYANIDE SOLUTIONS

After discussing the theory of the co-deposition of two metals from solution, ALFRED L. FERGUSON and EARL G. STURDEVANT presented the results of a series of experiments upon the deposition of brass from cyanide solutions. Cast zinc and electrolytic copper anodes were used so that the single potentials of each metal could be determined. The following conclusions were noted:

Increase in the ratio of copper to zinc in the solution increases the percentage of copper in the deposit. A solution in which the ratio of copper to zinc is 4.2 gives a deposit of about 65 per cent copper (ratio 1.9). Solutions of high metal content are more satisfactory than dilute solutions. A solution containing 35 g. of metal per liter, in the above ratio, gives satisfactory deposits. Increase in temperature decreases cathode polarization and consequently increases the percentage of copper in the deposit. Increase in current density produces a gradual decrease in the percentage of copper in the deposit. At current densities greater than 0.3 amp. per sq.dm., the deposit becomes granular, non-adherent and dull in color. Increase in free cyanide does not increase anode efficiency, but does decrease cathode efficiency. Its influence on the percentage of copper in the deposit is variable.

Slightly acid substances increase the percentage of copper in the deposit. A weak acid may be used in place of any of the acid substances that have been recommended. Slightly alkaline substances decrease the percentage of copper in the deposit. The presence of slightly alkaline substances is beneficial in that it improves the appearance of the deposit. Neutral substances have no influence on the deportment of the cyanide brass plating solution.

Brasses which vary in composition from 62.3 to 85.0 per cent of copper dissolve as such anodically. The efficiency of corrosion is about the same as that of copper. Decided depolarization of zinc by copper takes place and makes possible the deposition of brass from solutions in which the potentials of the two metals are not equal. Electrodeposited brasses which vary in composition from 37.6 to 82.0 per cent copper give nearly the same potentials in a plating solution. These potentials are nearer to that of copper than to that of zinc.

Mr. HOGABOOM dwelt at length upon the importance of controlling and regulating conditions during deposition of brass. He has developed a commercial process for coating steel and iron with brass and the results

are so good that it is practically impossible to distinguish the brass plated articles from those made of solid brass. Dr. BLUM of the Bureau of Standards criticized Dr. Sturdevant's thesis from the theoretical point of view. He did not concur with him in all of his conclusions.

TIN PLATING FROM ALKALINE TIN BATHS

FRANK C. MATHERS and WILLIAM H. BELL discussed the possibility of producing smooth non-crystalline deposits of tin from sodium stannite baths by the use of addition agents. Although it was found that balsam copaiba and rosin gave good deposits, the experiments were unsuccessful in that the sodium stannite baths gradually oxidized or deteriorated to such an extent that continued satisfactory deposits could not be obtained. No method of regenerating the baths was found. For this reason, the bath is not recommended for tin plating. It would be unreasonable to bother with sodium stannite when one can use the stannous sulphate bath, which gives splendid deposits without any important difficulties.

Although the authors did not pass favorably upon the alkaline bath for tin plating, Mr. HOGABOOM, in discussing the subject, related his success with the bath at one of the Government plants. He used an electrolyte containing stannic chloride and sodium hydrate and obtained excellent results. The plate was very smooth and adhered perfectly. Of course only thin deposits were required. Messrs. FINK and MADSEN referred to misleading statements in the literature as to the rating of a plating bath. It was suggested that hereafter authors include the limiting phrase such as "for heavy plates" or "for thin plates" in passing upon the quality of a plating bath. The tin chloride electrolyte gives good thin deposits but very loose crystalline heavy deposits.

ELECTROLYTIC REFINING OF TIN

EDWARD F. KERN presented the results of a series of experiments on the electrodeposition of tin. The electrolytes used were stannous-sodium chloride, stannous fluoborate, stannous naphthalene-sulphonate and stannous sulphate.

When no addition agents were used, the best cathode deposits were obtained from a stannous sulphate solution containing 6 g. tin and 7 g. H_2SO_4 per 100 c.c. The deposits formed in stannous naphthalene-sulphonate electrolyte (made from the corresponding copper solution by replacement with tin) were second best; and the deposits from stannous-sodium chloride electrolyte and from stannous fluoborate electrolyte were third best. In no case were adherent, smooth cathode deposits formed, with no addition agent present.

In order to produce satisfactory cathode deposits of tin in the electrolytic refining of tin, it seems to be necessary to add suitable addition agents to the electrolyte. It was found that the presence of peptone and of gelatine was beneficial; the presence of aloin was beneficial only with the fluoborate electrolytes when present in proportion of 1 g. per 1,000 c.c. solution. The most satisfactory cathode deposits were formed in the stannous fluoborate and in the stannous sulphate electrolytes when gelatine or peptone was present in the proportion of 1 g. per 500 to 1,000 c.c. of electrolyte. In the case of the sulphate electrolyte, the best cathode deposits were formed when the solutions contained 5

or 7 g. free H_2SO_4 per 100 c.c.; more than 2.5 g. free H_2SO_4 per 100 c.c. solution seems to be necessary. The presence of free acid over 2.5 g. per 100 c.c. keeps the solution clear, and prevents the precipitation of basic salts, which if allowed to collect on the cathode deposit cause the tip to form non-adherent, large crystals. The cathode deposits formed from the stannous sulphate electrolyte containing 5 and 7 g. free H_2SO_4 per 100 c.c. were as satisfactory as those formed from stannous fluoride electrolyte.

Heating the electrolytes is beneficial in that the potential drop between the electrodes is reduced, and also a more adherent deposit is formed. Raising the temperature increases the effectiveness of the addition agent; a smaller amount of addition agent being required.

Dr. KERN's paper aroused a good deal of discussion. Prof. MATHERS dwelt at length upon the importance in the selection of the addition agent and suggested that Dr. Kern include in his paper a table of costs of addition agent per ton of tin deposited. A number of addition agents suggested by the author were too high priced for a refinery. Dr. LANDIS referred briefly to the large tin-refining plant at Perth Amboy, emphasizing the fact that electrolytic tin had long since passed beyond the purely experimental stage.

LEAD PLATING FROM SODIUM HYDROXIDE LEAD BATHS

The effect of addition agents in restraining the crystalline structure of the cathode deposits in alkaline lead baths was studied by FRANK C. MATHERS. Gum sandarac, gum galbanum and oleic acid were found to be very satisfactory, while other gums, rosins and fatty acids showed marked beneficial influences.

A satisfactory concentration of bath was found to be:

	Per Cent	Oz. per gal.
Crystallized lead acetate.....	7.3	9.7
Sodium hydroxide.....	20	27
Addition agent.....	0.3 to 1	0.4 to 1.32

As high a temperature as possible should be used. Better deposits are obtained at 90 deg. C. (194 deg. F.) than at 80 deg. C. (176 deg. F.). The current density at the anode should not be greater than 1 amp. per sq. dc. (9.7 amp. per sq. ft.). A cathode current density of 1.5 to 2 amp. per sq. dc. (14.1 to 18.8 amp. per sq. ft.) can be used, but the lower the current the better the deposit. At these current densities, the corrosion and deposition are approximately 100 per cent. The deposits are not as perfect as those from the acid lead baths, hence they are less satisfactory as protection against sulphuric acid.

In the discussion that followed, the early experiments of ANSON G. BETTS were referred to and it was suggested that, since our knowledge of electrolytic refining of metals had advanced rapidly within recent years, it would well repay the research men to repeat Mr. Betts' experiments with a view to improve upon the fluosilicate electrolyte.

A general debate followed on the theory of addition agents. Dr. FINK briefly reviewed the protective colloid theory and the colloid-electrolyte complex theory. Dr. BLUM recited a number of experiments in support of the protective colloid theory. Dr. HERING described tests he had carried out under the microscope. There seemed little doubt in his mind that the colloid particles were attracted to (or by) the points of the cathode crystals, necessitating a new direction or location of the next crystals. In one of his experiments he intro-

duced into the electrolyte both a positive and a negative colloid as addition agents. He expected the positive particles to collide with the negative particles, but under the microscope no such collisions could be detected. Dr. BLUM emphasized the importance of taking into account the relatively high current density at the points of the crystals. Dr. FINK suggested that further experiments be carried out with diaphragm cells, putting the addition agent in the cathode compartment and none in the anolyte; also reversing the procedure and putting the addition agents in the anolyte.

ELECTROLYTIC PRODUCTION OF HYDROGEN PEROXIDE

The literature on electrolytic hydrogen peroxide was briefly reviewed by F. W. SKERROW and E. R. STEIN before introducing their results on the experimental decomposition of sulphuric acid, sodium or potassium acid sulphate solutions. The current efficiencies with which persulphuric acid was formed were about the same in all three solutions. Of the materials experimented with as anode material, platinum was the only one offering possibilities of success, with the possible exception of manganese dioxide. Sodium persulphate solutions can apparently be produced to a much higher concentration than can persulphuric acid, without sacrifice of current efficiency. The potassium salt is, of course, obtained in solid form. Distillation of once recrystallized potassium persulphate with sulphuric acid and water gives reasonably high yields of hydrogen peroxide. Distillation of persulphuric acid or sodium persulphate solutions would need to be preceded by extremely rigorous purification to remove catalytic impurities.

INFLUENCE OF COPPER, MANGANESE AND CHROMIUM ON CORROSION OF THEIR IRON ALLOYS

Extensive data were presented by E. A. and L. T. RICHARDSON showing that there is a mutual action between manganese and copper in their effect upon the atmospheric corrosion of iron. Copper alone reduces the corrosion of pure iron and, to a still greater extent, the corrosion of steel. This is due to the effect of manganese, which enhances the effect of copper. If manganese is replaced by chromium, the effect is still more pronounced. It is shown that the red-short range in iron, due to the presence of copper, is removed by either manganese or chromium. It is believed that there is some relation between this red-short range and resistance to atmospheric corrosion. Based upon this, the film or inter-grain hypothesis is suggested to explain the corrosion resistance of these alloys.

Mr. AUPPERLE attacked the conclusions drawn and felt convinced, on the basis of his experience, that copper had no beneficial effect and did not prevent corrosion. Dr. RICHARDS took exception to the author's statement that "it has been known for years that commercially pure iron is red-short . . . and this red-shortness is due to copper." But Mr. Richardson maintained that every sample of commercially pure iron analyzed was found to contain copper. Dr. FINK pointed out that the presence of copper in the interfaces would depend to some extent upon the relative proportion and distribution of other impurities, such as sulphur or carbon in the iron samples. It is well known that the solubility of copper in iron is greatly influenced by such impurities. Accordingly, two samples of iron may con-

tain the same quantity of copper and yet the corrosion rate of the two be entirely different. Further metallographical investigations are needed.

SOLUTION OF METALS IN ACIDS

Inconsistent behavior of the metals in corrosion and acid solution phenomena on the basis of the electrochemical series were explained by W. D. RICHARDSON, who took into consideration a number of factors of which the principal were: solution tension, the hydrogen influence, the oxygen influence, the carbon dioxide influence, the cathode influence and the halogen influence.

Corrosion and solution of metals in acids may be considered as actions tending to go forward at rates proportional to solution tension and hydrogen ion concentration, but subject to the accelerating and retarding influence of many substances acting as catalyzers. Indications of the sensitiveness of various metals to the hydrogen and oxygen influences can be obtained by

The rates of solution of copper-bearing and pure open-hearth iron in nitric acid are catalyzed negatively by silver, copper and formaldehyde, but the rates of gray cast iron and semi-steel are catalyzed positively by the same three catalysts. No pronounced change of rate is shown by silver, copper or formaldehyde acting as catalysts on copper-bearing or pure open-hearth iron in sulphuric or hydrochloric acid. The same is true for silver and copper when acting on gray cast iron and semi-steel, but in contrast with this behavior, formaldehyde catalyzes these metals strongly in a negative direction in the non-oxidizing acids.

Platinum catalyzes the rates of copper-bearing and pure open-hearth iron positively in normal sulphuric and hydrochloric acids, and the action is more pronounced in the case of pure open-hearth iron than in the case of copper-bearing iron. On the contrary, the rates of these metals in normal nitric acid are catalyzed negatively by platinum. The rate for copper is not certainly catalyzed by any of the catalysts used. Nickel as a

their behavior when treated as couples in dilute acids and neutral salts and connected through a sensitive voltmeter or galvanometer.

Studying the behavior of metallic catalyzers on the rates of solution of copper-bearing iron, pure open-hearth iron, gray cast iron and semi-steel in normal sulphuric, hydrochloric and nitric acids at 16 deg. C., with several metallic catalyzers, it was found that the rolled metals in general showed a different and opposite behavior to that of the cast metals.

Again, the behavior of any of these metals in the non-oxidizing acids, sulphuric and hydrochloric, is as a rule different from the behavior in nitric acid. A similar rule holds for these metals in corrosion and also for solution in the above acids without catalyzers. Although the mode of action of a soluble organic catalyst, such as formaldehyde, is probably different from that of the metallic catalysts, nevertheless the opposite tendency in the case of different metals in oxidizing and non-oxidizing acids is revealed in this case also.

catalyst produces no effect on any of the metals in any of the acids except aluminum in hydrochloric acid. Aluminum is not affected by any of the catalysts in nitric or sulphuric acid. In normal hydrochloric acid the rate for aluminum is catalyzed strongly by nickel and still more strongly by platinum. A similar action might be expected in sulphuric acid and the lack of action in this case is probably due to the oxygen influence of sulphuric acid on aluminum.

Under conditions of corrosion the cast metals are relatively less attacked in the presence of much oxygen than the purer rolled metals. They are also relatively less attacked by an oxidizing acid, such as nitric, than by the non-oxidizing acids, sulphuric and hydrochloric. The catalysts, silver, copper and formaldehyde, all reverse this action and cause the rates of the cast metals in nitric acid to be increased and the rates of the copper-bearing and pure open-hearth irons to be reduced. Platinum, while catalyzing the rolled metals negatively in nitric acid, catalyzes them positively in sulphuric and hydrochloric acid, and is without action

on the cast metals in any acid. The failure of platinum to catalyze the cast metals is probably due to the evolution of poisons from the impure metals by the action of the acids.

After a brief discussion the members adjourned for luncheon in the rooms of the Cleveland Engineering Society.

Visits to Industrial Plants

Under the very able guidance of the chairman, Dr. N. K. Chaney, and W. R. Mott, a number of interesting visits were made to neighboring laboratories and factories. At the plant of the National Malleable Castings Co. the points of special attraction were the large Heroult steel furnaces, the malleabilizing process, the method of casting chains, the Bailly electric heat-treating furnace and the pulverized coal plant.

At the Guide Motor Lamp Mfg. Co.'s plant copper, silver and nickel plating vats were in operation. This is a new plant and a number of improvements, such as rotating cathodes, have been installed. The last plant visited Thursday afternoon was that of the U. S. Copper Products Co. Here an opportunity was offered to see a G.E. smothered arc furnace, for brass melting, in operation. Alongside of this was a Bailly brass furnace casting ingots about 3 ft. long and 3 in. in diameter. These ingots were subsequently forced over mandrels and drawn into tubing.

On Friday afternoon an elaborate visit was arranged to Nela Park. A number of the laboratories were taken in and with the aid of moving picture films the many intricate steps involved in the manufacture of the tungsten lamp, from ore to finished product, were explained. Opportunity was afforded to see the red hot tungsten wire being drawn through diamond dies, also assembling of the various lamp parts into the finished "Mazda."

Dr. ERNEST FOX NICHOLS, director of pure research at Nela, addressed the Society on "The Value of Research in Pure Science and Its Relation to Industry." It will be recalled that recently there has been a reorganization of Nela Research Laboratories into two sections, one of applied and the other of pure science. It is the latter which is under the direction of Dr. Nichols, formerly president of Dartmouth College and more recently professor of physics at Yale University. The speaker showed how science first came into industry through the testing of raw materials and final products. This was followed by industrial research, and this in turn by pure science research. The aim and purpose of the latter, he explained, are the extension of the boundaries of our knowledge, providing data of a fundamental nature which industrial research applies to the improvement of the product and reduction of its cost. Research in pure science, therefore, may go far afield, and sometimes a long period will elapse before the knowledge thus gained is used. In general, however, the time lag between a fundamental scientific discovery and its industrial application is becoming shorter and shorter. The pure scientist is being pushed by the industrial researcher. It is recognized, of course, that immediate profits come from industrial research, while the longer deferred dividends come from research in pure science. In the opinion of Dr. Nichols it is not only advisable for industry to give more attention to pure research, but it is a duty which it should assume in order that its service will be more efficient.

On Saturday afternoon the members visited the

Hazelett Storage Battery Co. Mr. Hazelett demonstrated his novel method of making very thin lead plates by casting the metal on a revolving drum. The plates obtained are decidedly thinner than any others heretofore produced for battery purposes and accordingly the ampere hours per unit weight of battery are far in excess of those of older types.

A trip through the factory of the Western Reserve Chemical Co. was arranged by Mr. Burwell, general manager of the plant. Phthalic acid was produced in large quantities by the oxidation of naphthalene with chromic acid. A novel electrolytic cell arranged in cascade was demonstrated; this was used for the regeneration of the spent chromic acid. The cost of making phthalic acid and benzoic acid is lower than by other processes.

E. S. MacPherson conducted the members of the society through the "gas factory" of the Ohio Chemical Co. It was one of the most attractive plants visited. Four gases were being turned out: oxygen, hydrogen, laughing gas and carbon dioxide. The electrolytic plant consists of one of the very first Levin cell installations. The oxygen analyzes 99.8 per cent pure. Neither the oxygen nor the hydrogen requires purification after leaving the cells. The carbonic acid is made from magnesite by a new process.

Canada's Paper and Pulp Exports

According to statistics issued by the Dominion Government, Canada's pulp and paper exports for July were valued at \$16,014,747, as compared with \$7,730,162 for the corresponding month a year ago, an increase of \$8,284,585, or more than 100 per cent. The shipments were made up as follows:

Paper and Pulp	Month of July	
	1919	1920
Paper	\$4,639,225	\$6,877,014
Chemical pulp	2,654,333	6,608,740
Mechanical pulp	436,604	2,528,993
Total	\$7,730,162	\$16,014,747

The paper exports during July, which included 9,789 cwt. of book paper, valued at \$110,596, and 1,219,439 cwt. of newsprint, valued at \$5,727,193, went to: United States, \$5,535,386; United Kingdom, \$425,949; other countries, \$915,679.

Exports of unmanufactured pulp wood show an increase in both volume and value for the month of July. They were: 1919—122,069 cords, value \$1,234,527; 1920—144,721 cords, value \$1,545,906.

APRIL-JULY SHIPMENTS

For the first four months of the current fiscal year Canada's pulp and paper exports reached a value of \$52,494,052, as compared with \$27,067,236 in April-July, 1919, a gain of \$25,426,816. They were greater by \$5,966,784 than the value of such exports in the complete year 1916-17—up to that time a record. Details of the four months' period follow:

Paper and Pulp	April-July	
	1919	1920
Paper	\$17,532,409	\$26,423,454
Chemical pulp	7,903,626	20,118,759
Mechanical pulp	1,631,201	5,951,839
Total	\$27,067,236	\$52,494,052

In April-July, 1920, the paper exports (which included 24,751 cwt. of book paper, valued at \$259,886, and 4,906,188 cwt. of newsprint, valued at \$21,916,549) went to: United States, \$20,998,774; United Kingdom, \$1,548,102; other countries, \$3,876,578.

Legal Notes

BY WELLINGTON GUSTIN

Palmer Potash Products Co.-Nebraska Potash Works Co. Controversy

The Supreme Court of Nebraska has affirmed the judgment in the controversy involving the Palmer Potash Products Co. and the Nebraska Potash Works Co. and others, except as to the amount of recovery, \$120,000. The court found no satisfactory basis for arriving at these figures and directed the lower court to have another accounting made.

Plaintiff's Clay and Irwin are members of the partnership called the Palmer Potash Products Co., each owning a one-third interest; Palmer owned the remaining interest. Palmer had purchased 1,240 acres of land in Sheridan County, Neb., on part of which were two lakes, the waters and underlying soil of which contained potash. Shortly after this purchase the partnership was formed for the purpose of producing potash from the waters and deposits of part of the larger lake, known as Ashburger Lake. It was contended that Palmer made an oral lease to the partnership for the term of twenty years to the southern part of the lake, with the right to remove and appropriate all the potash and other minerals in the lake and underneath the same. The lease further conveyed the right to use sufficient ground near the lake north of this lease for the necessary buildings, tanks and machinery, and for a right of way across the tract to the C. B. & Q. R.R. and for other necessary buildings and sidetracks. Palmer was to be paid a royalty of one-eighth of the proceeds of the potash produced. The oral lease is referred to in the partnership agreement, but this instrument does not provide for a 20-yr. limit to the lease nor for its own termination as agreed upon, and it further lacked definiteness as to the premises leased.

LAND SOLD AND ANOTHER LEASE MADE

After the execution of the agreement the partners constructed buildings and improvements on the margin of the lake and began extracting potash. In a somewhat crude manner, it was found, they extracted about thirteen tons of potash before lack of capital and dissensions between them prevented operations. The partners attempted to interest others who could provide necessary capital to make the payment upon the land coming due under Palmer's contract of purchase. Palmer finally assigned his interest in the land to Dr. Copsey of Alliance, Neb. It was alleged that Copsey bought the land from Palmer with full notice and knowledge of the partnership rights, and executed a lease to the lake to the Nebraska Potash Works Co., which also had full knowledge of plaintiffs' rights.

The plaintiffs brought suit to re-form the partnership agreement so as to show that the term of the partnership and the term of the lease should each be for twenty years, and when re-formed that the contract be specifically enforced and the defendants be enjoined from interfering with the use and occupancy of premises by the partnership and that title be confirmed and quieted in said partnership.

Defendants, the Nebraska Potash Works Co., Dr.

Copsey, Palmer and others, answered, claiming the written agreement between Palmer and his copartners was the only agreement made between the parties, denying the lease was for twenty years and alleged abandonment of the enterprise by the partnership. The cause was then removed by defendants from the state courts to the Federal court, but was afterward sent back from the Federal court. During this time the company sank wells in the lake and began pumping water and extracting potash.

In a supplemental petition the plaintiffs alleged in addition that Palmer was still the owner of the land; that the company had taken out from twelve to thirteen tons of potash per day, of the value of \$136 per ton; that the company had sunk over 400 wells in and about the lake, and that the partnership was indebted and that Palmer refuses to contribute his share in payment. The plaintiffs then asked that the lease of the company be canceled; that it be restrained from operating upon the premises; that the title be quieted in the partnership; that an accounting be taken of the potash extracted and the amount with interest be paid over to the partnership.

The trial court found that plaintiffs were entitled to all their claims and gave a judgment for \$120,000 with interest as damages sustained, caused by the trespass of defendants.

LOWER COURT UPHOLD

The Supreme Court has upheld the lower court, except as to the amount of the damages, finding there was not proper basis for determining this amount. It found that Copsey and the company had full knowledge of all the rights claimed by the partnership and therefore whatever rights they have acquired with such knowledge are subject to the rights of the partnership.

The agreement set forth in the opinion considered in connection with other evidence in the case the court held to be more than a mere license to extract potash and to confer upon the lessees the exclusive right to occupy the leased premises and remove potash.

The facts showed that the distribution of potash in waters of the lake was by no means uniform, presumably for the reason that evaporation proceeds as the waters move southward. The natural drainage is toward the south or southeast and the waters in the south end of the lake are much the richer. Defendants first confined their operations to that portion of the lake north of the dividing line, later invading the southern portion on the premises of the plaintiffs.

The court found that the evidence did not show abandonment by the lessees at the time defendants entered and removed mineral-bearing water from the leased premises.

Defendants contend that operations of the partnership were not interfered with and that there was no force used in the occupation of the south part of the lake, but the court says it seems obvious that the taking of actual possession and sinking of over 400 wells by the company in the south portion of the lake would effectively interfere with the raising of capital by the partners and the successful prosecution of their enterprise. It is true that if let alone the parties might have been forced to abandon their lease and thus lose all their rights, said the court, but as long as it was in existence no one had the right to interfere with them.

The question of its proper measure of damages gave the court much trouble. The general rule is that where

one having knowledge of the rights of another willfully trespasses upon and takes his property the owner is entitled to follow and recover it, even though its condition may have been changed and value added by the wrongdoer. On the other hand it was said if the taking had been under an honest mistake of fact and with no wrongful intention on the part of the trespasser the owner is entitled to recover only its value in its natural state.

Following the latter rule, in remanding the case to determine the proper damages, the court directs the ascertainment of the proportion of potash derived from the southern portion of the lake as near as possible; to charge Copsey and the company with the net proceeds of all potash derived from the same, less the royalty of one-eighth and the cost of extraction after the water was in the pipe line.

Buyer and Seller Held in Default Where Shipment Is Prevented by Embargo

The Appellate Division of the Supreme Court of New York has reversed judgment of the lower court in the action brought by Miller & Sons Co. against the E. M. Sergeant Co. and directed judgment for the latter.

The action arose out of a sale of twenty-four carloads of about 50,000 lb. each of Solvay brand 58 per cent light soda ash to the Miller company, for shipment in two installments each month, price f.o.b. Solvay, N. Y. There was a provision that default in any payment by the buyer gave the seller the right to cancel any undelivered portion of the contract.

The Government having possession of the railroads and having laid an embargo on freight, shipment deliveries for January, the first month of the contract, became practically impossible. The seller wrote buyer to get a special embargo permit from the Government, which the buyer failed to obtain upon application. The embargo was lifted Feb. 16, and the buyer then wrote the seller to ship immediately all soda ash due. The seller, in response to this, shipped two carloads due for February, but declined to ship the January installment upon the ground that having offered to deliver the two carloads in that month, and the buyer having failed to take the same, the shipper could not be required to deliver that installment in any other month.

Damages for failure to deliver the two cars in January were asked. The trial court adopted the contention of the buyer that the seller failed to deliver the two cars due under its order, that delivery was to be made in Philadelphia, where the buyer's plant was located, and that the words "f.o.b. Solvay, N. Y." were an element of the price and merely meant that the buyer was to pay the freight.

WHAT THE TERM F.O.B. MEANT

The higher court held that the words "f.o.b. Solvay, N. Y." did not have reference to the place of delivery, but held the place of delivery was not at the buyer's place of business in Philadelphia. It said the contract was silent as to the place of delivery, and where that is the case the store or factory of the seller or the place where the goods are kept is the place of delivery.

The buyer claims that it was the duty of the seller to deliver a total of twenty-four cars, and if because of contingencies beyond its control it could not make the delivery the buyer was entitled to require delivery at a later date when delivery was possible. But the court said the contract was not an entire contract for the sale

of twenty-four carloads, but was for the sale of twenty-four carloads in two installments each month, for which payment was to be made on each installment. Therefore it said the contract was severable and under the common law the failure of one of the parties to tender delivery or to pay for an installment would entitle the party to rescind the entire contract. If the parties thereafter proceeded under the contract the right to rescind would be lost. This rule is now changed in New York State by the personal property statute so that it depends in each case on the terms of the contract and circumstances whether the breach "is so material as to justify the injured party in refusing to proceed further and suing for damages for breach of the entire contract, or whether the breach is severable, giving rise to a claim for compensation for any loss, but not to a right to treat the whole contract as broken."

As might have been done, neither party sought to excuse its failure because of contingencies beyond its control; in fact, each claimed the other failed to perform, there being no failure on their own part. The sole remaining question is which party did fail to perform. It being found that Solvay, N. Y., was the place of delivery, when the seller notified the buyer that the goods were ready for delivery and asked buyer to secure embargo permit for shipping, the seller performed, and the failure of the buyer to accept the delivery was a breach of the contract on its part. Therefore it has no claim for the January installment and judgment was directed against it.

Where Buyer May Not Enforce Contract for Deliveries

In a recent decision of the Supreme Judicial Court of Massachusetts in the case of Lionel Samuels against the W. H. Miner Chocolate Co. the court holds that the buyer had broken the contract by omitting to forward his check and to send orders, which justified the seller's cancellation of the contract.

The contract was for the purchase and delivery of 2,000 bbl. of cocoa at 11½c. per lb., to be shipped by the chocolate company at such times and in such amounts, not to exceed 100 bbl. per week, as the buyer should direct. The buyer was not obliged to draw each and every week or at any particular time. The whole 2,000 bbl. was to be ordered shipped during the year 1917, and payment for each shipment was to be made in advance.

There was some delay on the seller's part in shipping during July and August. But this delay was waived by the buyer. In September the buyer made excuses for not ordering, and the latter part of said month the seller notified the buyer to furnish the orders under the contract or same would be canceled, and finally in October the seller canceled the contract.

When the contract was canceled there remained but eleven weeks of the contract period, with 1,485 bbl. unorderd, and the buyer was not obligated to ship more than 100 bbl. per week. Now, in addition to this failure to send orders as required by the contract there was a further neglect on the buyer's part to comply with the agreement by his failure to forward a check for each lot before shipment was made.

The court found that buyer's breach in these matters went to the essence of the contract and that it justified the seller in canceling the rest of the order. The judgment of the lower court was upheld.

The Channel Process of Making Carbon Black

Details of Plant Construction for Channel Process—Condensing Building—Gas Transmission—Channels—Hoppers, Scrapers and Conveyors—Burners—Driving Mechanism and Accessories

By ROY O. NEAL

IN COMMERCIAL practice there are four different processes of manufacturing carbon black from natural gas—viz., the channel system, the small rotating disk, the roller or rotating cylinder, and the large plate processes. The main points of difference in these methods is in the size and shape of the surface upon which the carbon is collected and the rate at which the moving devices actuate. The channel process is probably the best method and is the most extensively used. Classified according to the quantity of carbon black produced, the order is as follows: Channel, small rotating disk, large plate, and roller processes. At the present time the production of carbon black by cracking or thermal decomposition methods is not extensive.

THE CONDENSING BUILDINGS OF THE CHANNEL PROCESS

The buildings in which the channels and burners are installed are made of 24-gage sheet iron, held by wire to a steel frame made of $\frac{1}{2} \times 1\frac{1}{2} \times 1\frac{1}{2}$ -in. angle iron. Fig. 1 shows the structural details of a typical building (sometimes referred to as the condensing building). The ridge piece does not extend the entire length of the building, as spaces are left to allow the escape of the gases of combustion. The ridge pieces are flexibly attached so that spaces can be changed, and consequently the draught regulated. In the design of some plants chimneys are provided. Slits or slide doors are located along the bottom of the buildings for controlling the air entering the buildings, but usually are not adjusted to meet the various weather conditions. A door at each end and one or two doors on both sides furnish access to the interior of the condensing buildings. With buildings having one table—that is, buildings that have one

group of channels bolted together—the dimensions are 8 or 10 ft. in width by 80 to 115 ft. in length. With two-table buildings, the dimensions vary from 18 to 20 ft. in width and from 80 to 115 ft. in length.

The buildings are arranged in parallel rows at right angles to and on both sides of an alley. The alley-way is about 15 ft. wide and buildings are from 3 to 5 ft. apart. The number of one-table buildings per unit—that is, whose power is furnished by one engine—varies from 24 to 30. In some districts, particularly Louisiana, a larger yield has been obtained with one-table buildings on account of the atmospheric temperature. With two-table buildings, the number of buildings per unit varies from 12 to 16. The units have a capacity ranging from 60 bbl., or 3,000 lb., to 100 bbl., or 5,000 lb. of carbon black per day. The largest plant that the writer inspected was made up of six units and consequently had six packing houses, six engines for furnishing power and six main driver shafts. The entire plant consisted of 180 condensing houses.

GAS TRANSMISSION

The gas coming from the wells, discharge from gasoline plant or gas transportation mains, is reduced in pressure by suitable regulators. After passing through the regulator the gas goes through a gasometer tank that is partially filled with water. Details of a typical gasometer are shown in Fig. 2. It consists of two tanks made of boiler plate, one inverted in the other. The gas is passed into the inverted tank and held by a water seal. The pressure of the gas blowing from the gasometer will be determined by the weights on top of the tank and the height to which it rises. The inverted tank is connected to a butterfly valve on the intake gas line by means of a lever arm, so that, as the pressure increases, the inverted drum of the gasometer tank rises

EDITOR'S NOTE.—The present description and others that will be published shortly are published by permission of the director of the Bureau of Mines in advance of the report of the Bureau.

and the butterfly valve is closed. The flow of gas is controlled by the gasometer so that the pressure of the gas upon discharge will have a pressure of less than 1 oz. per sq. in.

In a plant having one-table condensing buildings, the gas is piped from the gasometer tank to a 24-in. distribution pipe made of riveted boiler plate, which lies in the center of the alley. Two 4-in. lines connect the distributor to each building, each of which is provided with a 4-in. gate valve. In the buildings a 1-in. pipe is connected to a 4-in. line every 8 ft. Between the 4-in. pipes a 1-in. rod or riser 3 in. high is welded, upon which the overhead channel work is supported. This arrangement is shown in Fig. 4.

In another design, an 8-in. gas line completely encircles the condensing buildings, to which two 4-in. inlet pipes are connected at each end of the building. Fig. 3 shows an installation of this description. The method of piping in all cases must be capable of distributing the gas evenly throughout the entire unit and the fact that the gas is held under such low pressure demands considerable attention.

The channels upon which the carbon black is deposited

FIG. 1. DETAILS OF CARBON BLACK CONDENSING PLANT

are made of mild steel, 7 to 8 in. wide and weighing about 12½ lb. per linear foot. The channels are supported by trucks that run on overhead rails. The channels, trucks, rails and other accessories are held up by 1½-in. standard pipe that rests either on concrete piers or upon the gas-distributing pipes. An upright pipe is provided at approximately every 4 ft. They are stabilized by 1 x ½-in. cross-strap iron braces.

At the top of each upright support is placed a small cast-iron rail chair which carries the rails. The rails are made of steel weighing from 16 to 20 lb. per yd. Running on the rails are 10-in. double gudgeon truck wheels. The wheel has lugs projecting out from the axis on each side which regulate its position, and it is held rigid longitudinally by two short lengths of 2 x 2-in. angle iron, although it can oscillate within a fixed distance in the line of direction of the rails.

Attached to the angle iron on both sides of the truck wheel are transverse channel beams (6½ lb. per ft.), to which the channels upon which the carbon black is deposited are bolted. Most of the plants have eight rows of channels on each trestle. These trestles are about 6 ft. wide and are called tables. An installation of this type is shown in Figs. 5 and 6, the views having been taken at a plant under construction. The channels are bolted together in lengths as great as 100 ft., while the trestle work is from 10 to 15 ft. longer to allow for the oscillations of the table.

DETAILS OF GASOMETER TANK

Below the channels the carbon-collecting hoppers are located, being spaced approximately 4 ft. apart. The hopper is made up of three parts, the crown, body and base. The crown is supported upon the trestle by a 1 x 1½ in. angle on each side and sits loosely in the body, which is about 6 ft. in width in the upper portion and tapers down to about 10 in. The base is about 15 in. high and carries the conveyor pipe at its lower extremity.

All three parts of the hopper are 6 in. wide, and the crown contains four notches which retain the scrapers. (See Fig. 8.)

FIG. 3. MAIN SHAFT AND SUPPORTS

the shaft in helicoidal form and is held rigid by $\frac{1}{2}$ -in. rivets. Fig. 7 shows the details of a spider bearing, truck wheel and rail chairs. Some carbon black operators prefer to purchase spiral conveyors from machine shops where helicoid is rolled from a single strip of metal before the pipe is inserted. This type of conveyor is strong, and resists to the full strength of the metal the lateral pressure due to pushing the material forward.

At the discharge end of each conveyor is an overflow

FIG. 8. ASSEMBLY DRAWING OF TABLE OF CHANNELS

tee which consists of a short pipe connected to the conveyor at a 30 deg. angle. This tee carries a sheet-iron cap. Below the tee and connected at a right angle to the conveyor is a pipe about 5 in. long and crimped at the end to allow the collected carbon to be transmitted to the main conveyors that lie on each side of the alley.

BURNERS

The space between hoppers constitutes one section of the trestle. In this space are located the burners. The gas is delivered to the section by a $1\frac{1}{2}$ -in. pipe, to which is connected a $\frac{3}{4}$ -in. pipe that carries the $\frac{1}{2}$ -in. burner. The burner is parallel and about 3 to 4 in. below the channels. Each burner holds from eight to ten lava tips. A typical 60-bbl. plant would contain eight lava tips per burner, sixty-four lava tips per section, 1,600 lava tips per building, 38,400 lava tips per plant having twenty-four buildings.

The lava tips are made of a selected grade of steatite, that is easily machined in its green condition to any desired form by turning, milling and grinding. It is then heated to a temperature of about 2,000 deg. F., thus becoming hard and strong. Most of the manufacturers of lava tips are located in the vicinity of Chattanooga, Tenn.

There are a great variety of tips used, but the more common type burns 4 to 14 cu.ft. of gas per hr. The requisite for good tips is that they should produce uniformity of flame and have uniform gas consumption. A typical lava tip has a slot 0.20 in. deep and 9.934 in. wide. The lava tips are slightly tapered so that by drilling a hole slightly larger than its smallest outside diameter in the burner pipe, the tips can be securely held and made gas tight by the application of white lead. In Fig. 8 is given the general arrangement of burners, hopper, conveyors and channels.

Each unit is equipped with a separate engine which is usually about 20 hp. in capacity and is of the internal gas combustion, two-cycle type. Some factories use a simple steam engine, but instead of utilizing steam for

work, allow the high pressure gas before passing through the regulators to expand and furnish power for the expansion engine.¹ This arrangement effects an appreciable saving in the cost of operation. The engine is belt-connected to a drive shaft through which power is transmitted to the conveyors, elevators, bolting machines, packing machines and the reversing gear shift that actuates the channels. These details are shown in a plan view of a complete carbon black plant in Fig. 9.

A working drawing of a reversing gear shift is shown in Fig. 10. Power for the device is transmitted by a belt from the overhead drive shaft. Pulley *d* is connected to pinion *b* by means of a sleeve; pulley *e* is an idler and *f* actuates pinion *c* through a collar. A carriage traveling along the threaded shaft *g* shifts the belt from *f* over *e* to pulley *d* periodically by means of a lever system, consequently changing the direction of rotation of bevel gear *a*. This change takes place about every fifteen minutes. The gear that

is keyed to shaft located in center of alley meshes with the worm gear *h*. Another arrangement with a worm gear drive is given in Fig. 11.

The main shaft that moves the channels extends the entire length of the alley and is usually 3 or 4 in. in diameter. It is supported by trestles 6 ft. high and made of channel steel. Details of a support are given in Fig. 7. There is a support with a pillow block for each pair of buildings. Couplings are placed every 16 or 20 ft.

Over each support is a thirteen-tooth flanged pinion for engaging teeth in a rack or cog plate that is on the under side of an inverted tee steel beam connecting end trucks in opposite buildings. The rack is made of cast iron, containing forty-two teeth and is about 62 in. long. A stirrup of iron or roller is used to assure engagement of the rack and pinion. The entire table of channels and scrapers is moved by this rack and pinion, the channels having a straight line reciprocating motion of 55 to 60 in. which occupies a period of time of fifteen minutes. In a typical 60-bbl. plant there is approximately 200 tons of iron and steel in the condensing buildings, which does not include frame work or sheet iron covering that enter in the construction of the buildings.

The conveyors are drawn by a shaft belt connected to the main power shaft in the engine room. One 1-in. shaft lies on each side of the alley and transmits power to the conveyors in the condensate buildings by means of bevel gears. Another conveyor runs along each side of the alley that is chain driven by a sprocket wheel on the 1-in. shaft. These conveyors carry all of the black from the buildings to an elevator which is simply an endless chain having buckets attached. The elevator is enclosed in a 16-gage galvanized sheet iron box.

The grit, scale and hard particles in the carbon black are removed by the bolting machines that vary greatly

¹See Technical Paper 222, p. 20, W. P. Dykema and Roy O. Neal, U. S. Bureau of Mines, 1919.

in design. The practice is also different at various factories. Some operators pass the carbon through two bolters, some through one, while others are not equipped with machines. At a few plants there is an apparatus fitted with coarse wire for removing bolts, pieces of iron and similar articles, which is called a "scalper." The bolting machine may be of the horizontal or vertical

type, although the latter design is more commonly employed.

Details of a machine that is largely used are given in Fig. 12. It is made of 20-gage galvanized iron. The size of the steel screen used varies from 45 to 60 mesh, which is held up by a heavy wire as reinforcement. The screen is attached to a cylinder that can be removed through

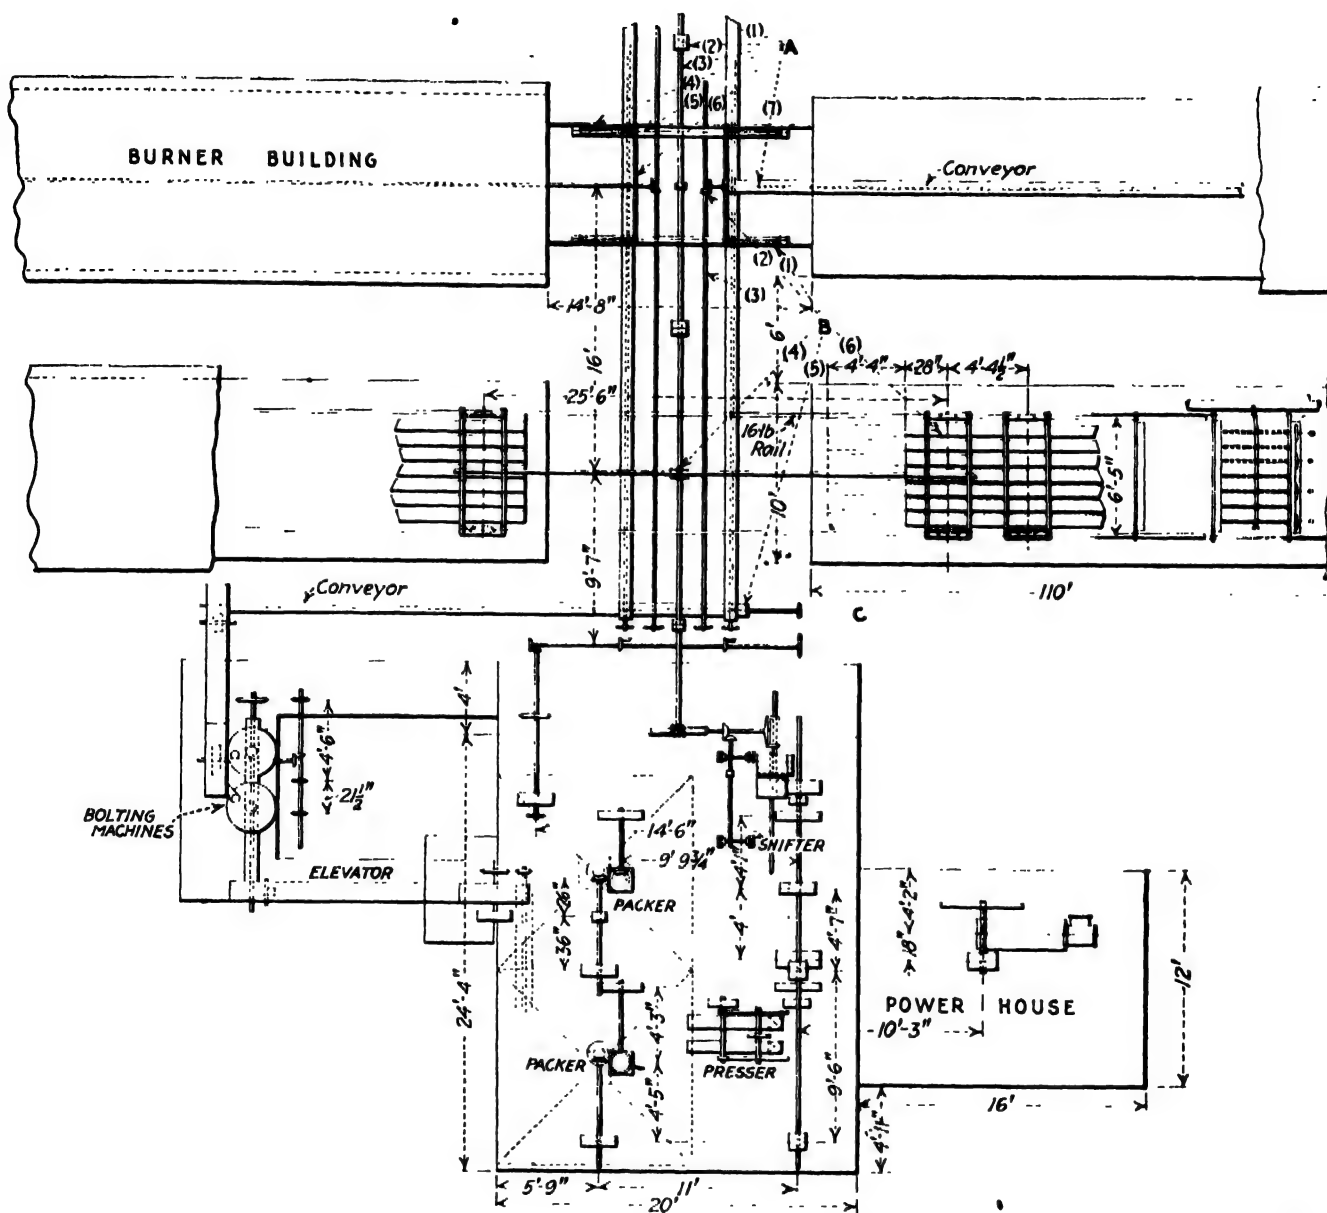

FIG. 9. PLAN OF TYPICAL PLANT

A1—8-in. spiral conveyor receives material from conveyor extending through entire length of each building.

A2—On main drive shaft couplings are placed, spaced 16 ft.

A3—3-in. main drive shaft, extending entire length of alley between buildings.

A4—16-in. rail of track on trestles in opposite buildings extends continuously across alley, connecting and bracing opposite trestles.

A5—A two bent steel trestle in alley between opposite buildings affords a brace for buildings and supports main drive shaft and conveyors.

A8— $\frac{3}{4}$ x 2 x 2-in. angle iron tying trestle bents at top and supporting 16-16 rail crossing alley and connecting opposite buildings.

B1—2 pieces $\frac{1}{2} \times 2 \times 2$ -in. angle iron forming batter post for trestle.

B2—5½-in.-20-tooth cog on conveyor drive shaft engaging 10-in.-40-tooth cog on shaft of conveyor extending through building.

B3—Drive shaft (1-in. Stand. G. P.) for conveyors which extend entire length of each building.

B4—Flanged pinion to engage teeth in G. I. cog plate on under-

side of inverted T-steel connecting end trucks in opposite buildings
(6 in. diameter, 3½ in. face, 13 teeth.)

135—Conveyor from conveyors in alley to elevator.

136—Channel iron placed with flanges turned upward and spaced 10 in. o.c. Bolted to under side of trucks. Seven pieces of 8 x 21 x 18 in.

"To each bent is fastened a sheet iron hopper held in position by being wired to angle irons between bents.

Rent posts are made of gas pipe spaced 6 ft. 6 in. wide and held in position at top by 1½ x 1½-in. angle iron.

Each hopper tapers toward its lower end and deposits its contents into a spiral conveyor. Between hoppers is arranged a system of gas pipes, which provides burning gas flames under each channel.

Rents are spaced 5 in. o.c. on top and 50½ in. on bottom and held in position on top by means of 1½ x 1½-in. angle irons.

Along center of each hopper is arranged seven scrapers, which bear on under side of channels to which trucks are bolted, pressure being obtained by means of weights on outer end of rods. Double gudgeon truck wheels, 1½ in. bearing x 10 in. diameter, made by Styles Mfg. Co.

the drop door. A shaft having a spider with six arms, each of which carry two fiber brushes, forces the carbon black through the screen. The product not passing through the screen is discarded periodically as waste material.

STORAGE BINS AND PACKERS

The storage bins are made of galvanized iron and vary in size. They are tapering-shaped hoppers located over the packers. Some operators use bins of sufficient

FIG. 10. REVERSING GEAR SHIFT

size to store two or three days' production, in order to eliminate any shut-down due to trouble in the packing room or to hold the carbon black made on Sunday, as in some plants the packers operate only six days per week.

The packers are very similar to those used at sugar refineries. An auger works inside of a tight sheet steel tube, pressing the carbon black into a paper sack. The auger is designed to stop the waste of the free-flowing stock running out between the blades of the auger when the packer is stopped for changing sacks. The stock, when passing through the auger, keeps the hinged gates folded parallel to and against the top auger blades. When the auger stops, the coil springs force the gates downward against the carbon lodged between the blades, not closing the passageway completely, but holding it back sufficiently to prevent leakage. The machine is gaged to pack a uniform amount in each sack, which is

FIG. 11. DRIVING WORM GEAR CHANNEL PROCESS

usually 12½ lb., or a quarter of a barrel. In some cases, especially for export trade, the sacks contain 15 lb. The device starts by a simple movement of a lever which causes the bevel gears to mesh, and stops automatically when the sack has been filled with 12½ lb. of carbon black. The packer is connected to a storage bin by a spout.

A 60-bbl. plant usually is equipped with four packers that fill a sack in approximately fifteen minutes. The inner shaft rotates slowly in order to effect the proper separation of the carbon black from the air, in which it floats or holds mechanically. The problem of packing is to separate the black from the air as far as is commercially practicable.

The sacks are tied, and in most plants slightly compressed. The compressor consists of a steel plate box,

FIG. 12. DETAILS OF A BOLTING MACHINE

in which a plunger, actuated by a crank shaft or eccentric, travels. The sides of the sack are flattened to facilitate storing and transporting. After compressing, another paper sack is placed over the package.

The sacks of carbon black are removed from the packing building by trucks to the warehouse. If the black is to be sold to export trade, it is packed in wooden boxes 3 x 3 x 2 ft., holding from twelve to fifteen sacks each. The warehouses are located on the main transportation line, or on a narrow-gage railroad, that has electric or gasoline engine-driven trucks which convey the product to a transfer point. The warehouses differ greatly in size. At one plant that was visited by the writer, a stock of 35,000 sacks of black was stored, with spaces available for an equivalent quantity more. The warehouses may be open wooden frame buildings with corrugated sheet iron roofs, or completely inclosed sheet-iron buildings.

The disk, plate and cylinder processes will be described in a subsequent issue.

Foundry Methods for Light Aluminum:Copper Alloys

A Statement of Melting and Alloying Practice in Vogue in America for the Production of No. 12 Alloy, and a Discussion of the Apparent Advantages and Disadvantages in the Use of Copper or Various Copper-Rich Hardeners

BY ROBERT J. ANDERSON

IN MANUFACTURING light aluminum:copper alloys for sand castings and for die-casting purposes several distinct problems exist which are of interest to aluminum foundries. These problems are those which are connected (1) with the method of alloying copper and aluminum so as to produce alloys containing from, say, 2.0 to 14.0 per cent copper; (2) with furnace temperatures; and (3) with melting practice. Casting losses, oxidation and dross losses, and melting costs may vary considerably, depending upon the mode of manufacture of these alloys. The present article deals with the commercial manufacture of light aluminum:copper alloys in the United States, but so-called aluminum bronzes are not considered. In addition, experiments made in studying methods of preparing No. 12 alloy are described.

LIGHT ALUMINUM:COPPER ALLOYS

In aluminum founding the light aluminum:copper alloys are preferred for general casting purposes, and alloys of aluminum with other metals are not actually used to an important extent. The usual alloy employed in the United States for sand castings is one containing approximately 92.0 per cent aluminum and 8.0 per cent copper, and in fact this is virtually the present standard casting alloy. There are, however, several other distinct binary aluminum:copper alloys employed for commercial castings; these alloys contain from 2.0 to 14.0 per cent copper and remainder aluminum. An alloy containing 96.0 per cent aluminum and 4.0 per cent copper is used extensively in the United States for sand-cast cooking utensils and for some automotive castings; alloys containing 9.0 to 10.5 per cent copper and remainder aluminum are used for certain automotive castings, principally manifolds and pistons. A few alloys containing, say, 12.0 to 14.0 per cent are employed for particular purposes in England. In the United States the consensus of opinion among aluminum foundries and automotive engineers is that the alloy containing about 92.0 per cent aluminum and 8.0 per cent copper (known in the trade as No. 12 alloy) is the best available for general casting purposes.

According to a recent survey by the Bureau of Mines, it is estimated that about 97 per cent of the so-called aluminum castings made today are poured from No. 12 alloy. The greater part of the remainder is cast from other aluminum:copper alloys, and the balance from other binary and complex alloys. There are a number of other aluminum alloys used for castings such as aluminum:magnesium, aluminum:zinc, aluminum:copper:zinc, aluminum:copper:tin, and aluminum:copper:manganese alloys; however, the total annual

output of castings made from these alloys is small with respect to the output of No. 12 alloy castings.

COMMERCIAL NO. 12 ALLOY

Strictly speaking, commercial No. 12 alloy is not a simple binary alloy in most foundries because of the usual presence of appreciable amounts of certain impurities, notably iron. Where the iron is high, and this element is frequently present in amount up to 2.0 per cent, the alloy should be properly regarded as a ternary aluminum:copper:iron alloy. This distinction may appear to be academic, but it really is not, because increasing amounts of iron markedly affect the properties of the alloy. As a matter of fact the iron content of most of the No. 12 alloy cast today ranges from 0.75 to 1.50 per cent, with an average of about 1 per cent.

No. 12 alloy is made up in foundries for casting purposes by a number of methods, and a variety of materials may be employed in the melting charges, and No. 12 casting ingot is marketed by primary and secondary ingot makers. Primary No. 12 ingot is made ordinarily by aluminum producers directly from virgin metals, while secondary No. 12 ingot is run down by smelters and refiners from aluminum-alloy borings and turnings, scrap castings, aluminum clippings, and other aluminum and aluminum-alloy scrap. In the foundry the methods employed for the manufacture of No. 12 alloy vary considerably, depending upon individual preferences, upon conditions and prices in the primary and secondary aluminum markets, and upon other factors. From the metallurgical standpoint, however, the principal consideration involved is the method of introducing the copper. This is especially important in foundry practice because the method employed for making the alloy affects dross losses, oxidation, shrinkage and casting losses, as well as costs.

PRESENT FOUNDRY METHODS

At the present time there are two well-defined methods used for alloying copper with aluminum in the commercial manufacture of light aluminum:copper alloys for casting purposes in the foundry; conflicting opinions have been expressed as to which one of these methods is the more advantageous. The methods employed in commercial practice call for the use of (1) copper, and (2) a rich copper:aluminum alloy such as 33:67 or 50:50 alloy.

Some foundries prefer to make No. 12 alloy or other light aluminum:copper alloys by the addition of solid copper to liquid aluminum. This is quite a common practice in small foundries, but it is not used much in the large plants. Where copper as such is employed the usual practice is to melt the aluminum first, and then add the requisite amount of copper later. Thus, for a small heat of No. 12 alloy, say 100 lb., the

Published by permission of the Director, U. S. Bureau of Mines.
*Metallurgist, U. S. Bureau of Mines, Pittsburgh, Pa.
†Anderson, R. J., "Special and Commercial Light Aluminum Alloys," U. S. Bureau of Mines, War Minerals Investigations Series, Bull. No. 14, April, 1919.

melter will first liquefy 92 lb. of aluminum in a crucible and then add 8 lb. of light sheet copper. The copper is alloyed by diffusion and partly by solution. In foundry practice copper is usually employed in the form of clean light-gage sheet, clippings and punchings, light sheet scrap, or scrap wire. Rarely, if ever, is the copper added in the form of ingot or cake copper, because large, massive pieces require too long a period of time for solution.

USE OF SOLID COPPER

Copper as such is used because it is supposed to alloy satisfactorily, and to save the cost of preparing the rich alloys, such as 33:67 and 50:50 copper:aluminum. There are some apparent advantages in the use of copper direct, but at the same time some obvious objections. While many conflicting opinions have been expressed in considering the use of copper rather than a rich alloy, the most apparent advantage in the former would appear to lie in the saving made by obviating the cost of manufacture of a rich alloy.

The presumed difficulty of dissolving solid copper in liquid aluminum has been offered as an objection, but there is no basis in fact for this, because copper, in the form of light-gage punchings and sheet, goes into solution in aluminum quite rapidly at 700 deg. C. (considerably below normal furnace temperatures in aluminum-melting practice). More massive pieces of copper dissolve more slowly at low temperatures but go into solution fairly rapidly at 900 deg. C., as has been shown by experiment.¹ Hence, if bulky and heavy copper is used, the melting charges must be heated to rather high temperatures, and this is decidedly inadvisable for aluminum alloys—where high furnace temperatures are permitted in melting the resultant castings are likely to be porous, unsound and leaky because of gas absorption and oxidation of the alloy. In case the copper is dirty or greasy it is advisable to boil it in sodium hydroxide, as is done by some foundries, but cleaning for the mere sake of securing a bright surface simply adds to the production costs. If the copper is covered with a considerable layer of copper oxide (Cu_2O) or if the copper oxide content of the copper is high an appreciable thermit reaction will take place when the solid metal is added to liquid aluminum; badly oxidized copper should not be used, as it thus increases the dross losses.

ADVANTAGES AND DISADVANTAGES OF USING SOLID COPPER RATHER THAN A RICH COPPER ALLOY

A few foundries prefer to use copper rather than a rich alloy on the ground that the former minimizes errors in weighing, but this seems to be a dubious advantage, if any exists. Some foundries have had difficulty with porosity and excessive shrinkage in castings made by the use of copper direct, while others have experienced non-uniformity of product, where the castings run "hard" and "soft." Both porosity and shrinkage might be readily traced to causes other than the method of making the alloy, and since molding and melting practice influence these defects it is not possible to deal with this objection without more complete data. Heterogeneity of composition (hard and soft castings) can logically follow from the use of copper either because of failure to secure complete solution
